These "value" responses seem inconsistent when coupled with the fact that only 3 of the 10 respondents say that they use CIM XML imports as the starting point of their external models. (All 3 were RCs.) It may be that those that use the capability only to export models say it is essential because they are required to provide CIM XML models to others (e.g., their RCs). Or, it could be that the respondents placed a high value on this capability because CIM XML will very likely be the model exchange language of the future and they have plans to use it. Unfortunately, the survey questions related to CIM XML were not as thorough and concise as they could have been.

In an attempt to better understand the apparent inconsistencies in the survey responses, the task force contacted for follow-up questions 3 of the respondents that have used their CIM XML import/export capabilities in their modeling activities. All of those contacted were RCs who have some of the largest network models in the survey. Two of the 3 had used CIM XML models that were provided to them by other entities for major internal and external model additions and replacements, and one has just used a CIM XML model for internal model updates. Some of the interesting pieces of information that came from the follow-up questions are summarized below:

- CIM XML files have been used infrequently and only for major model additions and replacements. None of the 3 had used it for relatively small changes (e.g., incremental updates) that would be considered as "routine" model maintenance.
- It is not a "plug and play" process and generally takes weeks or months to implement changes. For instance, one respondent stated that some CIM XML files require one to two weeks to complete the import, conversion, and some basic model validation. When there is a problem with the source CIM XML file (because of data, syntax, or schema), they must request an updated version of the source model. Every request for an updated source model and the subsequent import/conversion requires two

to three weeks, so multiple requests for an updated source model can easily add three months (or more) to a project before the model reduction and model merge steps can even begin.

- Merging a CIM XML model into an existing network model is an involved process that entails both automated and manual work. The respondents have had to write special software tools to aid in their efforts.
- Some entities cannot dump their models in CIM XML output files to other entities because their EMSs do not have that capability. In that case, the receiving entities must accept files in other formats and use them to update their models.
- None of those contacted has used the CIM XML models for measurement mapping. This has done manually or by supplemental data files and tools that were created for that purpose.
- The import of the CIM XML model does not provide 100 percent of what is needed for a complete model. Custom programming and/or manual data entry is often needed to populate missing or incorrect data in the source model.

Some of the major technical issues that the respondents said they had to overcome were:

- CIM XML files do not always comply with the NERC CPSM.
- There is some room for interpretation of the CIM standard, and, as a result, certain data are not put in the data classes or attributes where another vendor would expect to find them.
- Vendor tools are not always compatible with the exact version of CIM that was used to create the source model.
- Attempts to resolve data issues by browsing XML files are nearly impossible because the files are difficult to read. Better tools are needed to review the CIM XML files for troubleshooting.
- CIM XML files are extremely large. The large file sizes stress (and sometimes break) the tools that are used to import and convert the models.

The CIM definition for power system modeling is still under development and is evolving. Most of the major EMS vendors are participating in interoperability tests to work out the existing bugs and to test new features (e.g., incremental updates). There is also an active users group that has been created to develop the CIM related standards (http://www.cimusers.org). However, despite the push in the industry to adopt and use CIM XML, the survey responses suggest that CIM XML model exchange is not yet common practice. Only 42 percent (17 out of 41) of the respondents can even export their models in CIM XML files. And only 58 percent (10 out of 17) of those that have it, and 24 percent (10 out of 41) of all survey respondents, are using it at all. Despite these challenges, the respondents that were contacted expect to be using CIM XML to a greater extent in the future as technical problems are solved and users and EMS vendors create new tools.

Recommendations for New Reliability Standards

RTBPTF makes no recommendations at this time for reliability standards related to modeling practices. However, RTBPTF recommends that additional analysis be done in several modeling areas from which recommendations for new reliability standards may be forthcoming.

Recommendation – A16

Investigate processes and procedures for internal system update and external data exchange, including CIM XML models.

Areas Requiring More Analysis

RTBPTF has identified the following areas for more analysis:

- Clarity of fundamental definitions of terms used in the existing NERC reliability standards
- Processes and procedures for grid change notification and data exchange
- Development of external system modeling guidelines
- Exchange of CIM XML models

Clarity of Fundamental Definitions

RCs and other entities have been charged with monitoring their "bulk electric systems" and having network models that provide a "wide-area view." However, existing definitions of "bulk electric system," "bulk power system," and "wide-area view" are vague and open to interpretation as evidenced by the significant variation in models reported in the Real-Time Tools Survey. An entity's interpretation of these definitions can significantly impact the size and contents of the network model it uses for its real-time applications, and, consequently, the maintenance efforts needed to keep that model current. The vagueness of these terms may partially explain some of the large differences in model sizes and characteristics that were identified in Section 4.1, Model Characteristics, (e.g., external-bus-to-total-bus ratios, etc.). NERC should clearly define these terms because their potential impact on network modeling decisions.[21] For more discussion of the need to define these terms, please see the Introduction to this report and Section 2.2, Visualization Techniques.

[21] Lack of specificity in these terms was also pointed out in the *FERC Staff Assessment*.

Recommendation – I5

Develop system models and standards for exchange of model information.

Grid Change Notification and Model Data Exchange

The power system models used to provide a wide-area view can require extensive modeling both inside and outside the reliability footprint of an RC or TOP. The external portions of the models are often more difficult to maintain than the internal portions because of the problems related to 1) knowing when something in the grid external to the reliability footprint has changed or is going to change (e.g., a new line or station is added) and 2) being able to obtain required modeling and real-time data from external entities.

As noted in the analysis above related to notification and other procedures among reliability entities, updating of external models is greatly facilitated when there are processes and procedures in place to:

- Prescribe how entities notify each other about pending grid changes far enough in the future to allow updating of real-time network models in a timely manner; and
- Identify the types of data (both real-time and modeling) that are to be exchanged, the time frames for data exchange, acceptable data exchange media and formats, required non-disclosure agreements, etc.

Many survey respondents have at least some data exchange/update processes and procedures in place with entities within their reliability footprints (i.e., their internal model areas), but few if any have such procedures in place for all of the external entities that border and/or have significant impact on their reliability footprints.

RTBPTF recommends that a task force be created to investigate grid change notification and real-time model and ICCP data-exchange processes and procedures. This task force would identify and recommend minimum standards for real-time models and data exchange similar to some of the existing "MOD" standards related to steady-state models (e.g., MOD-010, MOD-011, etc.) but more appropriate for the types of models and supplemental information required by real-time EMS applications such as the state estimator and contingency analysis. The task force should address the following:

- Grid change notification processes and procedures,
- Real-time data exchange (i.e., ICCP data) processes and procedures (a good foundation for these procedures can be found in the documents posted on the NERC DEWG website.)

- Model data exchange processes and procedures (network models and other information needed to support these models such as station schematics, regional maps, etc.), and
- Any required legal agreements needed to facilitate information exchange (non-disclosure, etc.).

External Model Development

It is evident that survey respondents have used a wide range of approaches to create external models and determine what measurements to include in them. Some external models appear to be excessively large and some excessively small, relative to the sizes of the entire models of which they are a part. Some external models contain many real-time analog and status measurements, and some have few or none.

Based on these observations, RTBPTF recommends that a task force be created to focus specifically on external models used to support real-time applications. This task force would be charged with defining guidelines and/or minimum requirements related to external modeling. The areas addressed should include, but are not be limited to:

- The level of external model detail needed to support accurate real-time contingency analysis solutions
- Methods for determining which buses, branches, and other elements to include in an external model for a given internal model
- Methods for determining the real-time analog and status measurements to be included in the external model (i.e., the level of measurement observability)
- Methods for exchanging modeling data and the data-exchange format(s) to use. This includes network model and other supporting information (e.g., station one-line diagrams)
- Methods for maintaining and updating external models
- Identification of tools needed to create and maintain an external model (CIM XML editing tools, model merge tools, reduction/equivalencing tools, etc.).

CIM XML Model Exchange

Based on the Real-time Tools Survey responses and supplemental information collected in follow-up discussions with selected respondents, it appears that some technical issues need to be resolved before the use of power system modeling data contained in CIM XML files becomes commonplace. To date, the few entities that have used CIM XML model dumps in their maintenance activities report in follow-up comments that they have found it to be a challenging exercise. Some current technical issues include:

- Problems are caused by different EMS vendor interpretations of the CIM standard.

- Vendor tools are not always compatible with the exact version of CIM used to create a source model.
- CIM XML files are generally very large. These large files sometimes stress (and sometimes break) the tools that are used to manipulate them.
- Resolving data issues by browsing XML files is difficult because these files cannot easily be read, unlike other model formats such as PSS/E, simple flat files, etc.
- Support tools to manipulate CIM models (e.g., network reduction utilities) are lacking. This is important because most users will not want to incorporate an entire model they receive from another entity (e.g., they may want to strip out the lower voltages).

Despite these and other problems, it is generally believed that CIM XML files will eventually be the preferred format for exchanging power system model data once the major technical issues are addressed.

RTBPTF recommends a review of the current state of CIM XML model exchange to determine in detail where and how this format is being used, identify known problems, and make recommendations about how the industry should proceed with CIM XML model exchange. Short-term model data exchange solutions to use in the interim should also be investigated and identified.

Recommendations for Operating Guidelines

RTBPTF does not recommend developing operating guidelines related to modeling practices and tools.

Areas Requiring More Analysis

RTBPTF identified no areas requiring additional analysis for modeling practices and tools.

Examples of Excellence

RTBPTF identified no examples of excellence related to modeling practices and tools.

Section 5.0
Support and Maintenance Tools

Introduction

RTBPTF believes that tools and applications for support and maintenance of real-time tools help enhance operator situational awareness. If real-time tools are not supported and maintained, performance measures such as application availability, data integrity, and application solution quality can be compromised without operators knowing. In addition, the equipment (i.e., servers, data links) needed to run real-time tools should be monitored and maintained to preserve the integrity and availability of the real-time tools.

Proper support and maintenance require that support and maintenance personnel have access to the tools/applications that keep real-time tools running. These are also the tools/applications that inform the operator of the availability status of essential real-time tools and thereby contribute to operator situational awareness.

RTBPTF analyzed five support and maintenance tools: display maintenance tools, change management tools and practices, facilities monitoring tools, critical applications monitoring tools, and trouble reporting tools. RTBPTF's analysis and recommendations for each of these tools are presented in Sections 5.1 through 5.5.

Section 5.1, Display Maintenance Tool — A tool/application used by support personnel to develop and maintain power system displays used by operators to monitor, assess, or perform the actions necessary to maintain the reliability of the bulk electric system. Power system displays enhance operator situational awareness.

Section 5.2, Change Management Tools and Practices — Tools/applications used by support personnel to maintain, modify, and/or test critical equipment and/or critical real-time tools[1] that operators use to monitor, assess, or perform the actions necessary to maintain the reliability of the bulk electric system. The practices and processes of support personnel are also discussed this section.

Section 5.3, Facilities Monitoring — Tool/applications that monitor the status of computer systems equipment, servers, backup systems, communications systems, networks, and other critical facilities, etc. This tool allows operators and support personnel to maintain awareness of critical equipment issues that may affect the availability of critical real-time tools used to operate and monitor the bulk electric system.

Section 5.4, Critical Applications Monitoring — Tools/applications that monitor the status of critical real-time tools. These tools allow operators and support personnel to maintain awareness of the availability status of critical real-time tools. Critical real-time tools must be available for operators to monitor, assess, and perform the necessary actions necessary to maintain the reliability of the bulk electric system.

---

[1] See the Terminology subsection below for an explanation of the terms "critical equipment" and "critical real-time tools."

Section 5.5, Trouble-Reporting Tool — An application that allows control center tool users (i.e. operators and support personnel) to enter trouble reports (e.g., application problems, system problems, display problems, etc.) so that problems and their resolutions are documented and tracked.

Terminology

RTBPTF introduces two new terms in Section 5 to facilitate discussions and recommendations. The new terms are built on current definitions approved in the NERC Cyber Security Standards, CIP-002 through CIP-009, which were developed by the electric industry to improve the security of cyber assets critical to the reliable operation of the North American bulk electric system. The standards were approved by the NERC BOT on May 2, 2006, and became effective on June 1, 2006. The Cyber Security Standards define the following terms:

- Critical Assets — Facilities, systems, and equipment which, if destroyed, degraded, or otherwise rendered unavailable, would affect the reliability or operability of the bulk electric system.
- Cyber Assets — Programmable electronic devices and communication networks including hardware, software, and data.
- Critical Cyber Assets — Cyber assets essential to the reliable operation of critical assets.

RTBPTF introduces the following terms:

- Critical Equipment — Installed equipment that makes up the communication networks, data links, and computer equipment that are directly used as the computer infrastructure for critical real-time tools (see definition below). Critical equipment is essential for reliability entities to ensure the reliable operation of the bulk electric system. Critical equipment is a subset of critical cyber assets (i.e., not all critical cyber assets are considered critical equipment; critical equipment is critical cyber assets that are directly used as the computer infrastructure for critical real-time tools).
- Critical Real-Time Tool — Installed software that is essential (and mandatory) to support, operate, or otherwise interact with bulk electric system operations. Critical real-time tools do not include process control applications or distributed control system applications installed in generating stations, switching stations, or substations.

Significance to the August 14, 2003 Blackout

The support and maintenance tools discussed in this report address some of the issues identified by the August 14, 2003 blackout investigation. Change management tools, facilities monitoring applications, and critical applications monitoring tools enhance operator and support personnel situational awareness. Many of the recommendations for adding new requirements to the existing NERC reliability standards that are presented in the following sections of Chapter 5 relate to these three support and maintenance tools/applications.

The display maintenance tool does not directly support situational awareness; however, it is essential to the creation of power system displays, which are used by operators to enhance their situational awareness. The trouble reporting tool can be used as part of a change management tool to track and document application, system, and display problems and the resolution of each problem. Improper use of each of these tools was cited as a contributing factor to the August 14, 2003 blackout.

Processes for Interactions between Support Personnel and Operators

The lack of situational awareness caused by the failure of support personnel to have or use proper change management tools and practices played a role in the August 14, 2003 blackout. Two failures of this type were identified.

The first failure is identified in a report by the NERC Steering Group (2004):

> FE control center computer support staff did not fully test the functionality of applications, including the alarm processor, after a server failover and restore. After the FE computer support staff conducted a warm reboot of the energy management system to get the failed servers operating again, they did not conduct a sufficiently rigorous test of critical energy management system applications to determine that the alarm processor failure still existed. Full testing of all critical energy management functions after restoring the servers would have detected the alarm processor failure as early as 15:08 and would have cued the FE system operators to use an alternate means to monitor system conditions. Knowledge that the alarm processor was still failed after the server was restored would have enabled FE operators to proactively monitor system conditions, become aware of the line outages occurring on the system, and act on operational information that was received. Knowledge of the alarm processor failure would also have allowed FE operators to warn MISO and neighboring systems, assuming there was a procedure to do so, of the loss of a critical monitoring function in the FE control center computers, putting them on alert to more closely monitor conditions on the FE system.[2]

Because of this deficiency, NERC directed FE to "develop and implement a written procedure describing the interactions between control center technical support personnel and system operators. The procedure shall address notification of loss of critical functionality and testing procedures.[3]" Change management tools and practices would have aided FE in managing this type of support and maintenance issue with its critical reliability tools. A "sufficiently rigorous test" for critical equipment and critical reliability tools is necessary when changes/modifications occur to ascertain the integrity of critical infrastructure and the tools and applications used to maintain the reliability of the bulk electric system.

The second failure was when MISO support personnel analyzed the unacceptably large mismatch produced by its state estimator. The NERC Steering Group report (2004)

---

[2] Technical Analysis of the August 14, 2003, Blackout: *What Happened, Why, and What Did We Learn?* 2004. Report to the NERC Board of Trustees by the NERC Steering Group. July 13. p. 96.
[3] Ibid., p. 118.

states, "... the first sign of trouble came at 12:15, when MISO's state estimator experienced an unacceptably large mismatch error between state-estimated values and measured values. The error was traced to an outage of Cinergy's Bloomington-Denois Creek 230-kV line that was not updated in MISO's state estimator. The line status was quickly corrected, but the MISO analyst forgot to reset the state estimator to run automatically every five minutes.[4]" Without proper change management tools and practices, an error such as this failure to reset a critical real-time tool and verify the integrity of the tool with operators, is more likely to occur. Errors of this type can compromise bulk electric system reliability.

As a result of the above deficiency, NERC directed MISO to "reevaluate and improve its communications protocols and procedures with operational support personnel within MISO…[5]" Change management tools and practices would have aided MISO in managing this type of support and maintenance issue with at least one of its critical reliability tools.

Section 5.1 discusses change management tools and practices, and Section 5.5 discusses trouble reporting tools, which can also be viewed as change management tools. The relationship between the two sections is the strong methodology for tying support personnel actions related to critical equipment and critical real-time tools to operator situational awareness; that is, both tools provide a means to communicate to operators any changes made to critical equipment and critical real-time tools, which enhances situational awareness.

Critical Equipment and Critical Real-Time Tools Monitoring

The ability to maintain operator situational awareness of the status of critical equipment and critical real-time tools is an essential component of reliability. NERC Steering Group analysis of the 2003 blackout (2004) states:

> …shortly after 14:14, the alarm and logging system in the FE control room failed and was not restored until after the blackout. Loss of this critical control center function was a key factor in the loss of situational awareness of system conditions by the FE operators. Unknown to the operators, the alarm application failure eventually spread to a failure of multiple energy management system servers and remote consoles, substantially degrading the capability of the operators to effectively monitor and control the FE system...[6]

The document further states that:

> … at 14:41, the primary server hosting the [FE] EMS alarm processing application failed, due either to the stalling of the alarm application, the "queuing" to the remote terminals, or some combination of the two. Following pre-programmed instructions, the alarm system application and all other EMS

[4] Technical Analysis of the August 14, 2003, Blackout: *What Happened, Why, and What Did We Learn?* 2004. Report to the NERC Board of Trustees by the NERC Steering Group. July 13. p. 28.
[5] Ibid, p. 118.
[6] Ibid, p. 27.

software running on the first server automatically transferred ("failed-over") onto the back-up server. However, because the alarm application moved intact onto the back-up while still stalled and ineffective, the back-up server failed 13 minutes later, at 14:54. Accordingly, all of the EMS applications on these two servers stopped running… The concurrent loss of two EMS servers apparently caused several new problems for the FE EMS and the system operators using it… although the FE computer support staff should have been aware that concurrent loss of its servers would mean the loss of alarm processing on the EMS, the investigation team has found no indication that the IT staff informed the control room staff either when they began work on the servers at 14:54 or when they completed the primary server restart at 15:08. At 15:42, a member of the computer support staff was told of the alarm problem by a control room operator. FE has stated to investigators that their computer support staff had been unaware before then that the alarm processing sub-system of the EMS was not working.[7]

The above excerpts illustrate the importance of operator and support personnel awareness of the availability status of critical equipment and critical real-time tools. Unavailability of critical equipment and critical real-time tools compromises the reliability of the bulk electric system. In addition, unavailability of critical equipment and critical real-time tools hinders operators' ability to maintain situational awareness.

RTBPTF Recommendations for New Reliability Standards

The NERC Cyber Security Standards address many of the issues related to critical cyber asset security that were identified by the August 14, 2003 blackout investigation. The Cyber Security Standards require that tools and processes be established to ensure that at least minimum security controls are in place to protect critical equipment. However, RTBPTF believes that the Cyber Security Standards do not sufficiently ensure operator situational awareness (i.e., RTBPTF believes that operators must be required to know the availability status of critical equipment and critical real-time tools because these tools are essential to the reliable operation of the bulk electric system).

In the sections that follow, RTBPTF makes several recommendations for modifying the requirements of NERC standard IRO-005. RTBPTF also recommends the development of three operating guidelines and identifies one area requiring additional analysis to support the recommended changes to IRO-005. In addition, the task force identifies eight entities whose use of support and maintenance tools can be considered examples of excellence within the industry.

Specifically, RTBPTF recommends that:

- Each RC and TOP be required to identify critical equipment (in a Critical Equipment Identification Document) that it uses to monitor the bulk electric system and maintain awareness of critical equipment status to ensure that

---

[7] Page 33-34 of the "Technical Analysis of the August 14, 2003, Blackout: What Happened, Why, and What Did We Learn?" document

unavailability of critical equipment does not impair the reliable operation of the bulk electric system.

- Each RC and TOP be required to include, at a minimum,
    - The following list of critical real-time tools used in the operation and monitoring of the bulk electric system: alarm tools, telemetry data systems (including applications for SCADA and ICCP Data Link telemetry data), state estimator, network topology processor, and contingency analysis.
    - The following list of critical equipment used in the operation and monitoring of the bulk electric system: servers or computers that contain the critical real-time tools specified above and the data links that provide the input to the critical real-time tools specified above.
- Each RC and TOP be required to maintain a Critical Equipment Monitoring Document identifying its tools and procedures for monitoring critical equipment (including critical real-time applications) and notifying operators when critical equipment is unavailable.
- Each RC and TOP be required to implement automated tools or organizational processes to monitor critical equipment (which includes critical real-time applications) and related system events to ensure reliable operation of the bulk electric system.
- Each RC and TOP be required to maintain event logs pertaining to critical equipment (which includes critical real-time applications) status for a period of one year.
- Each RC and TOP be required to maintain a Critical Equipment Maintenance and Testing Document identifying its tools and procedures for maintenance, modification, and testing of critical equipment.

RTBPTF also proposes measures for the requirements recommended for Standard IRO-005-1.

Section 5.1
Display Maintenance Tool

Definition

Support personnel use the display maintenance tool to develop and maintain visual interfaces that operators use to maintain situational awareness, i.e., to monitor and assess bulk electric system reliability and/or take action to maintain system reliability.

Background

Displays are human-machine interface (HMI) views that allow operators to monitor, assess, or perform necessary actions to maintain the reliability of the bulk electric system during normal and emergency operations. Displays usually present visual representations of power system elements and other application data; this information is the basis for operator situational awareness. Although not a real-time tool, the display maintenance tool is critical for support personnel to keep visual interfaces operational.

Summary of Findings

The majority (96 percent) of respondents to the display maintenance tool section of the Real-Time Tools Survey have an operational display maintenance tool that offers the functionality defined in the survey. The overwhelming majority (94 percent) of all respondents that have an operational display maintenance tool rated it "essential" for situational awareness. Not one entity rated the application as of "minimal" or of "no value." One respondent notes that "without a display maintenance tool, there would be no way to build supporting displays." Table 5.1-1 shows the breakdown of the ratings.

NOTE: In the columns of all tables in this section that list percentages of respondents, the percentage value is preceded by the number of respondents out of the total that gave the indicated response. For example, "32/38=84%" means that 32 out of a total of 38 respondents, or 84% of respondents, gave the indicated response.

Respondent Type	How do you Rate the Value of Your Display Maintenance Tool as a Critical Support Tool to Enhance Reliability Operation and Situational Awareness?	
	"Essential"	"Desirable"
All	29/31=94%	2/31=6%
RC	13/13=100%	0/0=0%
Others	16/18=89%	2/18=11%

Table 5.1-1 — Value of Display Maintenance Tool

Although respondents consistently rate the application as an essential support tool, they report significant variation in its implementation and usage.

Power System Displays

Most power system displays built for operators present SCADA measurements/telemetry data from the field. Most respondents indicate that they use power system displays that contain the state estimator or operator power-flow application solution (see Table 5.1-2). This is common industry practice: to leverage display of SCADA measurements to represent equivalent state estimator or operator power-flow solutions. Some entities use the same power system representation for their DTS application as well as their outage scheduler application. The most widely used types of power system displays are:

- One-Line Displays — visually represent a substation (transmission or distribution) and its corresponding power system elements. Discussed extensively in Section 2.2, Visualization Techniques.
- Transmission-Line Circuit Displays — visually represent the circuit connectivity of transmission substations to adjacent transmission substations; the distribution substations between two transmission substations are also often represented.
- Transmission Overview Displays — show a wide-area view of a transmission grid. Could also be referred to as dynamic overview displays or wide-area visualization displays (depending on usage). Discussed extensively in Section 2.2, Visualization Techniques.

One-Line Displays			
Type	**All**	**RC**	**Others**
SCADA	31//31=100%	12/12=100%	19/19=100%
State Estimator	27/31=87%	12/12=100%	15/19=79%
Power Flow	27/31=87%	12/12=100%	15/19=79%
DTS	17/31=55%	8/12=67%	9/19=47%
Outage Scheduler	3/31=10%	1/12=8%	2/19=10%
Transmission-Line Circuit Displays			
Type	**All**	**RC**	**Others**
SCADA	25/29=86%	10/12=83%	15/19=79%
State Estimator	26/29=90%	11/12=92%	15/19=79%
Power Flow	25/29=86%	10/12=83%	15/19=79%
DTS	14/29=48%	7/12=58%	7/19=37%
Outage Scheduler	3/29=10%	1/12=8%	2/19=10%
Transmission Overview Displays			
Type	**All**	**RC**	**Others**
SCADA	28/31=90%	11/12=92%	17/19=89%
State Estimator	22/31=71%	9/12=75%	13/19=68%
Power Flow	21/31=68%	9/12=75%	12/19=63%
DTS	14/31=45%	6/12=50%	8/19=42%
Outage Scheduler	2/31=6%	1/12=8%	1/19=5%

Table 5.1-2 — Power System Displays

Display Validation

Power system displays are critical visual representations of the monitored electric system, so the accuracy of display information is of great importance. The Real-Time Tools Survey asked respondents for a free-form description of the methods used to validate their displays. Respondents described the following methods:

- Display Testing — Displays are tested initially from a development system before being loaded into the operational system. Validation includes error checking and functional testing to ensure that displays will not harm the operational system. Links between displays and operational data are checked to be sure they are accurate and working correctly.
- Data Accuracy Checks — Despite a wide range of tools available for checking display problems, display accuracy is commonly checked manually by comparison to paper diagrams.

Noteworthy Functional Features

The survey results reveal that display maintenance tools are widely used and considered essential. The survey did not quantify their effectiveness; however, it is clear that accurate displays and detection of display errors enhance situational awareness. Many entities use multiple tools and practices to support display maintenance for various applications and systems, including wide-area overview displays and mapboards. RTBPTF believes these findings could help entities improve and benchmark their current display maintenance processes through self assessment. The following is a list of functional features deemed “essential” (based on ratings by a significant majority of survey respondents) to enhance situational awareness:

- Automatic Display Generator for Power System Displays — Enable an application to automatically generate power system displays from a single display. For example, from a SCADA station one-line display, the state estimator, power flow, etc. station one-line displays can be generated. Without this feature, support personnel would have to manually create the other power system displays. Manually creating displays could introduce errors and inconsistency; creating similar displays using a program could mitigate this problem. Forty-nine percent of respondents have an operational version of this feature. Of the entities that have this operational feature, 71 percent rate it “essential,” 14 percent as “desirable,” and 14 percent as of “minimal value” for situational awareness.
- Bad Display Link Indicator — Allows an application to automatically generate a summary of incorrect display linkages for telemetered data for multiple displays that use a given link. This feature signifies that the data being presented may be inaccurate. Forty-one percent of survey respondents have an operational version of this feature. Of the entities that have this feature operational, 92 percent rate it as “essential,” and 8 percent rate it as “desirable” for situational awareness.

Recommendations for New Reliability Standards

RCs, TOPs, and BAs depend on the availability and accuracy of displays to operate the bulk electric system in a coordinated manner so that it performs reliably under normal and abnormal conditions, as defined in NERC standards. The Real-Time Tools Survey responses reveal significant variation in display maintenance practices; the industry as a whole has no cohesive method of maintaining displays for operator use. The display maintenance tool indirectly affects bulk electric system reliability, but the availability and accuracy of the displays designed and created using this tool directly affects system reliability. These displays are discussed in Section 2.2, Visualization Techniques. RTBPTF has no recommendations for new reliability standards for the display maintenance tool.

Recommendations for Operating Guidelines

Because RTBPTF recommends no reliability standards related to display maintenance tools, it also has no recommendations for operating guidelines.

Areas Requiring More Analysis

RTBPTF identified no areas requiring additional analysis for display maintenance tools.

Examples of Excellence

RTBPTF cites the California Mexico RC's use of a display maintenance tool application to ensure that its energy management system displays are functioning properly as an example of excellence (See EOE-17 in Appendix E).

Section 5.2
Change Management Tools and Practices

Definition

Support personnel use change management tools and practices to maintain, modify, and/or test critical equipment[8] that operators use to monitor and perform necessary actions to maintain reliability of the bulk electric system.

Background

The availability and integrity of critical equipment in control centers directly affect reliability. Therefore, the tools and practices used to maintain, modify, and test critical equipment — usually called change management tools and practices – are directly related to reliability. Support personnel must use proper change management tools and practices to avoid disruptions in the function or availability of critical equipment that could affect operators' situational awareness.

The *Outage Task Force Final Blackout Report* notes that, as part of the events related to the August 2003 blackout, FE support personnel rebooted servers that had a failed alarm module without checking with control room staff/operators to confirm that all applications were running properly. In another event related to the blackout, MISO support personnel left software in a manual operation mode after solving a state estimator mismatch. These two examples signify a deficiency in change management tools and practices. On each occasion, the problem could have been averted if proper maintenance and testing procedures had been in place. In FE's case, effective change management tools and practices would have required that personnel check with the operators to find out whether the alarm tools application problem was resolved after the module reboot. In MISO's case, effective change management tools and practices would have required verification that the state estimator was running in a condition that allowed the operator to use it, so the application would not have been left in manual mode.

In short, failure of support personnel to use appropriate change management tools and practices played a role in the August 14, 2003 blackout. Causal analysis in the *Outage Task Force Final Blackout Report* reveals the following deficiencies:

> Cause 1c: FirstEnergy control center computer support staff did not fully test the functionality of applications, including the alarm processor, after a server failover and restore.

---

[8] For the purposes of this discussion, *critical equipment* is defined as installed equipment that makes up infrastructure and systems (including communication networks, data links, hardware, software applications, and data bases) that are directly used as critical real-time tools. Critical equipment is a subset of critical cyber assets. *Critical real-time tools* are defined as installed software that is essential to support, operate, or otherwise interact with bulk electric system operations. All reliability entities (not just RCs) need critical equipment and real-time tools to ensure reliable operation of the bulk electric system.

The Corrective Actions section of the *Outage Task Force Final Blackout Report* recommends:

g. Technical Support. FirstEnergy shall develop and implement a written procedure describing the interactions between control center technical support personnel and system operators. The procedure shall address notification of testing procedures and loss of critical functionality.[9]

Summary of Findings

The Real-time Tools Best Practices Survey was designed to examine current tools and practices in software (rather than hardware) maintenance, modification, and testing. Most survey respondents (78 percent) have operational software maintenance tools. They also indicate that they have maintenance, modification, and testing practices. The majority (77 percent) of all respondents that have operational software maintenance tools rate these tools as “essential” for situational awareness; a minority (23 percent) rate their tools “desirable” for situational awareness. Not one entity rates its tools as of “minimal value” or “no value” for situational awareness. One respondent states that “it is essential for support personnel to have a quick method to access the source code of critical/core applications in case there is an issue that requires code repairs. This access needs to be controlled so that the operational environment is not affected when code is compiled and loaded into the operational system.” This majority percentage was consistent across all entity types except BAs (see Table 5.2-1).

Entity Type	How do You Rate the Value of Your Software Maintenance Tools and Practices as a Critical Support Tool to Enhance Reliability Operation and Situational Awareness?	
	“Essential”	**“Desirable”**
All	27/35=77%	8/35=23%
RCs	12/16=77%	4/16=23%
Others	15/19=79%	4/19=21%

Table 5.2-1 — Value of Software Maintenance Tools

The survey results also reveal that most entities (97 percent) that have operational software maintenance tools also have source codes on hand for their reliability tools/applications. Most entities (91 percent) indicate that their support staff can modify (when necessary) the source codes of their reliability tools/applications.

[9] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April.

Practices/Processes Related to Software Maintenance Tools

Most entities (85 percent) that have operational software maintenance tools have some form of code control process, i.e., a software (source code) change management process, such as version control, change tracking, or user management and administration. The majority of entities (81 percent) that have this process/tool available rate it "essential" for enhancing situational awareness.

Most entities (76 percent) that have operational software maintenance tools do not have the ability to notify (via paging) software support personnel if new software is loaded on-line. This question was included in the survey because RTBPTF believes this type of notification enhances situational awareness of support personnel when certain applications are being updated online.

Recommendations for New Reliability Standards

To ensure proper maintenance, modification, and testing, RTBPTF recommends that new requirements for change management tools and practices be added to existing standard IRO-005 (Reliability Coordination – Current Day Operations) to strengthen operator situational awareness. RTBPTF recommends adding the change management requirements to the reliability coordination current day operations standard rather than the cyber security standards because the latter focus primarily on protecting and securing critical cyber assets; specifically, Standard CIP-003 requires that responsible entities have minimum security management controls in place to protect critical cyber assets. The cyber security standards do not, however, explicitly address operator situational awareness of critical equipment that may affect the reliable operation of the bulk electric system.

Change management requirements could, in principle, also be added to NERC's cyber security standards CIP-002 through CIP-009, which specifically address change control and configuration management for software and hardware maintenance. Standard CIP-003 (Cyber Security – Security Management Controls), Requirement 6, states that "the Responsible Entity shall establish and document a process of change control and configuration management for adding, modifying, replacing, or removing Critical Cyber Asset hardware or software, and implement supporting configuration management activities to identify, control, and document all entity or vendor-related changes to hardware and software components of Critical Cyber Assets pursuant to the change control process." The cyber security standards require that tools and processes be established so that minimum security controls are in place to protect critical equipment.

However, RTBPTF recommends adding the change management requirements to Standard IRO-005 because operator awareness of the status of critical equipment (which is directly related to critical equipment maintenance, modification, and testing processes) is essential to the RC's continuous awareness of conditions that may impair the operator's ability to operate the bulk electric system reliably. RTBPTF recommends that a new requirement be added to IRO-005 to require RCs and TOPs to implement automated tools or organizational processes to monitor critical equipment availability, including the activities related to critical equipment maintenance, modification, and testing.

RTBPTF Recommendation

The requirements recommended for addition to existing Standard IRO-005 are stated below.[10] The full text of interrelated requirements applicable to critical equipment, which comprises three areas, (change management tools and practices, facilities monitoring (Section 5.3), and critical applications monitoring (Section 5.4)) is presented here for clarity. The requirements related to the topic of this section of the report, change management tools and practices, are highlighted in italic font.

PR1. Each reliability coordinator and transmission operator shall monitor and maintain awareness of critical equipment status to ensure that the unavailability of critical equipment does not impair the reliable operation of the bulk electric system. Other entities supporting or complementing the reliability coordinator's or transmission operator's ability to operate the bulk electric system reliably shall be subject to the same requirements as the reliability coordinator or transmission operator respectively.

PR1.1. Identification of critical equipment — Each reliability coordinator and transmission operator shall identify the critical equipment it uses for bulk electric system operation and monitoring. This includes the critical equipment of parties to whom the reliability coordinator or transmission operator has delegated reliability functions. Each reliability coordinator and transmission operator shall maintain a Critical Equipment Identification Document that lists all critical equipment. The Critical Equipment Identification Document shall be kept current at all times.

PR1.1.1. Each reliability coordinator and transmission operator shall include, at a minimum, the following list of critical real-time tools used in the operation and monitoring of the bulk electric system: alarm tools, telemetry data systems (includes applications for SCADA and ICCP Data Link telemetry data), state estimator, network topology processor, and contingency analysis.

PR1.1.2. Each reliability coordinator and transmission operator shall include, at a minimum, the following list of critical equipment used in the operation and monitoring of the bulk electric system: servers or computers that contain the critical real-time tools specified above and the data links that provide the input to the critical real-time tools specified above.

[10] Proposed requirements are designated "PR," and proposed measures are designated "PM."

Recommendation – S37

Maintain a Critical Equipment Monitoring Document to identify tools and procedures for monitoring critical equipment.

PR1.2. *Monitoring of Critical Equipment — Each reliability coordinator and transmission operator shall maintain a Critical Equipment Monitoring Document identifying its tools and procedures for monitoring critical equipment (which includes critical real-time applications). This document shall describe how to verify that the tools and procedures are functioning and being used as intended. This document shall describe the tools and procedures for operator notification when critical equipment is unavailable*.

PR1.2.1. *Each reliability coordinator and transmission operator shall implement automated tools or organizational processes to monitor critical equipment (which includes critical real-time applications) and related system events to ensure reliable operation of the bulk electric system. These tools or organizational processes shall be described in the Critical Equipment Monitoring Document.*

Recommendation – S38

Maintain event logs pertaining to critical equipment status for a period of one year.

PR1.3. *Each reliability coordinator and transmission operator shall maintain event logs pertaining to critical equipment (which includes critical real-time applications) status for a period of one year. At a minimum, the event logs shall contain the following information regarding any event that affects the functionality and/or availability of critical equipment. The event log shall address the following questions: What happened? When did it happen? Who was notified? What was the resolution?*

Recommendation – S39

Maintain a Critical Equipment Maintenance and Testing Document identifying tools and procedures for maintenance, modification, and testing of critical equipment.

PR1.4. *Maintenance of Critical Equipment — Each reliability coordinator and transmission operator shall maintain a Critical Equipment Maintenance and Testing Document identifying its tools and procedures for maintenance, modification, and testing of critical equipment. This document shall describe how to verify that the tools and procedures are functioning and being used as intended*.

RTBPTF recommends the following measures for the requirements stated above. The measures related to change management tools and practices are written in italic font.

PM 1. Measures for Critical Equipment Monitoring

PM 1.1 The Critical Equipment Identification Document must be available as specified in Requirement PR1.1. Additionally, each reliability coordinator and transmission operator shall demonstrate that the Critical Equipment Identification Document is kept current at all times.

PM 1.1.1. As specified in Requirement PR1.1.1, the Critical Equipment Identification Document must contain, as part of its list of critical real-time applications, the following applications: alarm tools, telemetry data systems (includes applications for SCADA and ICCP Data Link telemetry data), state estimator, network topology processor, and contingency analysis.

PM 1.1.2. As specified in Requirement PR1.1.2, the Critical Equipment Identification Document must contain, as part of its list of critical equipment, the following equipment: servers or computers that contain the critical real-time tools, and the data links that provide the input to the critical real-time tools specified.

PM 1.2 *The Critical Equipment Monitoring Document must be available as specified in PR1.2. Additionally, each reliability coordinator and transmission operator must demonstrate that the Critical Equipment Monitoring Document is kept current at all times and that the documented tools/procedures are used as intended*.

PM 1.2.1. *Each reliability coordinator and transmission operator must demonstrate, upon request, its capability to monitor critical equipment via automated tools (e.g., critical equipment status displays or visualization tools) or organizational processes (e.g., trouble* *notification processes) as stated in Requirement PR1.2.1.*

PM 1.3 *Each reliability coordinator and transmission operator must demonstrate that the event logs as stated in Requirement PR1.3 contain the required information*.

PM 1.4 *The Critical Equipment Maintenance and Testing Document must be available as specified in PR1.4.*

Rationale

The "Purpose" section of Standard IRO-005 states, "The Reliability Coordinator must be continuously aware of conditions within its Reliability Coordinator Area and include this information in its reliability assessments. The Reliability Coordinator must monitor Bulk Electric System parameters that may have significant impacts upon the Reliability Coordinator Area and neighboring Reliability Coordinator Areas." RTBPTF believes that operator awareness of the status of critical equipment (which is directly related to critical equipment maintenance, modification, and testing processes) is essential to the reliability coordinator's continuous awareness of conditions that may impair the operator's ability to operate the bulk electric system reliably. Therefore, the change management requirements for critical equipment maintenance, modification, and testing should be included as part of this standard. Other entities supporting or complementing the RC's ability to operate the bulk electric system reliably must be subject to the same requirements as the RC. As noted in the Summary of Findings section above, the *Outage Task Force Final Blackout Report* notes that the lack of strong change management tools and practices contributed to the lack of operator situational awareness related to the August 2003 blackout*.*

RTBPTF includes TOPs in the recommendations stated above because these entities are subject to the Reliability Toolbox requirement.[11]

Recommendations for Operating Guidelines

RTBPTF recommends development of the following operating guidelines for change management tools and practices. These operating guidelines support the recommended additional requirements to Standard IRO-005-1 stated above.

- Each reliability coordinator should have a demonstrated change management process for performing critical equipment maintenance, modification, and testing. This change management process should have the objective/purpose of ensuring the availability and integrity of critical equipment. The change management process should, at a minimum, include the following:
    - Management, operator, and support personnel notification and approval for production system changes
    - Pre- and post-production testing of system installation testing

[11] See the Reliability Tool Box Rationale and Recommendation section as well as the specific recommendations for each tool in the Reliability Toolbox.

    - Personnel authorization and security
    - System source code backup and recovery
- Each reliability coordinator should have a change management tool that has, at a minimum, the following capabilities:
    - Audit logging of all activities (modifications, additions, deletions, etc.) related to all source code files
    - Version control with the ability to roll back to an earlier version

Areas Requiring More Analysis

RTBPTF identified no areas requiring additional analysis for change management tools and practices.

Examples of Excellence

RTBPTF cites PJM's use of a feature management system that provides audit logging and version control capabilities as an example of excellence (See EOE-18 in Appendix E). The approach taken by PJM ensures that software modifications do not compromise the availability and integrity of their critical real-time applications that support operator situational awareness

Section 5.3
Facilities Monitoring

Definition

The facilities monitoring application tracks the status of computer systems equipment, servers, backup systems, communications systems, networks and other critical facilities. This tool allows operators and/or support personnel to be aware of critical equipment issues that may affect the availability of critical real-time tools used to operate and monitor the bulk electric system.

Background

As discussed in detail in Section 5.0, Support and Maintenance Tools, situational awareness of the status of critical equipment, which includes facilities such as computer systems equipment, servers, backup systems, communications systems, networks and other critical facilities in the control center, is an essential component directly related to reliability. The *Outage Task Force Final Blackout Report* states that FE's operators were unaware of the failure and the concurrent loss of two EMS servers that apparently caused several new problems for the FE EMS and the operators using it. This illustrates the importance of having monitoring tools that report unavailability of critical equipment. Operators need to be aware when their ability to monitor the bulk electric system is compromised. Proper notification of maintenance and support personnel is requisite for real-time operations.

The operator has to have keen awareness of the status and availability of critical equipment. This includes critical equipment that is used as a backup to primary critical equipment. The operator could have no provision for monitoring the bulk electric system if a critical piece of equipment is unavailable or not working correctly. Critical real-time tools depend on critical equipment, and a facilities monitoring application allows for operators to be aware of the status and availability of critical equipment, which enhances operator situational awareness.

Summary of Findings

The majority of respondents (86 percent) have an operational facility monitoring application that offers the same functionality as defined in the Real-Time Tools Survey. Interestingly, all RCs report having an operational facilities monitoring application. For respondents that have an operational facilities monitor, the majority (84 percent) rate this application "essential" for situational awareness while 16 percent rate it "desirable." Not one entity rates the application as of "minimal value" or "no value" for situational awareness. One of the respondents states that "any information as to the 'state of the operational system' is a key indicator for situational awareness. For system support personnel, maintaining situational awareness of key infrastructure equipment is analogous to maintaining situational awareness of bulk power system elements." Table 5.3-1 summarizes the survey results.

Entity Type	How do You Rate the Value of Your EMS Facilities Monitor as a Critical Support Tool to Enhance Reliability Operation and Situational Awareness?	
	“Essential”	**“Desirable”**
All	32/38=84%	6/38=16%
RC	13/15=84%	2/15=16%
Others	19/23=83%	4/23=17%

Table 5.3-1 — Value of Facilities Monitor Application

These data suggest that the majority of respondents consider the facilities monitor an essential operational support tool. Because the survey results reveal a significant variation in practice, implementation, and use of this application, it is a logical candidate for some degree of standardization.

The survey asked respondents to identify the types of equipment/facilities that are monitored. A majority of respondents monitor the status of their critical servers, voice/data communication links, internal networks, and backup facilities listed (see Table 5.3-2).

Equipment	All	RC	Others
Status of Critical Servers	38/38=100%	15/15=100%	23/23=100%
Mapboard (Hardware Status) Availability	20/38=53%	11/15=73%	9/23=39%
Voice/Data Communication Links	33/38=87%	13/15=87%	20/23=87%
Internal Communication Network(s)	29/38=76%	12/15=80%	17/23=74%
RTU Status	20/38=79%	11/15=73%	9/23=39%
Availability of Backup System	33/38=87%	13/15=87%	20/23=87%
Power Supply (UPS)	26/38=68%	13/15=87%	13/23=56%
Power Supply (Backup Generators)	24/38=63%	12/15=80%	12/23=52%
Batteries	20/38=53%	10/15=67%	10/23=43%
Heating, ventilation, and air conditioning	15/38=39%	7/15=47%	8/23=35%
Fire Protection Systems	15/38=39%	7/15=47%	8/23=35%

Table 5.3-2 — Equipment/facilities Monitored Using Facilities Monitoring Application, by Entity Type

The survey reveals that entities monitor equipment that is essential to the continuing operation of their control centers. This encouraging result shows that monitoring of critical equipment is a prevailing industry practice. Awareness of critical equipment status supports situational awareness. Critical equipment monitoring tells operators what equipment is available or unavailable, which allows operators to determine whether the capability of these tools is degraded by critical equipment problems.

The survey also examined the functional features of facilities monitoring applications. Ninety-seven percent of respondents report that their facilities monitors interface directly with their alarm tools applications and can generate critical equipment status alarms. Of the entities that use this feature, 86 percent rated it “essential” for situational awareness. These data suggest that an interface between the facilities monitor and the alarm tools enhances situational awareness.

Operators at most entities (87 percent) have access to a visual representation of critical equipment status. Seventy-three percent of entities that have this feature rate it “essential” for situational awareness, 24 percent rate this feature “desirable,” and 3 percent rate it as having “minimal value.” These data suggest that a visual representation of critical equipment status enhances operator situational awareness.

Many entities (56 percent) have a system that pages support personnel when the facilities monitor indicates that a critical equipment status is unavailable. Fifty-five percent of entities that have this functional feature rate it “essential” for situational awareness, 40 percent rate it as “desirable,” and 5 percent rate it as having “minimal value.” These data suggest that an interface between the facilities monitor and a paging system enhances operator situational awareness.

Insufficient data were collected to properly evaluate the usage and implementation of the respondents’ facilities monitor applications. Ideally, to ascertain critical equipment status, the application should be independent of the equipment being monitored. Further exploration is needed to determine whether this strategy is used in the industry. More data are also needed on the methodology used to declare critical equipment “unavailable.”

Recommendations for New Reliability Standards

Because continual monitoring of the availability of critical equipment/critical real-time tools is essential for reliable power system operation, as indicated by the survey results, RTBPTF recommends adding new facilities monitoring requirements to existing standard IRO-005 (Reliability Coordination – Current Day Operations), to strengthen operator situational awareness.

Facilities monitoring requirements could, in principle, also be added to NERC’s cyber security standards CIP-002 through CIP-009, which address securing of critical cyber assets and require that tools and processes be established so that minimum security controls are in place to protect critical equipment. Specifically, Standard CIP-007, Requirement 6 mandates that the responsible entity ensure that all cyber assets within the electronic security perimeter, to the degree technically feasible, implement automated tools or organizational process controls to monitor system events related to cyber security. However, Standard CIP-007 does not explicitly address operator situational awareness of critical equipment that may affect the reliable operation of the bulk electric system; rather it focuses on automated tools or organizational process controls to monitor system events related to cyber security only. Therefore, the RTBPTF recommends adding the facilities monitoring requirements to Standard IRO-005. This standard is a more appropriate location for the requirements because the purpose of IRO-005 is operator awareness of bulk electric system parameters.

RTBPTF Recommendation

The requirements recommended for addition to existing Standard IRO-005 are stated below. The full text of interrelated requirements applicable to critical equipment, which comprises three areas, (change management tools and practices (Section 5.2), facilities monitoring, and critical applications monitoring (Section 5.4)) is presented here for clarity. The requirements related to the topic of this section of the report, facilities monitoring, are highlighted in italic font.

Recommendation – S40

Monitor and maintain awareness of critical equipment status to ensure that lack of availability of critical equipment does not impair reliable operation.

PR1. *Each reliability coordinator and transmission operator shall monitor and maintain awareness of critical equipment status to ensure that the unavailability of critical equipment does not impair the reliable operation of the bulk electric system. Other entities supporting or complementing the reliability coordinator's or transmission operator's ability to operate the bulk electric system reliably shall be subject to the same requirements as the reliability coordinator or transmission operator respectively.*

PR1.1. *Identification of critical equipment — Each reliability coordinator and transmission operator shall identify the critical equipment it uses for bulk electric system operation and monitoring. This includes the critical equipment of parties to whom the reliability coordinator or transmission operator has delegated reliability functions. Each reliability coordinator and transmission operator shall maintain a Critical Equipment Identification Document that lists all critical equipment. The Critical Equipment Identification Document shall be kept current at all times.*

PR1.1.1. Each reliability coordinator and transmission operator shall include, at a minimum, the following list of critical real-time tools used in the operation and monitoring of the bulk electric system: alarm tools, telemetry data systems (includes applications for SCADA and ICCP Data Link telemetry data), state estimator, network topology processor, and contingency analysis.

PR1.1.2. *Each reliability coordinator and transmission operator shall include, at a minimum, the following list of critical equipment used in the operation and monitoring of the bulk electric system: servers or computers that contain the critical real-time tools specified above and* *the data links that provide the input to the critical real-time tools specified above.*

PR1.2. *Monitoring of Critical Equipment — Each reliability coordinator and transmission operator shall maintain a Critical Equipment Monitoring Document identifying its tools and procedures for monitoring critical equipment (which includes critical real-time applications). This document shall describe how to verify that the tools and procedures are functioning and being used as intended. This document shall describe the tools and procedures for operator notification when critical equipment is unavailable.*

PR1.2.1. Each reliability coordinator and transmission operator shall implement automated tools or organizational processes to monitor critical equipment (which includes critical real-time applications) and related system events to ensure reliable operation of the bulk electric system. These tools or organizational processes shall be described in the Critical Equipment Monitoring Document.

PR1.3. Each reliability coordinator and transmission operator shall maintain event logs pertaining to critical equipment (which includes critical real-time applications) status for a period of one year. At a minimum, the event logs shall contain the following information regarding any event that affects the functionality and/or availability of critical equipment. The event log shall address the following questions: What happened? When did it happen? Who was notified? What was the resolution?

PR1.4. Maintenance of Critical Equipment — Each reliability coordinator and transmission operator shall maintain a Critical Equipment Maintenance and Testing Document identifying its tools and procedures for maintenance, modification, and testing of critical equipment. This document shall describe how to verify that the tools and procedures are functioning and being used as intended.

RTBPTF recommends the following measures for the requirements stated above. The measures related to change management tools and practices are written in italic font.

PM 1. *Measures for Critical Equipment Monitoring*

PM 1.1 *The Critical Equipment Identification Document must be available as specified in Requirement PR1.1. Additionally, each reliability coordinator and transmission operator shall demonstrate that the Critical Equipment Identification Document is kept current at all times.*

PM1.1.1. As specified in Requirement PR1.1.1, the Critical Equipment Identification Document must contain, as part of its list of critical real-time applications, the following applications: alarm tools, telemetry data systems (includes applications for SCADA and ICCP Data Link telemetry data), state estimator, network topology processor, and contingency analysis.

PM1.1.2. *As specified in Requirement PR1.1.2, the Critical Equipment Identification Document must contain, as part of its list of critical equipment, the following equipment: servers or computers that contain the critical real-time tools, and the data links that provide the input to the critical real-time tools specified.*

PM 1.2 *The Critical Equipment Monitoring Document must be available as specified in PR1.2. Additionally, each reliability coordinator and transmission operator must demonstrate that the Critical Equipment Monitoring Document is kept current at all times and that the documented tools/procedures are used as intended*.

PM1.2.1. Each reliability coordinator and transmission operator must demonstrate, upon request, its capability to monitor critical equipment via automated tools (e.g., critical equipment status displays or visualization tools) or organizational processes (e.g., trouble notification processes) as stated in Requirement PR1.2.1.

PM 1.3 Each reliability coordinator and transmission operator must demonstrate that the event logs as stated in Requirement PR1.3 contain the required information.

PM 1.4 The Critical Equipment Maintenance and Testing Document must be available as specified in PR1.4.

Rationale

The “Purpose” section of Standard IRO-005 states, “The Reliability Coordinator must be continuously aware of conditions within its Reliability Coordinator Area and include this information in its reliability assessments. The Reliability Coordinator must monitor Bulk Electric System parameters that may have significant impacts upon the Reliability Coordinator Area and neighboring Reliability Coordinator Areas.” RTBPTF believes that information on critical equipment status is essential to the RC’s continuous awareness of conditions that may impair the RC’s ability to operate the bulk electric system reliably. Lack of awareness that critical equipment was unavailable was a significant element contributing to the August 14, 2003 Blackout, as noted in the *Outage Task Force Final Blackout Report*. If a new requirement is not established for monitoring of critical equipment, there will be no way to ensure that operators are aware when critical equipment, such as servers, is unavailable.

RTBPTF included TOPs in the recommendation above because these entities are subject to the recommended Reliability Toolbox requirement and are required to have the critical equipment that provides the infrastructure for the Reliability Toolbox tools.[12]

Recommendation – G13

Establish a change management process for performing critical equipment maintenance, modification, and testing.

Recommendations for Operating Guidelines

RTBPTF recommends development of the following operating guidelines for the facilities monitor application. These operating guidelines support the recommended additional requirements to Standard IRO-005-1 stated above.

Recommendation – G14

Develop a notification process when critical equipment is unavailable and an analysis/resolution process for critical equipment failures.

- Each reliability coordinator should have a demonstrated critical equipment monitoring process. This monitoring process should have the objective/purpose of enhancing operator awareness of the availability of critical equipment. The monitoring process should, at a minimum, include:
    - Notification of management, operator, and support personnel when critical equipment is unavailable
    - An analysis and resolution process for critical equipment failures

[12] See the Reliability Toolbox Rationale and Recommendation section as well as the recommendations for each tool in the Reliability Toolbox.

Recommendation – G15

Develop a critical monitoring application that interfaces to alarm tools and logs all events related to the equipment failures.

- Each reliability coordinator should have a facilities monitoring application, which has, at a minimum, the following capabilities:
  - Interface of facilities monitoring application to alarm tools
  - Audit logging of all events related to critical equipment failures

Areas Requiring More Analysis

RTBPTF identified no areas requiring additional analysis for facilities monitoring.

Examples of Excellence

RTBPTF cites American Electric Power's use of a facilities monitor application by Central and Southwest (CSWS) as an example of excellence (See EOE-19 in Appendix E). CSWS interfaces their facilities monitoring application with their critical applications monitor application.

Section 5.4
Critical Applications Monitoring

Definition

The critical applications monitor tracks the status of critical real-time tools. This application allows operators and/or support group personnel to track availability of critical real-time tools. Critical real-time tools must be available for operators to monitor, assess, and perform the necessary actions to maintain the reliability of interconnected bulk electric systems. A critical applications monitor tool may be part of a facilities monitoring tool (see Section 5.3, Facilities Monitoring).

Background

As discussed in detail in Section 5.0, Support and Maintenance Tools, situational awareness of the status and availability of critical real-time tools is an essential component directly related to reliability. The Outage Task Force Final Blackout Report stated that FE's computer support staff was unaware of the failure of their alarm tools application. FE had no alarm tools failure detection system. When the FE alarm processor stopped functioning properly, computer support staff remained unaware of this failure until a second EMS server failed approximately 40 minutes later. Because FE had no periodic diagnostics to evaluate and report the state of their alarm tools, support staff were not alerted to the eventual failure of two EMS servers or the infinite loop lockup failure of the alarms — or that the alarm processor had failed in this manner earlier and independently of the server failures. This illustrates the importance of having monitoring tools that report unavailability of critical real-time tools. Operators need to be aware when their ability to monitor the bulk electric system has degraded. Proper notification of maintenance and support personnel is requisite for real-time operations.

Summary of Findings

All respondents to the critical applications monitor portion of the Real-Time Tools Survey indicate that they have an operational critical applications monitor tool that offers the same functionality as defined in the survey. Additionally, all respondents rate their critical applications monitor as either "essential" or "desirable" for situational awareness. The majority (88 percent) rate it "essential," and not one entity rates it having "minimal value" or "no value." One respondent states that "this tool has dramatically improved… state estimator availability and…ICCP data availability." This majority rating was consistent across all entity types, as shown in Table 5.4-1.

Entity Type	How do You Rate the Value of Your EMS Critical Applications Monitor as a Critical Support Tool to Enhance Reliability Operation and Situational Awareness?	
	"Essential"	"Desirable"
All	35/40=88%	5/40=12%
RC	13/15=87%	2/15=13%
Others	22/25=88%	3/25=12%

Table 5.4-1 — Value of Critical Applications Monitor, by Entity Type

The survey results reveal that, although the majority of respondents consider the critical applications monitor tool essential, there is a significant variation in practice, implementation, and usage of the tool. Therefore, this tool is a logical candidate for standardization. The survey asked respondents to identify the types of critical applications that are monitored by their organizations. A consistent majority of respondents monitored the critical applications listed in the survey (see Table 5.4-2). Other entities also monitor automatic generation control (AGC) and market applications.

Applications	All	RC	Others
Alarm Tools	36/40=90%	12/15=80%	24/25=96%
State Estimator	28/40=70%	13/15=87%	15/25=60%
Contingency Analysis	25/40=63%	12/15=80%	13/25=52%
SCADA	37/40=93%	13/15=87%	24/25=96%
Inter-Utility Link Data Application	33/40=83%	12/15=80%	21/25=84%

Table 5.4-2 — Applications Tracked by Critical Applications Monitor, by Entity Type

The survey results indicate that the majority of entities have tools and processes to monitor applications that are critical to continuous operation of their control centers. This encouraging result shows that critical applications monitoring is a prevailing industry practice. Critical applications monitoring is important not only for computer support but also for reliable operation of the bulk electric system. Increasing operator awareness of critical real-time tool status increases situational awareness.

The survey also examines the functional features of critical applications monitor applications. All of the respondents can generate alarms based on critical real-time tools status, and the critical applications monitor interfaces directly to the alarm tools application. Of the entities that use this functional feature (interface to alarm tools), 82 percent rate it “essential” for situational awareness. These data suggest that situational awareness is enhanced if the critical applications monitor interfaces with the alarm tools application.

Operators at 72 percent of entities responding to the survey have access to visual representation of critical real-time tools status. Entities that have this functional feature rate it either “essential” (59 percent) or “desirable” (41 percent) for situational awareness. Entities that do not have this feature rate it “desirable” (73 percent) or of “minimal value” (18 percent), or “no value” (9 percent). These results indicate that a majority of the industry believes that visual representation of critical real-time tools status can enhance operator and support staff situational awareness.

Table 5.4-3 shows the percentages of respondents that have a critical applications monitor tool that can page support personnel when a critical real-time application is unavailable or stalled. Entities that have this feature rate it “essential” (56 percent), “desirable” (39 percent), or of “minimal value” (6 percent) for situational awareness. Entities that do not have this feature rate it “desirable” (40 percent), of “minimal value” (50 percent), or of “no value” (10 percent) for situational awareness. Table 5.4-3 shows that the majority of the industry has access to automatic paging from a critical applications monitor although other internal methods of notifying support personnel may be employed.

Response	All	RC	Others
Yes	20/40=50%	11/15=73%	9/25=36%
No	20/40=50%	4/15=27%	16/25=64%

Table 5.4-3 — Entities that Can Page Support Personnel When a Critical Real-time Tool is Unavailable or Stalled, as Determined by the Critical Applications Monitor Tool

The data are insufficient to evaluate the usage and implementation of survey respondents’ critical applications monitor tools. Ideally, to ascertain critical real-time tool status, the monitoring tool should be independent of the critical real-time tool being monitored. For example, if the critical applications monitor tool tracks the alarm tools application, the critical applications monitor tool and the alarm tools application should not reside on the same server. Further investigation is needed to determine whether this scheme is in use in the industry.

Recommendations for New Reliability Standards

Because continual monitoring of the availability of critical equipment/critical real-time tools is essential to for reliable power system operation, as supported by the survey results, RTBPTF recommends adding new critical applications monitoring requirements to existing standard IRO-005 (Reliability Coordination – Current Day Operations), to strengthen operator situational awareness.

Critical applications monitoring requirements could, in principle, also be added to NERC’s cyber security standards CIP-002 through CIP-009, which address securing critical cyber assets and requiring that tools and processes be established so that minimum security controls are in place to protect critical equipment. Specifically, Standard CIP-007, Requirement 6 mandates that responsible entities ensure that all cyber assets within the electronic security perimeter, to the degree technically feasible, implement automated tools or organizational process controls to monitor system events related to cyber security. However, Standard CIP-007 does not explicitly address operator awareness of critical applications that may affect the reliable operation of the bulk electric system; rather, it focuses on automated tools or organizational process controls to monitor system events related to cyber security only. Therefore, RTBPTF recommends adding the critical applications monitoring requirements to Standard IRO-005. This standard is a more appropriate location for the requirements because the purpose of IRO-005-1 is to ensure operator awareness of bulk electric system parameters.

RTBPTF Recommendations

The requirements recommended for addition to existing Standard IRO-005 are stated below. The full text of interrelated requirements applicable to critical equipment, which comprises three areas, (change management tools and practices (Section 5.2), facilities monitoring (Section 5.3), and critical applications monitoring) is presented here for clarity. The requirements related to the topic of this section of the report, critical applications monitoring, are highlighted in italic font:

PR1. *Each reliability coordinator and transmission operator shall monitor and maintain awareness of critical equipment status to ensure that the unavailability of critical equipment does not impair the reliable operation of the bulk electric system. Other entities supporting or complementing the reliability coordinator's or transmission operator's ability to operate the bulk electric system reliably shall be subject to the same requirements as the reliability coordinator or transmission operator respectively.*

PR1.1. *Identification of critical equipment — Each reliability coordinator and transmission operator shall identify the critical equipment it uses for bulk electric system operation and monitoring. This includes the critical equipment of parties to whom the reliability coordinator or transmission operator has delegated reliability functions. Each reliability coordinator and transmission operator shall maintain a Critical Equipment Identification Document that lists all critical equipment. The Critical Equipment Identification Document shall be kept current at all times.*

PR1.1.1. *Each reliability coordinator and transmission operator shall include, at a minimum, the following list of critical real-time tools used in the operation and monitoring of the bulk electric system: alarm tools, telemetry data systems (includes applications for SCADA and ICCP Data Link telemetry data), state estimator, network topology processor, and contingency analysis.*

PR1.1.2. Each reliability coordinator and transmission operator shall include, at a minimum, the following list of critical equipment used in the operation and monitoring of the bulk electric system: servers or computers that contain the critical real-time tools specified above and the data links that provide the input to the critical real-time tools specified above.

PR1.2. *Monitoring of Critical Equipment — Each reliability coordinator and transmission operator shall maintain a Critical Equipment Monitoring Document identifying its tools and procedures for monitoring critical equipment (which includes critical real-time applications). This document shall describe how to verify that the tools and procedures are functioning and being used as intended. This document shall describe the tools and procedures for operator notification when critical equipment is unavailable.*

PR1.2.1. Each reliability coordinator and transmission operator shall implement automated tools or organizational processes to monitor critical equipment (which includes critical real-time applications) and related system events to ensure reliable operation of the bulk electric system. These tools or organizational processes shall be described in the Critical Equipment Monitoring Document.

PR1.3. Each reliability coordinator and transmission operator shall maintain event logs pertaining to critical equipment (which includes critical real-time applications) status for a period of one year. At a minimum, the event logs shall contain the following information regarding any event that affects the functionality and/or availability of critical equipment. The event log shall address the following questions: What happened? When did it happen? Who was notified? What was the resolution?

PR1.4. Maintenance of Critical Equipment — Each reliability coordinator and transmission operator shall maintain a Critical Equipment Maintenance and Testing Document identifying its tools and procedures for maintenance, modification, and testing of critical equipment. This document shall describe how to verify that the tools and procedures are functioning and being used as intended.

RTBPTF recommends the following measures for the requirements stated above. The measures related to change management tools and practices are written in italic font.

PM 1. *Measures for Critical Equipment Monitoring*

PM 1.1 *The Critical Equipment Identification Document must be available as specified in Requirement PR1.1. Additionally, each* *reliability coordinator and transmission operator shall demonstrate that the Critical Equipment Identification Document is kept current at all times.*

PM1.1.1. *As specified in Requirement PR1.1.1, the Critical Equipment Identification Document must contain, as part of its list of critical real-time applications, the following applications: alarm tools, telemetry data systems (includes applications for SCADA and ICCP Data Link telemetry data), state estimator, network topology processor, and contingency analysis.*

PM1.1.2. As specified in Requirement PR1.1.2, the Critical Equipment Identification Document must contain, as part of its list of critical equipment, the following equipment: servers or computers that contain the critical real-time tools, and the data links that provide the input to the critical real-time tools specified.

PM 1.2 *The Critical Equipment Monitoring Document must be available as specified in PR1.2. Additionally, each reliability coordinator and transmission operator must demonstrate that the Critical Equipment Monitoring Document is kept current at all times and that the documented tools/procedures are used as intended*.

PM1.2.1. Each reliability coordinator and transmission operator must demonstrate, upon request, its capability to monitor critical equipment via automated tools (e.g., critical equipment status displays or visualization tools) or organizational processes (e.g., trouble notification processes) as stated in Requirement PR1.2.1.

PM 1.3 Each reliability coordinator and transmission operator must demonstrate that the event logs as stated in Requirement PR1.3 contain the required information.

PM 1.4 The Critical Equipment Maintenance and Testing Document must be available as specified in PR1.4.

Rationale

The “Purpose” section of Standard IRO-005 states, “The Reliability Coordinator must be continuously aware of conditions within its Reliability Coordinator Area and include this information in its reliability assessments. The Reliability Coordinator must monitor Bulk Electric System parameters that may have significant impacts upon the Reliability Coordinator Area and neighboring Reliability Coordinator Areas.” RTBPTF believes that information on critical applications’ status is essential to the RC’s continuous awareness of conditions that may impair its ability to operate the bulk electric system reliably. Lack of awareness that critical real-time tools (e.g., FE’s alarm processor application) were unavailable significantly contributed to lack of operator situational awareness in the August 14, 2003 blackout, as noted in the *Outage Task Force Final Blackout Report.*

If a new requirement is not established for monitoring of critical real-time tools, operators may be unaware when these tools (such alarm tools or contingency analysis applications) are unavailable, which could impair their ability to monitor interconnected bulk electric system reliably.

RTBPTF includes TOPs in the recommendations stated above because these entities are subject to the Reliability Toolbox requirement and are required to have the critical equipment that provide the infrastructure for these tools.[13]

Recommendation – G16

Develop a process for monitoring critical real-time tools including change notification, status update, and severity of a situation.

Recommendations for Operating Guidelines

The survey results show that critical applications monitors are widely used by all types of entities in the industry. Although the survey did not quantify the tool's effectiveness, it is clear that awareness of the availability and status of critical real-time tools increases operators' situational awareness, which is essential for reliability monitoring as required by existing NERC standards. Because of the prevalence of critical applications monitor use, the following recommended operating guidelines appear feasible.

RTBPTF recommends development of the following operating guidelines for the critical applications monitor application. These guidelines support the recommended additions to Standard IRO-005-1 described above.

- Each reliability coordinator should have a demonstrated process for monitoring critical real-time tools. This monitoring process should have the objective/purpose of enhancing operator awareness of the availability of critical real-time tools. The monitoring process should, at a minimum, include the following:
    - Notification of management, operators, and support personnel when critical real-time tool are unavailable
    - Analysis and resolution process for critical real-time tool failures

[13] See the Reliability Toolbox Rationale and Recommendation section as well as the recommendations for each tool in the Reliability Toolbox.

- Critical real-time tool status should, at a minimum, be one of the following: (a) available — running, (b) available — stalled, or (c) unavailable. For example, if the critical real-time tool is functioning correctly (i.e., the output data are updating), the application would be deemed AVAILABLE — RUNNING. If for some reason, the application process/task is still alive but the output data from the application are not updating (because of internal application problems/issues), the application would be deemed AVAILABLE — STALLED. If the application/process is dead or non-existent (e.g., the application failed because of a core dump), the application would be deemed UNAVAILABLE.
    - If possible, the critical applications monitor should specify the severity of the situation, i.e., indicate the action to take to return the tool to AVAILABLE — RUNNING status. "High severity" would mean that a total system reboot is necessary to correct the UNAVAILABLE state.

Recommendation – A17

Investigate whether critical application monitor tools should be independent of the critical real-time tool being monitored.

Areas Requiring Additional Analysis

Ideally, in order to ascertain critical real-time tool status, the critical applications monitor tool should be independent of the critical real-time tool being monitored. For example, if the critical applications monitor tool monitors the alarm tools application, the critical applications monitor tool and the alarm tools application should not reside on the same server. Further investigation is needed to determine the prevalence of the use of this scheme throughout the industry.

Examples of Excellence

RTBPTF cites Tennessee Valley Authority's use of a critical applications monitoring tool that monitors all critical and non-critical processes on their SCADA system as an example of excellence (See EOE-20 in Appendix E).

RTBPTF cites International Transmission Company's use of a critical applications monitoring tool that that monitors the status of their state estimator and ICCP data applications as an example of excellence (See EOE-21 in Appendix E).

RTBPTF cites American Transmission Company's use of overview displays that not only show system performance but also EMS health checks as an example of excellence (See EOE-22 in Appendix E). These overview displays allow the system operator to determine whether the EMS is operational and functioning properly.

RTBPTF cites Central and Southwest's use EMS Facilities Monitoring application with its critical applications monitor as an example of excellence (See EOE-23 in Appendix E).

Section 5.5
Trouble-Reporting Tool

Definition

A trouble-reporting tool allows control center tools/applications users (operators and support personnel) to document problems (e.g., application, system, and display difficulties and malfunctions) and resolutions.

Background

RCs, TOPs, and BAs depend on real-time tools to operate the bulk electric system in a coordinated manner and ensure reliable operations under normal and abnormal conditions, as defined in the NERC standards. A trouble-reporting tool allows users to document problems related to critical real-time tools and may also be used to improve existing support processes.

Support processes help ensure the viability of systems and applications that underpin reliability functions in a control center. These processes allow operators to manage control center infrastructure, which evolves as a result of regular technology changes. Computer system outages and lack of infrastructure stability often result from lack of effective support processes, increasing the risk that critical equipment and real-time tools, used by operators to monitor, assess, or perform the actions necessary to maintain the reliability of the bulk electric system, will not be available. As part of support processes, trouble-reporting tools improve computer operations and help control and keep track of trouble report status (e.g., current computer system issues and their estimated time of repair) that may affect operators' situational awareness.

Summary of Findings

Most respondents (67 percent) to the trouble-reporting tool section of the Real-Time Tools Survey have an operational trouble reporting tool. RCs are most likely to use trouble-reporting tools; 94 percent of RCs responding to the survey have these tools. Table 5.5-1 summarizes the survey results.

Entity Type	Percentage of Entities That Have Operational Trouble Reporting Tools
All	31/46=70%
RC	16/17=94%
Others	15/29=52%

Table 5.5-1 — Entities with Operational Trouble-Reporting Tools

Most respondents that have an operational trouble reporting tool rate it "essential" (61 percent) or "desirable" (35 percent) for situational awareness. A minority of respondents (3 percent) rate their trouble-reporting tool as having “no value.” One respondent that rates the tool “essential” states that “the Trouble Reporting Tool is used for having an indication of the usage of the EMS Production Support Resources. Additionally, special application incidents, incident reports, and Software Incident Reports are generated and tracked.” “Essential” ratings varied across entity types (see Table 5.5-2) although RCs were most likely (88 percent) to assign this rating.

Entity Type	How do You Rate the Value of Your Trouble Reporting Tool as a Critical Support Tool to Enhance Reliability Operation and Situational Awareness?		
	“Essential”	“Desirable”	“No value”
All	19/31=61%	11/31=35%	1/31=3%
RC	14/16=88%	2/16=13%	0/16=0%
Others	5/15=33%	9/15=60%	1/15=7%

Table 5.5-2 — Value of Trouble Reporting, by Entity Type

The survey results also show that for most entities (93 percent), the trouble-reporting tool is a stand-alone application that is not integrated into EMSs. No tool features emerged as predominant among entity types. The following features were addressed in the survey:

- Display Attachments — This function allows users to attach displays or bitmap images to a trouble report. This feature allows users to efficiently describe a problem by attaching a display or bitmap image of it. (Forty-seven percent indicate that they have this feature, and 27 percent indicate that this feature is “essential” for situational awareness).
- Summary Reports — This function allows users to generate summaries (e.g., trouble reports by functional area) for analysis of trends. (Fifty-nine percent indicate that they have this feature, and 36 percent indicate that it is “essential” for situational awareness).
- Direct User Feedback — This function allows the application to indicate who originates a trouble report and the current status of the report. (Sixty-two percent indicate that they have this feature, and 28 percent indicate that this feature is “essential” for situational awareness).

Recommendations for New Reliability Standards

RTBPTF does not recommend any new reliability standards requiring use of a trouble-reporting tool. RTBPTF believes that the recommendations in Section 5.2, Change Management Tools and Practices, are sufficient to support operator situational awareness related to critical equipment and critical real-time tool maintenance, modification, and testing processes. RTBPTF believes that the trouble-reporting tool is useful and could be integrated with support processes required by the standards recommended in Section 5.2. The trouble-reporting tool could be used formally to document support processes.

Recommendations for Operating Guidelines

The survey results show that trouble-reporting tools are not as prevalent among industry entities as other tools despite the perceived value of trouble-reporting tools for enhancing support processes. The survey results did not quantify the effectiveness of the trouble-reporting tool, but it appears clear that having a tool to track problems and resolutions related to critical equipment and critical real-time tools will enhance situational awareness for both support personnel and operators. However, because change management processes vary in the industry, RTBPTF does not recommend development of new operating guidelines for trouble-reporting tools at this time. Operating guidelines recommended in Section 5.2 are sufficient.

Areas Requiring Additional Analysis

RTBPTF identified no areas requiring additional analysis for trouble-reporting tools.

Examples of Excellence

RTBPTF cites Florida Power and Light's (FPL) Trouble Report System, which facilitates logging, communication, and tracking of user problems with tools and systems maintained by the computer support group at FPL's System Control Center as an example of excellence (See EOE-24 in Appendix E). In addition to allowing entries of new trouble reports, the application performs administrative functions and can produce different query-based summary reports.

Section 6.0
Next Steps

NERC and the industry have much work to do to implement the RTBPTF recommendations described in this report for revised standards and operating guidelines to improve electric system reliability through better real-time operating tools and practices. In addition, NERC and the industry have much to do to conduct the necessary additional analyses of issues for which the task force could not provide specific, technically defensible recommendations or that were outside task force's scope.

To initiate the next steps in the process, RTBPTF proposes to finish work on the specific activities discussed below, which will complete the remainder of the task force's scope of work as assigned by the NERC Operating Committee (OC). Following completion of these activities, RTBPTF will disband.

RTBPTF's recommendations are intended to inform the standards development process. With assistance from NERC staff, RTBPTF will append its recommendations for revised standards to the existing Standards Review Forms that are included in the NERC Standards Development Plan: 2007–2009.[14] The relevant recommendations will be added to the "To Do List" section of the form for each affected standard along with other issues already identified from various sources such as the *FERC Staff assessment* of the NERC standards and comments on the standards from various industry stakeholders. As the standards development plan proceeds, RTBPTF will provide technical support to the standards drafting teams that will author the necessary revisions in accordance with the NERC Reliability Standards Development Procedure.[15]

RTBPTF will also prioritize the areas that the task force identified as requiring more analysis. For areas that the task force believes must be addressed by a new team of experts, RTBPTF will offer to write high-level scopes of work in the form of bullet points that the new teams should consider in drafting their own charters. RTBPTF will deliver the prioritized list of areas needing additional analysis to the NERC ORS and will prepare scope-of-work bullet points as requested by the ORS.

---

[14] FERC_Filing_Volumes_I-II-III_Reliability_Standards_Development_Plan_30Nov06.pdf on www.nerc.com
[15] http://www.nerc.com/standards/newstandardsprocess.html

Recommendation – I6

Provide adequate funding and staffing for maintaining and upgrading real-time tools.

RTBPTF also recommends that others take two important additional steps that are outside the scope that the OC assigned to the task force. First, the task force recommends that the OC direct the ORS to determine how operating guidelines are to be developed and maintained. Consistent with the work already done by the ORS in this area, RTBPTF suggests that ORS consider asking the regional reliability organizations (RROs) to develop operating guidelines as “supplements” to NERC standards. Second, the task force urges NERC to develop a plan to address each of the “six major issues” identified by RTBPTF and described in the Introduction to this report.

RTBPTF does not take a position on the disposition of the Examples of Excellence listed in Appendix E of this report. They are presented for consideration by NERC and the industry, with the disclaimers noted in Appendix E.

Glossary of Terms Used in this Report

The following are definitions of terms used throughout this report. The report also contains terms as defined in the "Reliability Standards for the Bulk Electric Systems of North America" document.[1]

Term	Definition
Alarm tools	Applications that emit real-time visible and audible signals to alert operators to events and conditions affecting the state of the bulk electric system. Alarm tools can be external, embedded within the SCADA/EMS system, or a combination of both.
Automatic safety bet	Visualization tool that provides the tools/displays for operators to monitor, initiate, or disable triggering of schemes that shed firm load for under voltage or under frequency conditions. Automatic safety net could work with a remedial action scheme monitor.
Outage Task Force Final Blackout Report	U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April.
Bulk Electric System Elements List	A term developed by RTBPTF to refer to a list of specific bulk electric system elements (generators, transmission lines, buses, transformers, breakers, etc.) within an RC area. The Bulk Electric System Elements List shall contain the necessary bulk electric system elements (within the RC area) so that potential or actual SOL/IROL violations could be identified.
Change management tools	Tools and practices used by support personnel to maintain, modify, and/or test critical equipment that operators use to monitor and perform necessary actions to maintain reliability of the bulk electric system.
Commercial/industrial demand-side management	See "Commercial/industrial load management"
Commercial/industrial load management	Tools that enable operators to curtail commercial/industrial electric demand. This type of tool is similar to residential load or demand-side management but is applied to commercial/industrial customers. A typical application of this type of tool is the disconnection of the electric supply feed from the supplying entity through direct computer control by operators to reduce electric demand.
Congestion management application	Application used for relieving network congestion within an entity's service territory using operational means that lie within the entity's control authority, e.g., generation redispatch, curtailment of transactions within the entity's service area, capacitor bank switching, opening low voltage lines, etc. Typically, it may be a security-constrained dispatch program, an optimal power-flow program, or a heuristic program that searches for the best solution from a set of options. For an ISO or an RTO, this may be part of the LMP application.

[1] For these terms, please refer to the Glossary in the latest official copy of the NERC Reliability Standards, which can be found at http://www.nerc.com/~filez/standards/Reliability_Standards_Regulatory_Approved.html.

Term	Definition
Contingency analysis	Computer application used to analyze the impact of specific, simulated outages (lines, generators, or other equipment) or higher load, flow, or generation levels on the security of the system. Contingency analysis identifies problems such as line overloads or voltage violations that will occur if a new event (contingency) happens on the system. The state estimator solution is a representation of current system conditions and usually serves as the base case in the analysis. The information a contingency analysis generates enables RCs and TOPs to implement mitigation plans in advance of a contingent event such as a line trip. Contingency analysis is used as a real-time application as well as for studying potential scenarios.
Critical applications monitoring	Tracks the status of critical real-time tools. This application allows operators and/or support group personnel to track availability of critical real-time tools. Critical real-time tools must be available for operators to monitor, assess, and perform the necessary actions to maintain the reliability of interconnected bulk electric systems. A critical applications monitor tool may be part of a facilities monitor tool.
Critical equipment	Installed equipment that makes up the infrastructure and systems (including communication networks, data links, hardware, application software, and databases) that are directly used as the computer infrastructure for critical real-time tools. Critical equipment is essential for all reliability entities to ensure the reliable operation of the bulk electric system. Critical equipment is a subset of critical cyber assets.
Critical facility loading assessment	Application that evaluates a set of contingencies and calculates the post-contingency loading of a set of monitored facilities using telemetered SCADA flows and LODFs. CFLA may be used as a backup application if the state estimator and/or contingency analysis applications fail.
Critical real-time tool	Installed software that is essential to support, operate, or otherwise interact with bulk electric system operations. Critical real-time tools do not include process control applications, distributed control system applications installed in generating stations, switching stations, or substations.
Display maintenance tool	Tool used by support personnel to develop and maintain visual interfaces that operators use to maintain situational awareness, i.e., to monitor and assess bulk electric system reliability and/or take action to maintain system reliability.
Dynamic mapboard	Physical collection of painted lines, status lights, and analog readouts presenting, in a stationary prominent location, continuous real-time status of important selected components of the power system to operators. It is “dynamic” because the statuses of important selected components of the power system are updated in real time. A dynamic mapboard usually complements common SCADA/EMS displays.

Term	Definition
Dynamic overview display	One-line and other graphical displays depicting the state, loading, and/or voltage levels over the wider area (or a sub-area within the entity's internal footprint) of the power system. Dynamic overview displays are essentially large SCADA one-line displays. Examples of this type of visualization tool are area overview one-line displays, which are one-line displays that show a group of electrically connected substations for a specified area.
Dynamic stability assessment	Application (or a suite of applications) executing in near-real time that aid in determination of system operating limits based on transient dynamic stability assessment using a current state estimator model of the real-time system. A dynamic stability assessment may also provide an indication of the dynamic stability margin for the most critical fault/contingency condition.
Emergency tools	Applications or procedures that operators use when the power system enters or is about to enter an emergency. The NERC Glossary defines "emergency" as "[a]ny abnormal system condition that requires automatic or immediate manual action to prevent or limit the failure of transmission facilities or generation supply that could adversely affect the reliability of the Bulk Electric System."
Facilities monitor	Tracks the status of computer systems equipment, servers, backup systems, communications systems, networks and other critical facilities. This tool allows operators and/or support personnel to be aware of critical equipment issues that may affect the availability of critical real-time tools used to operate and monitor the bulk electric system.
Flowgate monitor	Visualization tool that provides the tools/displays for operators to monitor actual and contingency flows on designated flowgates. The NERC Glossary defines "flowgate" as "[a] designated point on the transmission system through which the Interchange Distribution Calculator calculates the power flow from Interchange Transactions." This type of visualization tool provides flowgate information to operators; it could run either within or independent of SCADA/EMS systems.
Inter-control center communications protocol	Inter-Control Center Communications Protocol (ICCP) is a standard data exchange protocol that is widely used in the electric utility industry to communicate information between operating entities. The NERC ISN utilizes ICCP to support data exchange among RCs, and several intra-regional and intra-company networks also use this protocol to support the provision of data to RCs from operating entities within the RC area.
Inter-regional real-time coordination for market redispatch	Application used to adjust the market dispatch within the entity's service territory in coordination with adjacent RCs to manage the inter-regional congestion problem in real-time. This tool may be handled by the entity's congestion management application, or it may be handled through a different process.

Term	Definition
Inter-regional voltage profile coordination	Application that coordinates the voltage profiles between two or more regions. This application may contain features such as wide-area voltage contour visualization, voltage schedule coordination between regions, etc.
Line outage distribution factor	Estimation of impact from an outage over a facility can be done using LODF. In general, an outage impacts the system by transferring the amount of power flowing on the outaged elements during pre-contingency conditions to other facilities in the system. These changes could increase or decrease power flow on the facilities depending on network topology, load, and generation dispatch. LODF is formulated as a percentage of pre-contingency flow on the outaged line that appears on the monitoring facility during contingency conditions.[2]
Load reduction by voltage reduction	Enables the operator to curtail electricity demand by reducing the distribution-level voltages. This scheme usually involves direct computer control (via SCADA systems) to automatic voltage regulating relays on LTC power transformers and step voltage regulators. By means of the control of the dry contact closure to the regulating relay, its regulating center band voltage is reduced to a lower level by boosting the sensed voltage of the voltage regulating relay. This causes a reduction of the distribution voltage schedule, which reduces electricity demand for a short period.
Locational marginal pricing	A market-pricing approach used to manage the efficient use of the transmission system when congestion occurs on the interconnected bulk electric system.
Network topology processor	SCADA-based application that determines facility status and station configuration based on breaker and switch status data. The processor converts a nodal network model into a bus-branch model, for use by other applications such as the state estimator. It may perform the same function for study network applications such as power flow.
Offline power flow	See “Power Flow”
Online power flow	See “Power Flow”
Operator	System operator
Power flow	Application used to calculate the state of the power system (flows, voltages, and angles) by using available input data for load, generation, net interchange, and facility status. Power flow is divided into two categories: “online power flow” and “offline power flow.” An “online power flow” application is typically integrated within an EMS (or has a direct data feed from an EMS) and utilizes node-breaker topology whereas “offline power flow” is based on bus-branch models and static data. Power flow is widely used in real-time systems to assess system conditions or perform look-ahead analysis. Power flow is also used to study “n-1” contingencies and to identify potential future voltage collapse or reliability problems.

[2] Source: http://www.caiso.com/docs/2005/05/03/200505031714217356.pdf.

Term	Definition
Reactive reserve monitor	Visualization tool that allows operators to monitor reactive reserves (from static and dynamic sources) in local geographic areas or major load centers. This visualization tool can alarm the operator when a generating unit has reached its reactive capability or an area has approached the minimum reactive reserve requirement. This type of visualization tool could also be the real-time user interface representation of the documented set of procedures, practices, or guidelines for maintaining awareness of the current and near-term reactive reserve capability.
Real-Time Tools Best Practices Task Force	The task force responsible for this report
Real-time contingency analysis	See "contingency analysis"
Remedial action scheme monitor	Visualization tool that provides the tools/displays for operators to monitor the status of critical power system parameters and measure the proximity of these parameters to the triggering conditions for special protection schemes or total system failure. This tool alarms and advises operators of actions required to mitigate the pending power system condition.
Residential demand-side management	See "residential load management"
Residential load management	Enables the operator to curtail residential electric demand for specific appliances. Residential load or demand-side management (DSM) consists of planning, implementing, and monitoring activities designed to encourage residential consumers to modify their level and pattern of electricity usage. These activities are also designed to shape electricity demand through direct computer control of specific appliances. For example, when necessary, operators could turn off air conditioners of residential customers that sign up for a residential DSM program.
Rotating load shed	Enables the operator to curtail load by initiating or scheduling load shedding. The *Outage Task Force Final Blackout Report* defines "load shedding" as "… the process of deliberately removing (either manually or automatically) pre-selected customer demand from a power system in response to an abnormal condition, to maintain the integrity of the system and minimize overall customer outages." For this type of tool, rotating load shed refers only to manual load shedding scheduled or initiated by operators via computer control.
SCADA one-line display	Dynamic, one-line diagram displays of substations and major power system components that present the real-time status and selected flow, voltage, and other data of the power system. This is the most common type of visualization tool used today to monitor bulk electric system elements or parameters.
Security-constrained dispatch	See "congestion management application"
Selectable data trending	Visualization tool that provides the ability to plot graphically selected power system values, using up-to-date data on the plot at a reasonable refresh rate on real-time displays used by operators and others. Displays are used by system operators and others.

Term	Definition
Short-term load forecasting	Application that predicts short-term (next 0-60 minutes) loads based on parameters such as short-term weather effects, current load, etc. The result from this tool could be used for predictive redispatch, look-ahead contingency analysis, awareness of scheduled non-conforming load changes, etc.
Short-term weather forecasting	Application that predicts short-term (next 0-60 minutes) extreme weather that may impact operations, e.g., a lightning prediction tool, Doppler radar, etc.
Short-term wind energy forecasting	Near real-time application that is used to predict and manage generation in response to the variability of supply from wind-energy sources.
Short-term hydro scheduling	Real-time application used to manage deviations from the long-term optimized schedule (for hydro units) for reasons of reliability, e.g., a response to a DCS event, acquiring support for localized voltage control, etc.
State estimator	Application that performs statistical analysis using a set of imperfect, redundant, telemetered power system data to determine the system's current condition. The system condition or state is a function of several variables: bus voltages, relative phase angles, and tap changing transformer positions. A state estimator can typically identify bad analog telemetry, estimate non-telemetered flows and voltages, and determine actual voltage and thermal violations in observable areas. The state estimator application has two main uses. It provides (1) a base case for reliability-analysis applications, and (2) input to other system monitoring tools. The state estimator solution is typically used as the base case for other reliability-related applications, such as contingency analysis. In some cases, the state estimator is used primarily as the basis for information communicated to operators regarding power system status, e.g., the state estimator drives the alarm application that alerts operators to power system events.
State estimator one-line display	Dynamic, one-line diagram displays of substations and major system components that present the state estimator solution for status and selected flow, voltage, and other data from the power system.
Study area one-line display	Study area one-line displays are one-line diagram displays of substations and major system components that present the active study context of status and selected flow, voltage, and other data from the power system model in use. Examples of this type of visualization tool are power flow one-line displays, contingency analysis one-line displays (for a specified contingency), etc.
Study real-time maintenance	Application that simulates real-time network applications (e.g., NTP, state estimator, contingency analysis, etc.) and debugs problems without affecting the operation of the real-time applications. Can be an on-line application integrated with the production EMS system, an application integrated with a non-production EMS system (i.e., DTS, etc.), or an off-line application.

Term	Definition
Telemetry data	Status and analog values originating from conventional SCADA/EMS or equivalent systems (telemetry data systems) and are updated continuously in real-time or near-real-time operation. These data may come directly from SCADA system(s) or from direct connection (ICCP, ISN, etc.) to SCADA systems operated by others.
Telemetry data systems	Tools or applications that process and provide telemetry data. SCADA is an example of a telemetry data system.
Topology and analog error detection	Application that identifies and/or automatically overrides incorrect SCADA breaker and switch statuses to enhance a NTP and to improve the accuracy and robustness of the state estimator. May also identify and/or automatically ignore SCADA analog measurements that are unreasonable or inconsistent with network connectivity.
Transaction impact monitor	Type of visualization tool that provides the tools/displays for operators to monitor scheduled transactions and interchange flows between balancing authorities.
Trouble-reporting tool	Allows control center tools/applications users (operators and support personnel) to document problems (e.g., application, system, and display difficulties and malfunctions) and resolutions.
Visualization tools/techniques	A group of user interface applications, tools, or displays that provide concise visual monitoring and enhanced multiple views of relevant power system data in real time to operators and others. Visualization tools help operators monitor and better understand system events and/or conditions across neighboring power systems that may be affecting reliable operations in their part of the power system.
Voltage stability analysis	Application executing in near-real time that aids in determination of system operating limits based on voltage stability assessment using a current state estimator model of the real-time system. VSA may derive minimum voltages at key buses below which voltage collapse may occur under further stress to the system, evaluate whether sufficient stability margins exist for an analyzed base case, provide margins relative to particular stress modes such as transfers or system loading, or provide information on minimum dynamic reactive reserves required in local areas.
Wide-area view boundary	The NERC glossary defines “wide area” as “[t]he entire Reliability Coordinator Area as well as the critical flow and status information from adjacent Reliability Coordinator Areas as determined by detailed system studies to allow the calculation of Interconnected Reliability Operating Limits.” RTBPTF defines “wide-area view boundary” as the network model boundary for the “wide area.” For reliability coordinators, the “wide-area view boundary” defines the minimum required network model in order to support the monitoring requirements for the “wide area.” This network model should contain all the bulk electric system elements (generators, transmission lines, buses, transformers, breakers, etc.) bounded by the wide area view boundary.

Term	Definition
Wide-area visualization tools	Displays/tools driven by SCADA, EMS, PMU, disturbance recorder, and other technical data collected in real time that present concise information for the "wide area." In general, these displays/tools show multiple views of the status of critical facilities within the entity's internal footprint, but they are also used to show views of critical facilities or data from the entity's external footprint that have the potential for adverse impact to the internal system (the "wide area" as defined in the NERC Glossary). By this definition, dynamic overview displays may also be considered wide-area visualization tools. Besides the traditional SCADA/EMS displays that show critical reliability parameters, wide-area visualization tools use other forms of technology/methodology to present vast amounts of information in a form such that the operator can assess the state of the system in an intuitive and quick manner.

Appendix A
Real-Time Tools Survey Development and Software

Introduction

RTBPTF's scope includes the assignment to "develop a focused survey (preferably web-based) for distribution to entities responsible for reliable operations to determine which tools those entities use to perform state estimation, perform real-time contingency analysis, and maintain situational awareness of their systems." To fulfill this assignment, the task force developed the Real-Time Tools Survey and delivered it as an interactive, on-line, web-based questionnaire. Lawrence Berkeley National Laboratory provided programming, database, and systems integration services for the survey. This Appendix summarizes the survey's development and briefly describes the software system that was created to support it, including its testing, quality assurance, and role in the survey analysis.

Summary of Survey Development

The survey in its final form was more than 300 pages long, with nearly 2,000 questions organized into five major sections: Real-Time Reliability Tools, Situational Awareness Practices, Real-Time Data Acquisition and Exchange, Modeling Practices, and Support and Maintenance Practices related to the real-time tools.

Real-Time Tools

The initial basis for the selection of the real-time tools investigated in the survey was a report on minimum requirements and best practices for reliability software, presented at a July, 2004 FERC technical conference on Information Technology for Reliability and Markets, (Docket No. PL04-12-000).[1] Starting from the applications addressed in that presentation, RTBPTF narrowed the list to real-time operator tools. (The task force did not consider long-term, medium-term, day-ahead, training, or market or economic operations tools.) Based on their collective expertise and experience, the task force members then developed a complete list of reliability tools that directly support situational awareness and formulated definitions for each tool. Special emphasis was placed on tools to aid operator situational awareness because the *Outage Task Force Final Blackout Report* repeatedly points to lack of operator situational awareness as a key cause of the August 14, 2003 blackout. The real-time tools portion of the survey was designed to elicit, from different types of entities responsible for reliable

---

[1] Macedo, Frank. Consultant to FERC. 2004. *Reliability Software Minimum Requirements & Best Practices*. FERC Technical Conference, July 14. http://www.ferc.gov/EventCalendar/Files/20040716092511-20040714085315-FrankMacedo.pps

operation of the bulk electric system, descriptions of their use of each tool. The task force's goal was to characterize, based on the survey results, each tool's industry-wide status.

Situational Awareness Practices

The task force reviewed the then-current NERC reliability standards to identify elements of situational awareness that were addressed to some extent in the standards. These elements formed the basis for survey questions on operating practices, processes, and procedures used to maintain situational awareness.

Data, Modeling, and Support and Maintenance Tools

The three remaining sections of the survey address the acquisition and exchange of real-time data needed to support real-time reliability tools and practices, the characteristics of the real-time models needed to support those tools (as well as the practices used to build and maintain the models), and other tools and practices to support and maintain real-time reliability tools. These topics were included in the survey because real-time reliability tools require accurate input data, well-designed models, and effective maintenance to produce meaningful results that operators can depend on for situational awareness.

Survey Structure

Task force members extensively debated the optimal structure for the individual questions in the survey. Some members felt that asking general questions that required a detailed, free-format written response would elicit the most comprehensive and insightful information and thus the best basis for identifying candidates for follow-up questioning. The downside to this structure would have been the enormous challenge of analyzing the responses, especially for a questionnaire of this length.

Some task force members favored an alternative structure with sets of specific questions on a particular subject, each having yes/no or multiple-choice answers, designed to elicit, in the aggregate, a complete picture of a topic but requiring minimal effort from respondents. The upside of this approach is that the responses could be easily queried, sorted, and analyzed statistically. The downside is that respondents could not elaborate on their answers.

The final decision was to use a yes/no, multiple-choice structure but to give respondents the ability to add free-format written comments on key topics addressed in the questions.

Each section of the survey described above was broken into individual subsections that addressed specific tools or practices. Within each subsection, the questions were designed and arranged to: identify the types of entities using the tool or practice; inventory the functions of the tool or practice; and rate the value of the tool, function, or practice for situational awareness. In addition, survey respondents were asked to identify what they perceive as *best practices* in their control centers for the particular tool or practice.

The task force finished designing the survey in April 2005 and sent it to Lawrence Berkeley National Laboratory for programming. Beta testing began in June 2005, and the survey was rolled out to reliability coordinators (RCs), transmission operators (TOPs), and balancing authorities (BAs) in August 2005. The task force closed the survey in November 2005 and began analyzing the results in preparation for this final report. The task force presented an overview of its preliminary findings and recommendations to the NERC Operating Reliability Subcommittee (ORS) in November 2006.

Survey Hardware and Software

The RTBPTF on-line survey has two internal components: a web server, and a database, as illustrated in Figure A-1. A secure web server, maintained by NERC staff in Princeton NJ, hosted the survey software. The database stored the questionnaire structure and all of the users' responses. The software generated the web pages through which respondents navigated to read the questions and insert answers by reading directly from the design data (e.g., section, question number, question text, question type) stored in the questionnaire portion of the database. Figure A-2 shows examples of the user interface web pages. All communication between users and the questionnaire took place over an encrypted channel to ensure the security of users' responses. The software used to produce the web site and control the database is written in PHP (www.php.net), which interacts with a MySQL (www.mysql.com) database.

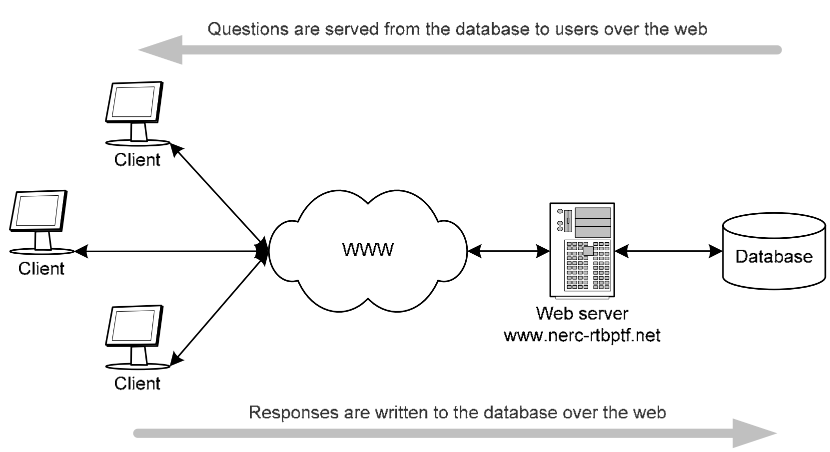

Figure A-1 — Software Communication

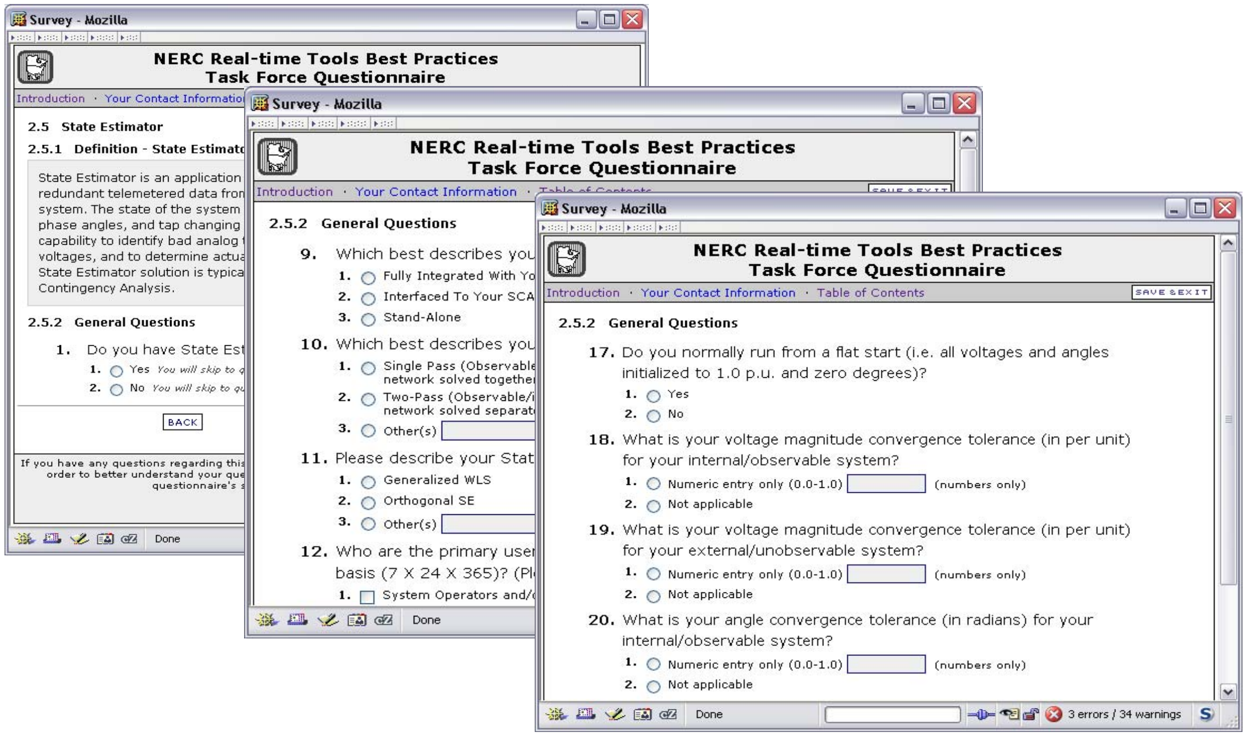

Figure A-2 — User Interface Web Page Examples

Testing

To ensure ease of use and confirm the accuracy of the software application, task force members tested it rigorously prior to release for both completeness and functionality (e.g., navigation among and within survey sections). Improvements in questionnaire content entailed adding or editing database records to add or edit questions. Improvements in questionnaire functionality (e.g., to aid navigation by respondents) entailed direct modifications to the interface software.

Quality Assurance

After the survey period ended, additional software tools were developed that were tailored to task force needs, to interrogate the database and assess consistency among and completeness of user responses. In a few cases, individual users were contacted to clarify conflicting responses.

Interfaces were built on the web server with the following functionalities:

- View survey completion counts by reliability region,
- Download aggregate results of all answers in spreadsheet format,
- View user profiles and download their surveys by reliability region, and
- View aggregate responses for individual questions.

Results/Deliverables

Final output from the questionnaire database was provided in two formats: 1) a report of aggregate responses for each survey question (which can be downloaded as pdfs at: http://www.nerc.com/~filez/rtbptf.html), and 2) the entire questionnaire database in Microsoft Access format.

The report of aggregate responses summarize all responses for each survey question. Responses are presented first aggregated for all respondents, followed by an aggregation of responses received from reliability coordinators.

To mask individual respondents' identities, all comments entered in free-format text fields were globally post-processed to remove references to a specific entity name. These references were replaced with a generic label or term, depending on the context.

The Microsoft Access database containing the raw survey responses is an abridged version of the master MySQL database. Data in the MySQL database specific to the functioning of the web site were not ported to the abridged version. Only data specific to the questions, answers, and respondents were included. The members of the task force received the abridged version to support their individual interrogation and analysis of the questionnaire responses. Figure A-3 shows the database schema.

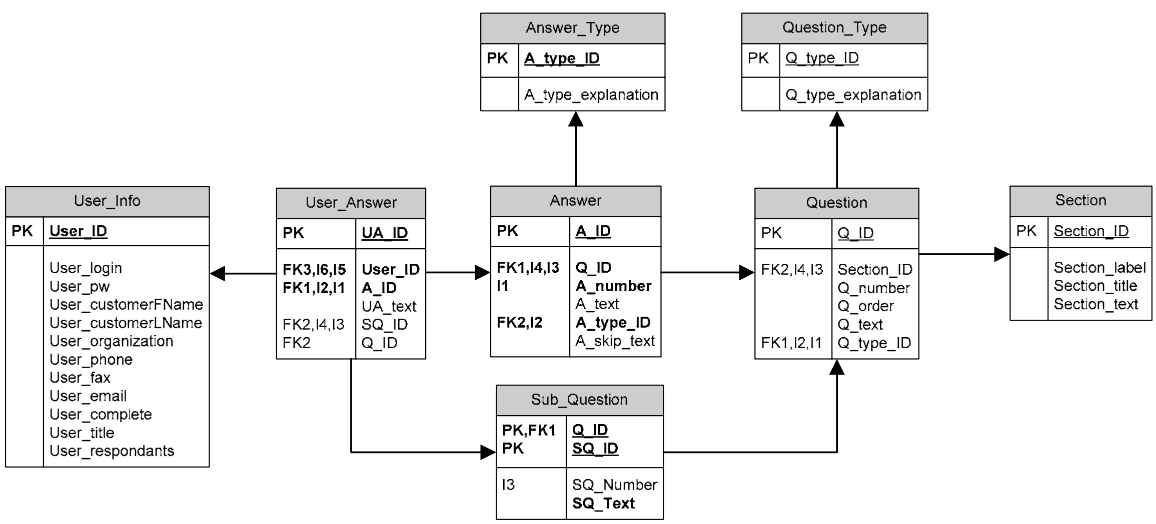

Figure A-3 — RTBPTF Questionnaire Database Schema

Appendix B
Survey Participation

The Real-Time Tools Survey was designed to collect information from NERC registered RCs, TOPs, BAs, and other interested (but unregistered) operating entities who use real-time tools to monitor or analyze the reliability of the bulk electric system. RTBPTF invited representatives from each entity listed in the NERC Transmission System Information Network (TSIN) database to participate in the survey. A total of 59 entities (registered and unregistered) requested access to the survey and completed at least one section. Entities that did not complete at least one section were excluded from the analysis. The survey participants included all 17 North American RCs, 39 TOPs, and 3 BAs (who are not also TOPs or RCs).

Several entities that completed the survey perform more than one NERC function. For example, some entities may serve as both a TOP and a BA; others [e.g., the Electric Reliability Council of Texas] may even serve as RC, TOP, <u>and</u> BA. RTBPTF contacted these "multi-function" entities to clarify their status, and each was reclassified, for purposes of the survey, according to its highest-level function. RCs are considered the highest-level entities, and balancing authorities are considered the lowest-level entities, with TOPs in the middle. Thus, for example, an entity registered as a TOP and an RC would be classified as an RC for the survey analysis; an entity registered as a BA and a TOP would be classified as a TOP. This classification protocol was used to ensure that the information submitted by each participant was not counted more than once in the final analysis of survey results.

Some entities' situations posed classification challenges. One RC contracts some or all of its real-time reliability tools through a registered TOP. The survey response submitted by the TOP for this entity included the RC's response. Therefore, after contacting both entities, the task force reclassified the TOP's response as an RC response. One entity that responded to the survey was not a NERC registered RC, TOP, or BA. After the task force contacted this entity, its response was classified in the category that most closely corresponded to its role.

The entities that participated in the survey are listed below according to the function assigned to each for survey analysis purposes. Figure B-1 shows a map of the geographical footprint of RCs that participated in the survey, and Table B-1 lists the RCs. Figure B-2 shows the footprint of the TOPs and BAs that participated in the survey, and Tables B-2 and B-3, respectively, list the TOPs and BAs.

Reliability Coordinators	
1	Bonneville Power Administration (BPAT) for Pacific Northwest Security Coordinator
2	Southern Company Services, Inc. (SOCO) for Southern Subregion
3	Entergy Services, Inc. (EES)
4	Energy Reliability Council of Texas Independent System Operator (ERCOT)
5	Florida Reliability Coordinating Council (FPL / FRCC)
6	Hydro-Quebec TransEnergie (HQT)
7	The Independent Electricity System Operator (IMO)
8	Independent System Operator New England (ISNE)
9	New Brunswick System Operator (NBSO)
10	New York Independent System Operator (NYIS)
11	Pennsylvania-New Jersey-Maryland Interconnection (PJM)
12	Duke Energy Corporation (DUK) for VACAR-South
13	California Mexico Reliability Coordinator (CMRC)
14	Midwest Independent System Operator (MISO)
15	Rocky Mountain - Desert Southwest Reliability Coordinator (RDRC)
16	Southwest Power Pool (SWPP)
17	Tennessee Valley Authority (TVA)

Table B-1 — Entities who participated in the Real-time Tools Survey and were classified as RCs

Transmission Operators	
1	Alabama Electric Cooperative, Inc. (AEC)
2	Alberta Electric System Operator (AESO)
3	American Electric Power (AEP) - Central & Southwest (CSWS)
4	Associated Electric Cooperative, Inc. (AECI)
5	Cinergy Corp (CG&E)
6	Cinergy Corp (PSI)
7	Cleco Corporation (CLEC)
8	COMISION FEDERAL DE ELECTRICIDAD (CFE)
9	First Energy (FE)
10	Idaho Power Company
11	International Transmission Company (ITC)
12	Lincoln Electric System (LES)
13	Northern Indiana Public Service Co. (NIPS)
14	NorthWestern Energy (NWMT)
15	Oklahoma Gas & Electric (OKGE)
16	Otter Tail Power Company (OTP)
17	Public Service Company of New Mexico (PNM)
18	Grant County Public Utility District (GCPD)
19	Public Utilities District # 1 of Douglas County (DOPD)
20	Santee Cooper (SC)
21	Saskatchewan (SPC)
22	Sierra Pacific Power Company (SPPC)
23	South Carolina Electric & Gas Company (SCEG)
24	Southern Minnesota Municipal Power Agency (SMP)
25	Southwestern Public Service - Xcel (SPS)
26	Tennessee Valley Authority (TVA)
27	Vectren Energy Delivery of Indiana (VEDI)
28	Westar (WR)
29	Western Area Power Administration - Upper Great Plains Region (WAUW)

Appendix C
Survey Analysis Methodology

Introduction

Given the breadth and depth of the Real-Time Tools Survey, RTBPTF recognized that reviewing and analyzing the survey responses would be a monumental task. This appendix explains the methodology that the task force developed to summarize and analyze the survey results and to develop recommendations from them.

Individual task force members reviewed and analyzed specific survey sections and prepared the corresponding portions of this report. To process the massive number of data from the survey, the task force used summary reports and database query tools. To ensure consistency and uniformity of individual reviewers' efforts and to produce this final, comprehensive report, the task force created and followed a structured methodology and a checklist of key steps.

The sections below describe the tools; checklist; and underlying criteria, principles, and guidelines that the task force used in analyzing the survey data.

Analysis Tools

RTBPTF members accessed the database of all survey responses on a secure web site hosted by NERC. Lawrence Berkeley National Laboratory (LBNL), which created the survey software, also created summary reports of responses organized by survey section. These reports were posted on the secure web site, so task force members could download them. In addition, LBNL created an on-line tool that enabled task force members to query the responses to any individual question and see a breakdown by respondent type – RC, TOP, and/or BA.

Task force members could also download the entire survey database and create their own custom queries and reports. One task force member created a summary report of the entire database in a text format and shared it with the other members. Other members created and shared database queries, indices, spreadsheets, and tables.

Survey Review Checklist

The task force created a checklist that outlined the "roadmap" for the complex journey from raw survey responses to the material needed to prepare a final report that would fulfill the task force's deliverables requirement. The checklist contained the following steps:

- Download and review the results file for each task force member's assigned section

- Use Question Query Tool to review responses to particular questions by entity type
- Download survey database into Microsoft Access and design custom queries as needed
- Prepare initial, high-level lists of findings
- Identify related questions from other sections to validate/invalidate initial findings
- Review initial findings in relation to the report on minimum requirements and best practices for reliability software presented at 2004 FERC technical conference on Information Technology for Reliability and Markets[2]
- Refine and summarize initial findings
- Develop recommendations for new standards based on summary of findings
- Develop recommendations for operating guidelines based on summary of findings
- Identify areas requiring more analysis based on summary of findings
- Identify examples of excellence based on survey responses and follow-up interviews

Principles for Summarizing Findings

To ensure that they did not stray from RTBPTF's scope, the task force members focused, when summarizing the survey findings, primarily on issues directly related to reliability and situational awareness. Thus, they undertook to address causes of the August 14, 2003 blackout that were related to real-time tools and situational awareness, as identified in the NERC Steering Group Report to BOT[3] and the *Outage Task Force Final Blackout Report*.[4] In addition, RTBPTF members reviewed existing reliability standards to identify the ones containing requirements related to the tools or practices covered in the survey and to determine which standards needed new or revised requirements. After FERC

issued its *Staff Assessment* of NERC's proposed reliability standards,[5] RTBPTF endeavored to address the issues raised in the assessment that were germane to the task force's scope.

In summarizing survey findings, the task force differentiated between the responses of RCs and those of other survey participants where possible and relevant. One reason for breaking out RC responses was to highlight any major differences between the reliability tool use and operating practices of RCs and those of other entities. Another reason was that all 17 RCs responded to the survey, so, in statistical terms, the total population of RCs was represented. However, only about one-third of registered TOPs and BAs (who are not also RCs) participated, so those responses represent non-random samples of the populations of TOPs and BAs.

RTBPTF looked for clear majorities in the responses to questions about tool usage and practices to identify prevalent practices, which help form the rationale for many of the recommendations in this report. The tables and statistics in the technical sections of this report are designed to illustrate how many respondents answered specific questions in particular ways. In writing their analyses, task force members attempted to summarize the conclusion supported by each set of statistics and tables.

Other guiding principles for summarizing survey results included: 1) quoting survey respondents' comments when quotes are appropriate and help make a point, 2) not self-censoring findings and recommendations because of anticipated controversies, 3) identifying areas in which most respondents seem to be doing well, 4) identifying areas where the industry in general needs improvement, and 5) identifying important issues where the data are insufficient to properly evaluate a tool or practice or are too inconclusive to justify action.

Criteria for RTBPTF Recommendations

RTBPTF's recommendations in this report are based upon several criteria that the task force established to determine which of the following four options were justified by the survey findings for each topic: 1) recommendation for new reliability standards (or revisions to existing standards), 2) recommendation for operating guidelines, 3) identification of areas requiring more analysis, or 4) identification of examples of excellence. These four options were derived from the task force's understanding of its assigned responsibilities as explained in the discussion of "best practices" in the Introduction to this report. The specific criteria for each option are described below.

---

[5] Federal Energy Regulatory Commission (FERC). 2006. *Staff Preliminary Assessment of the North American Electric Reliability Corporation's Proposed Mandatory Reliability Standards*. www.ferc.gov/indus-act/reliability/standards.asp.

Basis for Recommending New or Revised Reliability Standards

1. Recommendations for revisions to existing standards must support or provide clarification to the existing standards.
2. Recommendations for new reliability standards must pertain to tools or practices that materially affect bulk electric system reliability.
3. Recommended requirements must be measurable.
4. All recommendations must support the NERC Reliability and Market Interface Principles.[6]
5. Recommendations must be made by consensus of RTBPTF's active members.
6. Recommendations should support the needs and gaps identified by the NERC and Outage Task Force *Blackout Reports* and the FERC *Staff Assessment* of NERC standards.

Basis for Recommending Operating Guidelines

RTBPTF's criteria for recommending operating guidelines are based to some extent on the criteria for establishing "Best Practices" identified by the NERC Operating Committee's Best Practices Task Force in its report,[7] which was approved by the NERC Operating Committee in December 2005. A key recommendation of the Best Practices Task Force was that "Operating Guidelines" and "Examples of Excellence" should be established in lieu of "Best Practices." RTBPTF's criteria for recommending practices to be documented as operating guidelines are as follows:

1. Practice must be prevalent within the industry (employed by >50 percent of survey respondents).
2. Practice must support an existing or proposed standard.
3. Practice must be proven to be effective.
4. Practice cannot be considered to be essential to maintaining bulk electric system reliability (because operating guidelines are not mandatory).
5. Practice must be feasible to implement.
6. Practice must be applicable over a wide range of organizations that perform the practice for which the operating guideline applies.

---

[6] ftp://ftp.nerc.com/pub/sys/all_updl/tsc/stf/ReliabilityandMarketInterfacePrinciples.pdf
[7] *Best Practices Task Force Report: Discussions, Conclusions, and Recommendations*. 2005. December 1.

Basis for Identifying Areas Requiring More Analysis

1. Were the survey results inconclusive?
2. Was the tool or practice not adequately addressed in the survey?
3. Is the topic a significant “hole” in the overall reliability “fabric?”

Basis for Identifying an Example of Excellence

Because the Real-Time Tools Survey was completed prior to the Best Practices Task Force final report mentioned above, which recommended that "Operating Guidelines" and “Examples of Excellence" be established in lieu of "Best Practices," the survey results included “Best Practices” that were self-nominated by survey respondents. RTBPTF reviewed the nominations and attempted to identify the practices related to tools and/or operating practices that go beyond the minimum requirements of existing standards and are unique to individual organizations but may not be applicable throughout the industry.

The criteria used to differentiate the self-nominated practices and develop the examples listed in this section of the report are as follows:

1. Example must be nominated by either the individual entity or a task force member, and must be approved by both.
2. Example can be assumed to function as stated, i.e., task force will not verify functionality.
3. Recommendations that do not demonstrate an understanding of the tool or a practice discussed in the report will not be considered.
4. Example must be an existing practice, not a desired or planned practice for which empirical results have not been established.
5. Example must be considered not to be commonly used by the majority of the industry; however, the task force will not conduct a side-by-side comparison of each respondent’s practices.
6. Example must be an outstanding practice that the industry could strive to achieve.
7. From survey responses, the task force identified self-nominated “best practices.”
8. Identified best practices were correlated with examples of excellence from NERC readiness audits.

In lieu of conducting face-to-face interviews with the respondents who self-nominated an example of excellence, the task force conducted follow-up email surveys with those respondents. The follow-up surveys consisted of the following questions:

1. Have User fully describe the tool/practice:
    a. What does it do?

    b. Who uses it?
    c. What are the inputs/outputs?
    d. What is the user interface?
    e. What is/was the alternative practice?
2. How does it enhance reliability and/or situational awareness?
3. Which reliability standard(s) does it help meet or exceed?
4. What did it take to implement?
5. What does it take to maintain?

Appendix D
Real-Time Tools Survey

The RTBPTF Real-Time Tools Survey questionnaire and the survey results are available at http://www.nerc.com/~filez/rtbptf.html.

Appendix E
Examples of Excellence

Introduction

Real-Time Tools Survey participants were given an opportunity to document a potential example of excellence. RTBPTF reviewed each proposed example of excellence and in some instances requested additional information before deciding to include it in this report. Appendix E presents all the examples of excellence that RTBPTF recommends to the industry for further consideration.

A detailed description of each example of excellence follows, with cross reference to the section of the report in which the example is identified.

Examples of Excellence

EOE-1

Reference — Section 1.1, Telemetry Data

Submitted by — Northeast Power Coordinating Council (NPCC)

Description

RTBPTF has recommended modifications to existing NERC reliability standards with regard to monitoring of bulk electric system elements/parameters. Section 1.1, Telemetry Data, addresses the need to clarify the definition of the term “bulk electric system.” RTBPTF recommends that RCs produce a document called the Bulk Electric System Elements List to specify the elements/parameters monitored within a reliability area. RTBPTF cites the Northeast Power Coordinating Council (NPCC) as an example of excellence in establishing and facilitating a process/methodology for classifying bulk power system elements within the NPCC RRO. NPCC’s “Criteria for Classification of Bulk Power System Elements (A-10)” document (http://www.npcc.org/document/abc.cfm) is used to identify elements to which NPCC bulk power system criteria apply. NPCC’s A-10 Criteria document recognizes that each RC area has an existing list of bulk power system elements.

RTBPTF believes that NPCC’s methodology for classifying bulk electric system elements qualifies as an example of excellence and exemplifies the RTBPTF recommendation of producing a Bulk Electric System Elements List.

Examples of Excellence

EOE-2

Reference — Section 1.2, ICCP-Specific Data
Submitted by — ISO New England

Description

ISO New England and its transmission owners have implemented an automated trouble-tracking system that includes processes and procedures for reporting, notification, tracking, resolution, and escalation of ICCP data problems.

General Information

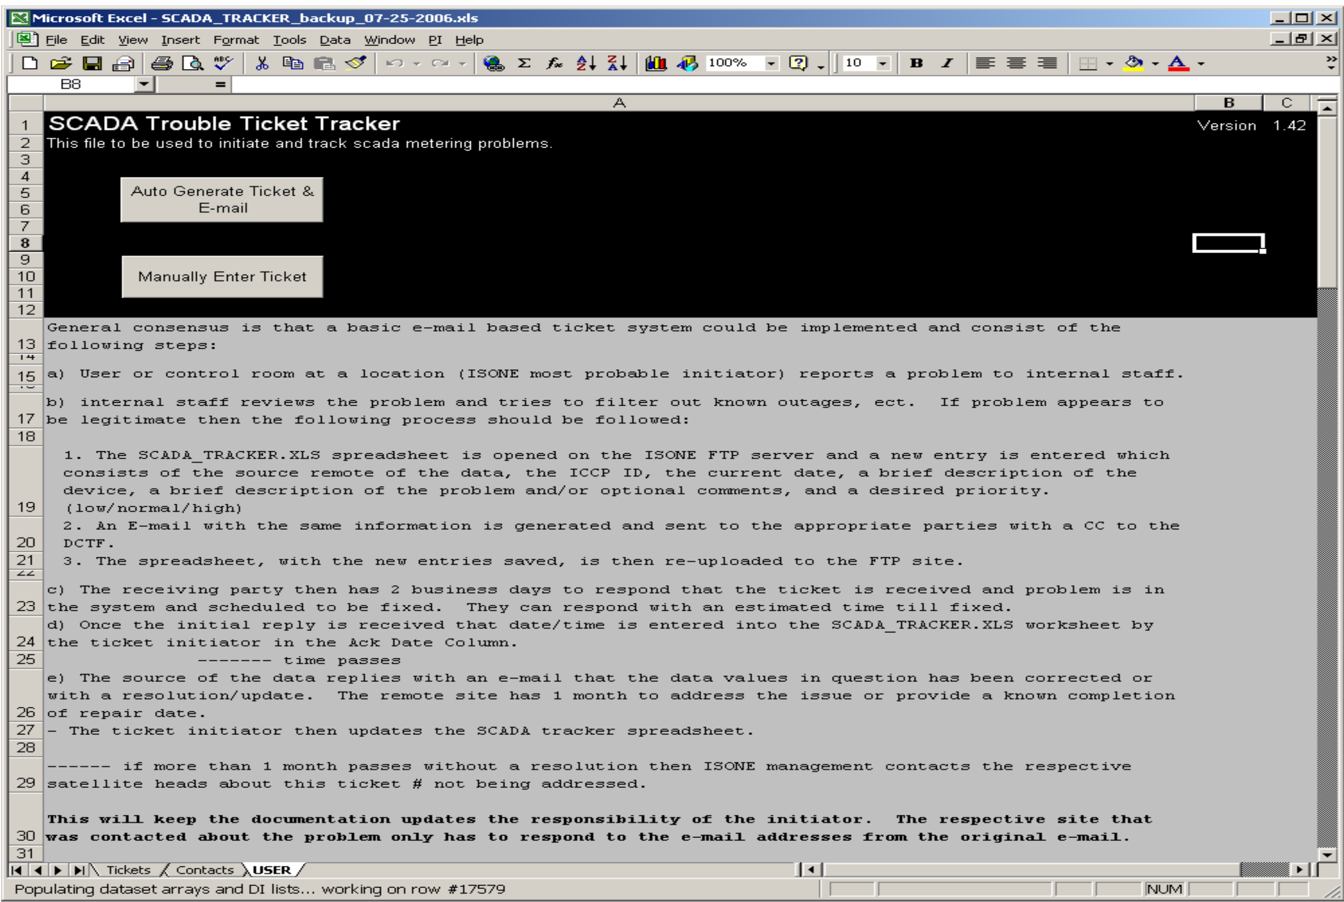
- Tool/Practice Name
  - SCADA TRACKER, a set of procedures, and an Excel spreadsheet system for reporting and tracking the resolution of SCADA data problems related to the New England ICCP network
- Organization Name
  - ISO New England
- NERC Registration (e.g., reliability coordinator)
  - reliability coordinator
  - balancing authority
  - transmission operator
- Contact Name
  - Brock Nubile
- Contact's Official Title
  - Lead EMS Support Specialist
- Contact's Telephone Number
  - 413-540-4210
- Contact's E-mail Address
  - bnubile@iso-ne.com

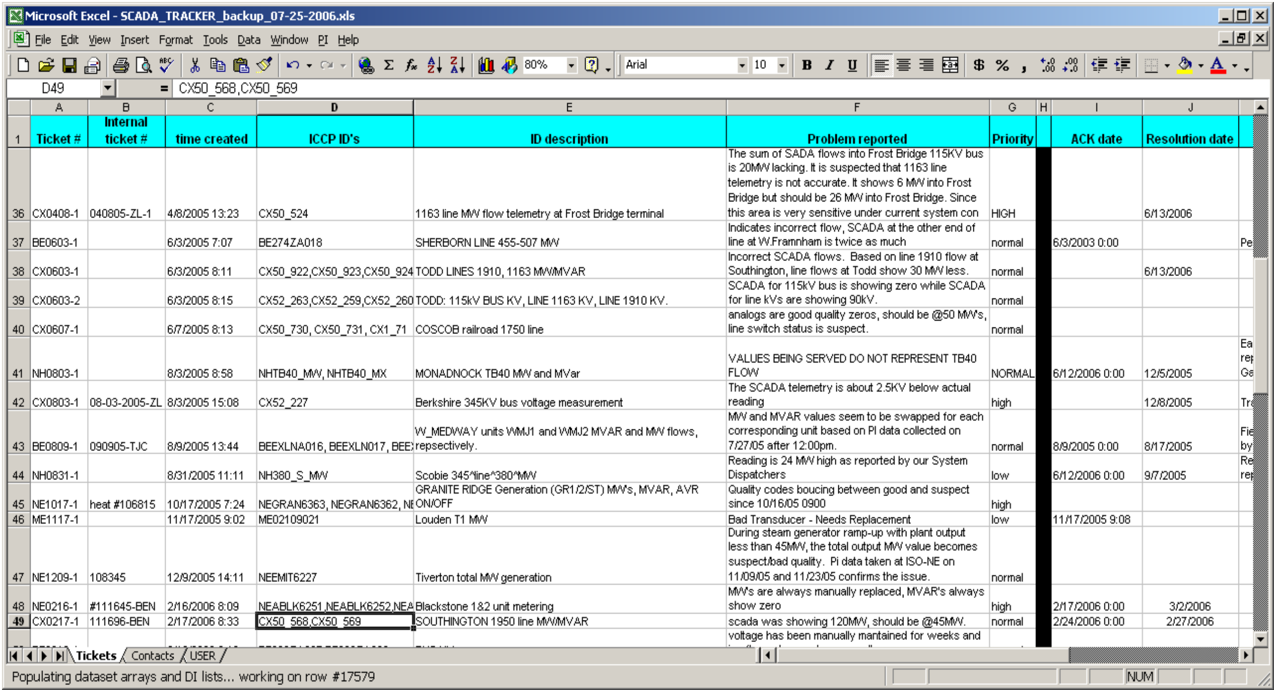
Description of the Tool/Practice

- What does it do?
  - Provides a standard format and procedures for creating trouble tickets related to ICCP SCADA data problems. The Excel spreadsheet contains the procedures, the tracking log, and a set of macros that automatically creates an e-mail message of the ticket to be sent to the appropriate transmission owner/SCADA site. This provides a mechanism for all sites on the network to report data problems that affect all sites on the network. It also provides a log to track resolution of all problems.
- Who uses it?
  - ISO and transmission owner/SCADA EMS support staff
- What are the inputs?

- o Detailed Information about the ICCP data ID with a description of the problem — ICCP ID, data owner, date, problem with the data, and priority rating

- What are the outputs?
  - o Spreadsheet tracking sheet, automatic e-mail message generated
- What is the user interface?
  - o Microsoft Excel spreadsheet; see screenshots below.
- What is/was the alternative practice?
  - o Individual e-mails or phone calls to IT personnel at each site





Microsoft Excel - SCADA_TRACKER_backup_07-25-2006.xls

Reliability/Situational Awareness

- How does it enhance reliability and/or situational awareness?
  - o Improves repair times for SCADA data by getting the appropriate information to the correct staff in a timely fashion
  - o Broadcasts trouble report to all transmission owner sites so all parties are aware of the problem
  - o Provides a tracking mechanism to identify the current status of a data problem and helps identify data values with repeated problem
- Which reliability standard(s) does it help meet or exceed?
  - o IRO-003
  - o IRO-005
  - o TOP-006
  - o TOP-005
  - o COM-001

Support and Maintenance Issues

- What did it take to implement?
  - o Group agreement to parameters and procedures, appropriate contact lists developed, minor macro programming within Excel
- What does it take to maintain?
  - o Enhancements to tool made upon request and review of ISO-NE's Data Communications Task Force
  - o Each submitter must update log with acknowledgment and resolution date

Examples of Excellence

EOE-3
Reference — Section 1.2, ICCP-Specific Data
Submitted by — ISO New England

Description

ISO New England and its transmission owners have implemented an automated monitoring system that periodically compares data set time stamps to detect and alarm any data sets that have stopped updating for any reason.

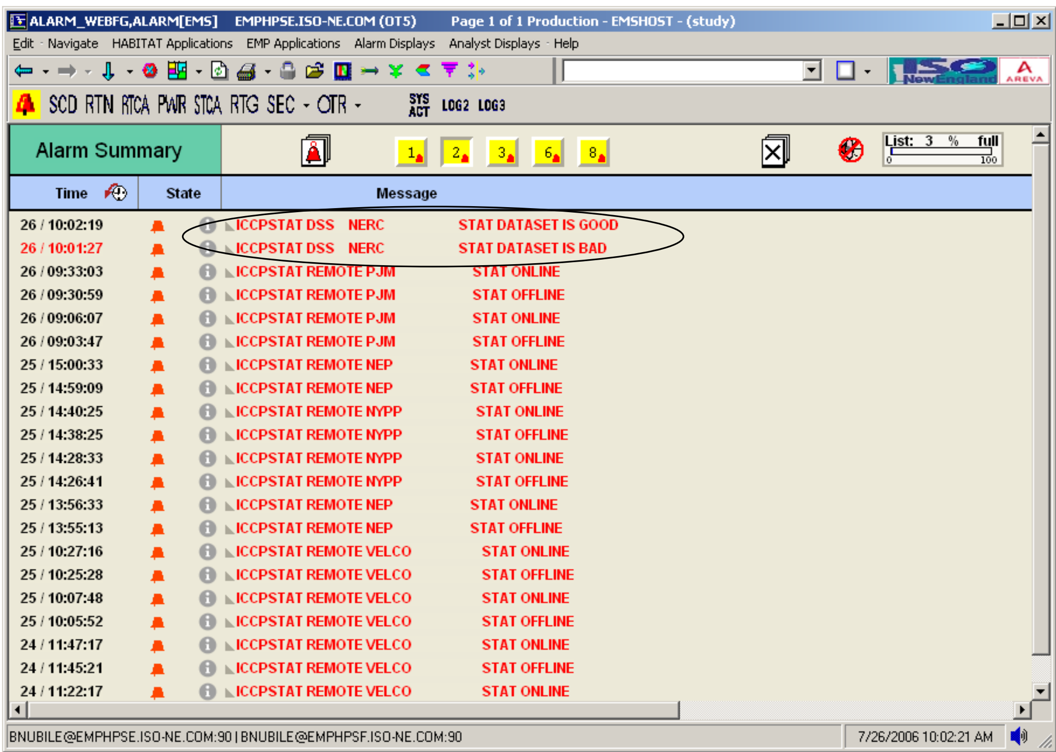
General Information

- Tool/Practice Name
  - DSMON (Data Set Monitor), an in-house designed and written PERL program that monitors all inbound and outbound ICCP server data sets on our vendor-based ICCP servers to confirm that they are transferring data
- Organization Name
  - ISO New England
- NERC Registration (e.g., reliability coordinator)
  - reliability coordinator
  - balancing authority
  - transmission operator
- Contact Name
  - Brock Nubile
- Contact's Official Title
  - Lead EMS Support Specialist
- Contact's Telephone Number
  - 413-540-4210
- Contact's E-mail Address
  - bnubile@iso-ne.com

Description of the Tool/Practice

- What does it do?
  - Every 90 seconds the program dumps a list of all ICCP data-base data sets and compares the last transfer set time to real time while accounting for the data-set transfer parameters. If delta exceeds a threshold, an alarm is issued to the operators on the EMS. This program detects and alarms any data sets that are interrupted because of:
    - Data-base modeling errors when remote sites perform updates (most common)
    - ICCP application software bugs, memory leaks, or extended run times
    - Severe network problems in which ICCP associations cycle frequently (a failed data set is usually the first symptom)

- Who uses it?
    - o Dispatchers and IT support staff
- What are the inputs?
    - o Vendor-based ICCP database, time-synchronized local ICCP server clock, user-entered run-time periodicity
- What are the outputs?
    - o GOOD/BAD status for each ICCP remote's data sets in the form of an ICCP server log file, vendor-based ICCP server data-base values, EMS-based operator alarms
- What is the user interface?
    - o Native EMS-based alarms
- What is/was the alternative practice?
    - o No alternative; this type of monitoring and alarming not offered by the vendor



Reliability/Situational Awareness

- How does it enhance reliability and/or situational awareness?
    - o Alerts operators and IT staff that large portions of data are not updating even though ICCPLINK is still connected and "UP"
    - o Allows IT staff to pursue correcting problem either locally or remotely
- Which reliability standard(s) does it help meet or exceed?
    - o IRO-003

    - IRO-005
    - TOP-005
    - TOP-006
    - COM-001

Support and Maintenance Issues

- What did it take to implement?
    - PERL programming, data-base additions on ICCP and EMS system, training for operators and support staff to respond to the new alarm
- What does it take to maintain?
    - No special maintenance required

Description

Tool/Practice Name:	Facilitated Transaction Checkout (FTC)
NERC Registration:	Reliability Coordinator
Contact Name:	John M. Simonelli
Contact's Official Title:	Manager Operations Support Services
Contact's Telephone Number:	(413)535-4157

Overview

Historically, the accuracy associated with transaction checkout between those entities tasked with maintaining reliability has been an important industry issue as recognized by both the NERC Operating Committee and its Interchange Subcommittee. In recognition of the reliability concerns associated with transaction checkout and findings from the August 2003 Blackout, elected to undertake a region-wide effort towards improving transaction accuracy.

The NPCC FTC is a tool implemented by all balancing authorities within the NPCC region. PJM expects to implement FTC in the near future, and MISO expects to implement FTC during the fourth quarter of 2006. The tool is a message structure that enables neighboring reliability entities to query each other's transaction stacks and perform an automated comparison prior to performing verbal checkout. This is accomplished through programmatic data exchange using a standard set of protocols agreed to by the NPCC reliability entities. Because the tool is the communication behind the display, the results can be seamlessly integrated into existing EMS applications. The FTC process provides for the data to be easily integrated into existing displays to meet the unique needs of the different balancing authority operators. FTC does not require third-party intervention or support. The current real-time transaction checkout implementation focuses on transactions between entities using the required NERC e-tag as a common identifier. With slight variations to the standard message structure, the tool can and, in some current instances, is being used for Day Ahead/Day Prior transaction verification, after the fact schedule reconciliation, actual tie information and metered tie flow information for inadvertent checkout.

Detailed Description

Transaction Checkout is a common term for an inter-regional business process employed by neighboring BA operators in the northeast. During the Transaction Checkout process, neighboring BAs communicate in an effort to reconcile the pending net interchange between the individual BAs. The primary objective of the Transaction Checkout process is to reach agreement on a net interchange between BAs as well as the underlying list of individual transactions for the next hour. These transactions may be derived under the auspices of full financial markets or under the traditional physical bi-lateral systems. In either case, operators must cross-reference the transactions scheduled separately by each BA to ensure that for each transaction scheduled out of a given BA, there is a corresponding transaction scheduled into the neighboring BA.

For the majority of the industry, this is currently a manual business process accomplished via telephone communication by BA operators. Moreover, each operator has extremely limited (if any) visibility of other BA transactions. Cycling through lists of transactions and cross-referencing them with the neighboring BAs (ensuring that both sides have the same information) is a lengthy and labor-intensive process. Since the operator of one BA does not have any visibility into the other BA's transaction stack, the operator must review each transaction to ensure that it matches the transactions expected in the neighboring BA. Currently, operators must repeat this tedious and inefficient process every hour, 24 hours per day, 7 days per week. Moreover, with the recent efforts to reduce bidding and scheduling to 15-minute intervals, the current process may prove unsustainable.

Facilitated Transaction Checkout (FTC) is accomplished through programmatic data exchange using a standard set of protocols agreed to by the NPCC balancing authorities (BA). Each BA is responsible for providing a “service” that allows other BAs to programmatically request and receive transaction data in preparation for checkout procedures. It is important to point out that there is no standard FTC application or user interface. Each BA has the flexibility to incorporate the functionality into their existing BA tools as each sees fit.

The NPCC FTC solution provides tangible efficiency gains in the transaction checkout process. Advancing this solution from a concept to implementation required mutual cooperation and collaboration from neighboring Balancing Authorities in the northeast. Continued collaboration among NPCC members and its neighbors, PJM and MISO, was vitally important to collectively define, develop, and implement a robust FTC solution.

The proposed FTC solution is not intended to fully automate the process of checkout, nor is it aimed at eliminating the critical human function of the operator. Instead, it is designed to assist system operators by equipping them with the most complete, accurate and timely data possible. The purpose is to facilitate the checkout process such that it can be accomplished in less time and with greater accuracy. The fundamental high-level business process of reviewing transactions between BAs will remain the same; the FTC solution simply makes it easier to execute.

Looking beyond the implementation of FTC in the northeast, an additional direct and tangible benefit of the FTC effort has been programmatic flexibility. The technology developed to support FTC is now serving as the foundation in the development of several other NPCC-wide applications, such as after the fact Inadvertent Accounting and real-time tracking of Shared Activated Reserves. NPCC's development of new, automated "wide-area" tools continues to improve operator efficiency and overall system reliability.

Examples of Excellence

EOE-5
Reference — Section 2.2, Visualization Techniques
Submitted by — Southwest Power Pool (SPP)

Description

Tool/Practice Name:	PowerWorld Retriever
NERC Registration:	Reliability Coordinator
Contact Name:	Kevin Bates
Contact's Official Title:	EMS Engineer
Contact's Telephone Number:	(501)614-3288
Contact's E-mail Address:	kbates@spp.org

Overview

Southwest Power Pool utilizes PowerWorld Retriever to provide a system overview as well as alarm using pie charts and flashing lines. The contouring of voltage, state estimator versus SCADA, generation MW and Mvar availability has proven to be useful in reliability coordination as well as system performance from a technical staff perspective.

PowerWorld Retriever provides a geographical overview of the SPP Reliability system and its neighboring areas. Visualization effects include:

- Arrows depict direction and magnitude of line flow
- "Blinking" lines indicate real-time out-of-service elements
- Pie charts alarm for real-time overloads
- Voltage is contoured

Detailed Description

RCs use PowerWorld Retriever as a situational awareness tool in real-time operations as well as training situations. EMS engineers have also used PowerWorld Retriever for contouring differences between SCADA and the state estimator. Since the PowerWorld Retriever model is derived from the EMS model, PowerWorld Retriever has also been used for model verification.

The PowerWorld Retriever model is constructed using the EMS NETMOM model exported via the EMS modeling tool, Genesys. Programs residing on the EMS export SCADA data every 30 seconds and state estimator data every 1 minute from the EMS to text files. Because real-time status for elements is not available from all sources via ICCP, these elements (lines, transformers, generators) have real-time status points defined using real-time status of associated breakers and switches. These points and analogs are placed in flat text files along with a unique alias that identifies a value in the PowerWorld Retriever model. Configuration files loaded to PowerWorld Retriever upon initialization include subscriptions that provide the “links” between these aliases and the PowerWorld Retriever model data fields. These text files can be generated from any EMS system (production, backup, development, etc.), so PowerWorld Retriever can be utilized in training scenarios as well.

No data outputs are generated by PowerWorld Retriever other than update logs. The data inputs to the model are displayed on associated one-lines which may be geographic or schematic. The aforementioned features (blinking lines, line flow arrows, etc.) are displayed on one-lines that are associated with the underlying model. The text file inputs can be configured to link to any EMS system, therefore resulting in displays showing data from systems used for production, training, or testing.

The interface is typical pull-down menus and toolbars. The most common features used by RCs include navigation tools such as zoom, pan, find, etc. Because of the vast options available, saved views are used to easily navigate between desired displayed data on one-lines. These views have position and layers turned on/off so users are one click from desired views. Case Information tables provide model information and options for sorting, filtering, and exporting. Some substation one-lines are available.

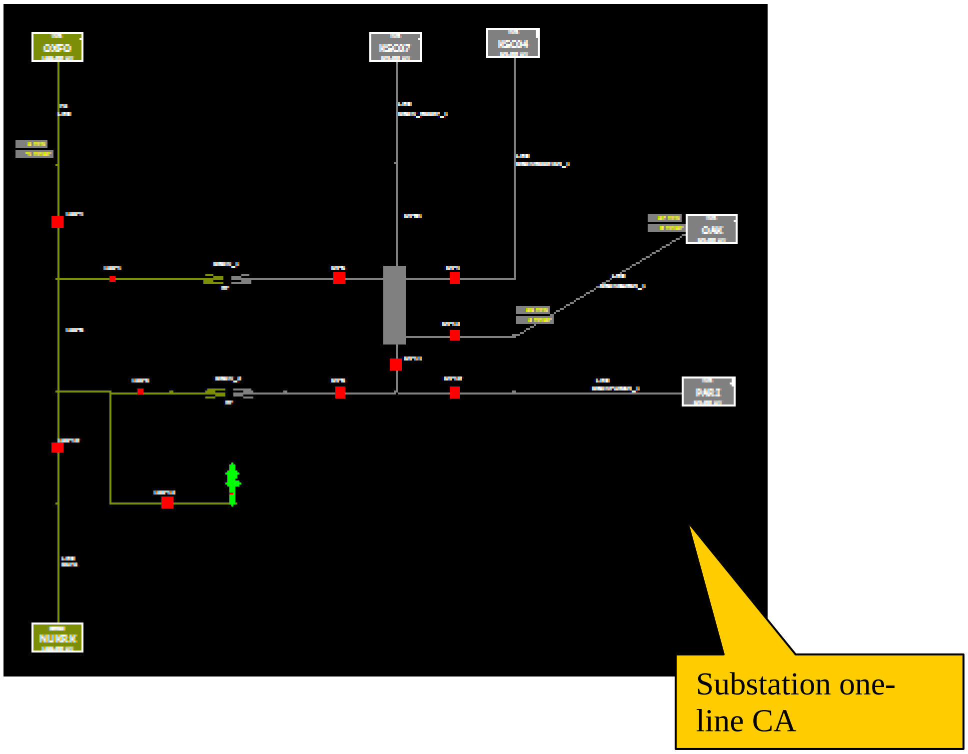
1.000 pu
0.900 pu
Bad quality data
Possible alarm
Voltage Contour view



All data displayed in PowerWorld Retriever are available using EMS displays. They are not depicted in a geographic overview but rather a bus/branch or tabular list. With this tool, RCs are made aware of voltage conditions, real-time flows, and outages for the SPP Region and adjacent regions, which enhances their situational awareness. PowerWorld Retriever helps SPP meet Standard IRO-003-0 by providing a wide-area view of the SPP RC Area and the areas of neighboring RCs.

PowerWorld Corporation was contracted to develop the initial model and overview one-line. SPP and PowerWorld staff integrated an export of the SPP EMS model to the PowerWorld Retriever model structure. Also developed with cooperation of PowerWorld staff were alias and subscription formats used in linking data from the EMS to the PowerWorld Retriever model. SPP also developed programs to export SCADA, state estimator, real-time contingency analysis, and outage scheduler data into text files for uploading to PowerWorld Retriever. Some clean-up and customization of the overview one-line was performed as well as of the view definitions.

Maintenance is performed with each upload of a new EMS model or as needed for modeling corrections. Text files with pertinent modeling information are exported using Genesys. Because PowerWorld Retriever's model structure uses bus numbers that do not correlate with a bus number from the EMS model, a Microsoft Access database is used to maintain consistency between models. This prevents renumbering of one-lines during bulk uploads of a new model. Only new or deleted devices need addressed on associated one-lines. This database also allows for export of aliases and subscriptions used for compiling configuration files used by PowerWorld Retriever.

Examples of Excellence

Submitted by — Midwest ISO

Description

Tool/Practice Name: Wide-Area Overview
NERC Registration: Reliability Coordinator

Overview

MISO implemented an expansive wide-area overview display with underlying BA and one-line displays. MISO also incorporated the following into its visualization tools:

- A flowgate monitoring tool that uses LODFs calculated every 10 seconds. This display also includes a provision for dynamic ratings or operating guides.
- A set of reactive monitoring display "delta" tools that visualize sudden changes in generator output or transmission facility flow.

Examples of Excellence

EOE-7
Reference — Section 2.2, Visualization Techniques
Submitted by — American Transmission Company

Description

Tool/Practice Name: Wide-Area Overview
NERC Registration: Reliability Coordinator

Overview

ATC utilizes an application that interfaces directly with its EMS to provide system operators with a dynamic wide-area overview of ATC's network topology as well as state estimation of the neighboring systems. The one-line display (wide-area overview representation) is created automatically from the data within the network model (internal and external). When new equipment is added, the wide-area overview display automatically updates. The wide-area overview provides the operator with actual flows, indications of open lines, and visual indication for lines approaching thermal limits. ATC's operators can dynamically select what is displayed, zoom in or out, and pan across the system. In addition to displaying a wide-area overview, system operators can filter, sort, and query the data to better analyze the power system.

Examples of Excellence

EOE-8
Reference — Section 2.5, State Estimator
Submitted by — Midwest ISO

Description

Tool/Practice Name: State Estimator
NERC Registration: Reliability Coordinator

Overview

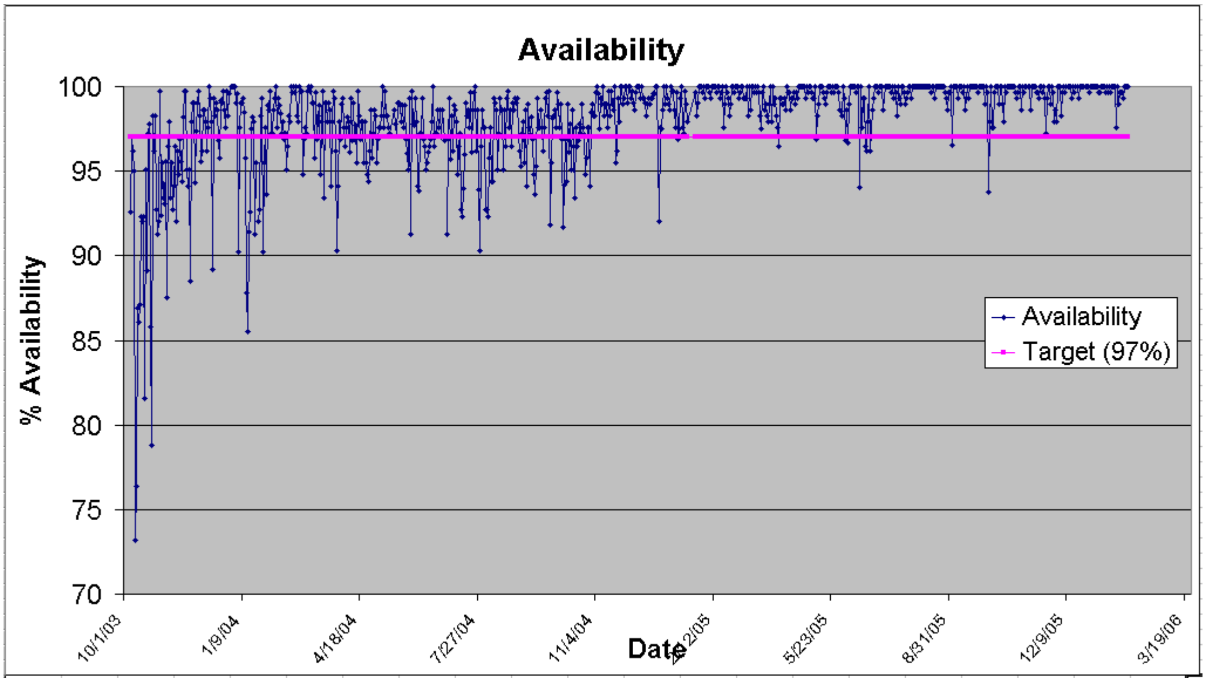
MISO has developed a state estimator solution summary spreadsheet that is used to track solution availability and solution-quality metrics such as solution mismatch, status, convergence, and error tracking for select branch flows, bus voltages, and tie-line flows.

Detailed Description

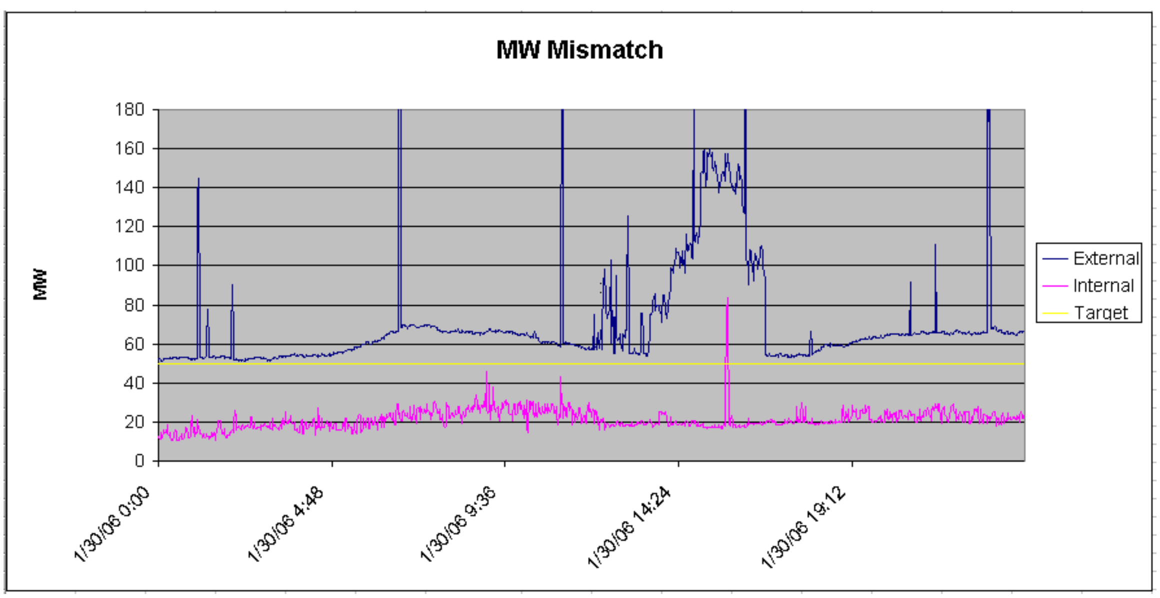
The "home page" of the summary is shown below and includes explanations of what each metric represents.

SE Solution Summary	**01-30-2006** **12:00:00 AM - 11:59:59 PM** Import Data Into Spreadsheet	
State Estimator Metrics Plots	**Plot Explanation**	
State Estimator Availability	**MISO and Transmission Owners require 97% availability. This metric describes the number of 5 minute periods in a day that had a state estimator solution. In a day there exists 288 5 minute periods, to reach 97% availability MISO needs to have state estimator solutions for 280 or more of those periods.**	SE Availability Plot
State Estimator Solution Mismatch	**MISO and Transmission Owners require < 50 MW mismatch for all companies within the MISO footprint. The mismatch data reported here illustrates solution mismatch for both internal and external companies.**	SE MW Mismatch Plot
State Estimator Solution Status	**Illustrates the solution status for each 5 minute period over a 24 hour period. A point of "1" indicates a valid solution period. A point of "0" indicates that no valid solution occurred during that five minute period.**	SE Solution Status Plot
State Estimator Voltage Convergence	**MISO tracks the state estimator voltage convergence on a solution basis. MISO and the Transmission Owners require the state estimator to run with voltage and/or angle convergence tolerances of 0.002, and maximum MW mismatch of 50 MW.**	Voltage Convergence
50 Flowgate, 10 Tie Line, 30 Bus Metrics	**MISO monitors a list of 50 flowgates, 10 external tie lines, and 30 critical bus voltages. These plots illustrate the % error of the solved value compared to the measured**	50 Flowgate, 10 Tie Line, 30 Bus Metrics

The SE availability plot is shown below. It reveals a dramatic increase in the availability of the state estimator as MISO made preparations for the opening of the market. Market applications depend on accurate and highly available solutions from the state estimator to support locational marginal pricing and congestion management.



The MW mismatch plot shown below illustrates how well the total mismatch for companies within the MISO footprint is kept within the target value.



The availability and solution quality metrics illustrated above as well as others that MISO has developed are excellent examples of the types of state-estimator performance metrics that should be monitored as part of the pilot program recommended above. MISO has clearly demonstrated that it is desirable and practical to develop such metrics.

EOE-9
Reference — Section 2.6, Contingency Analysis
Submitted by — Entergy Corporation

Description

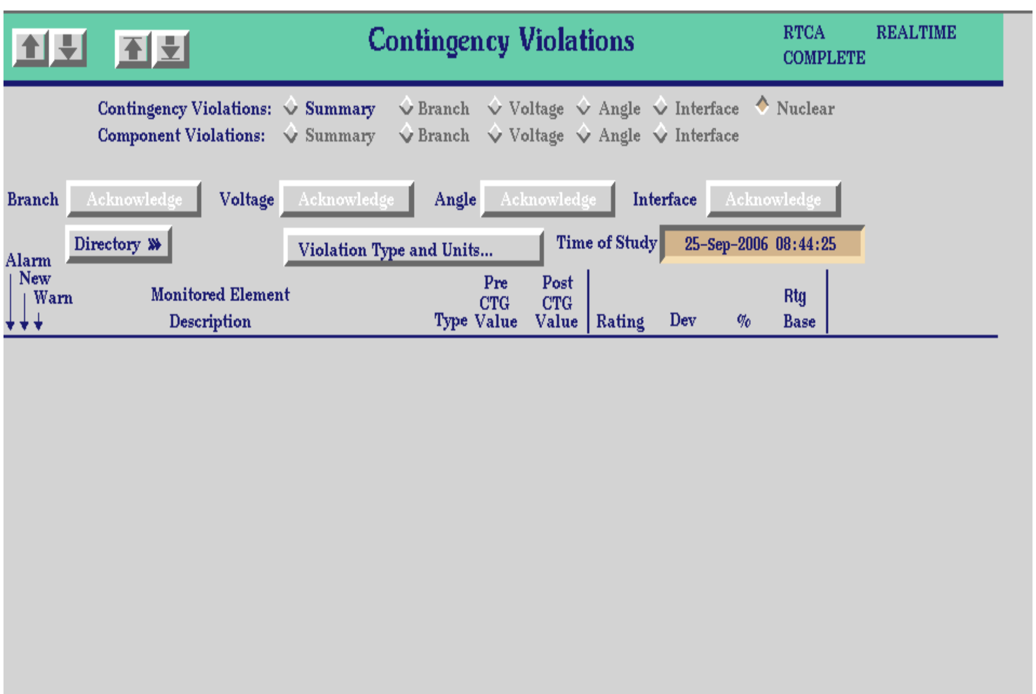
Tool/Practice Name	Utilization of RTCA in Nuclear Offsite Power Monitoring
NERC Registration	Reliability Coordinator, Transmission Operator, Balancing Authority

Overview

Entergy has a real-time contingency analysis application that accurately simulates the effects of loss of a nuclear power plant on switchyard voltage.

Detailed Description

The loss of a nuclear power plant results in the station service load being completely fed by offsite power. To simulate these events accurately, Entergy modified the contingency definitions to add plant load in the event of NPP trip. The real-time contingency analysis at Entergy's control center simulates approximately 1,700 contingencies. To isolate the violations related to NPP offsite power, Entergy also created a separate display that only shows the NPP violations. The following screenshot shows the customized display.



Entergy also developed detailed procedures and operating guides for reporting and acting on NPP offsite power violations. The procedures are summarized below:

Steps to Responding to Violations

Steps 1–3 should be performed within 30 minutes.

1. Verify the validity of the Real-Time Alarm or Post-Contingent Violation.
   a. It is extremely important that all violations are validated prior to continuing with this process.
2. Create State Estimator (RTNET) Save Case to document the violation. The case name should be: “Nuclear_Violation_mm_dd_yyyy_hh_mm”

3. Check the state of the transmission grid for a possible mitigation plan.
   a. Determine if there are any capacitors or reactors in the area that would help relieve the violation.
   b. Determine if there are any transmission equipment outages in the area that are having an impact on the violation.
   c. Determine if there are any generators (Other than the Nuclear Generator) that can be utilized to help relieve the violation. ***The Nuclear Generator can be called to assist with relieving HIGH Voltage, but should NOT be utilized to relieve LOW Voltage.
4. Develop and execute the mitigation plan. This mitigation plan should be capable of relieving the violation without having a negative affect on the reliability of the transmission system. Steps 1-3 must be completed within 30 minutes following the violation.
5. Report the violation to the respective nuclear plant using the following form (Regardless of whether or not the mitigation plan corrected the violation).

   This form should be faxed to the respective nuclear plant and followed up with a phone call to verify the receipt of the fax.

6. If the violation was NOT corrected, proceed to step 7. If the violation WAS corrected no further action will be required. However, be prepared to answer questions from nuclear personnel regarding the violation.

   Fax updated Online Notification Form to the Respective Nuclear Plants and follow up with a phone call to verify the receipt of the fax.

7. If the mitigation plan fails to relieve the violation within 30 minutes or a mitigation plan could not be determined within 30 minutes, contact the on-call support personnel, on-call Duty Chief and the Reliability Coordinator to make them aware of the situation.

   Fax updated Online Notification Form to the Respective Nuclear Plants and follow up with a phone call to verify the receipt of the fax.

8. **Nuclear Conference Call:** If a violation still exists, the nuclear plant will set up a conference call with nuclear and transmission. Once the system operation center (SOC) has been notified of the conference call time by nuclear, the SOC Shift Supervisor will be responsible for notifying the following transmission personnel of the conference call. ***To notify this group you will need to send a page to the "Nuclear Notification" Group using the following text: ***Name, Phone Number***. Nuclear Offsite Voltage Notification made on ***mm/dd/yyyy*** at ***HH:MM***. Conference call will begin at ***HH:MM***. Phone Number: **###-###-####**. Access Number: **#####**

    - Transmission Operational Planning Representative
    - SOC Duty Chief
    - Operations Director
    - System Security - Manager
    - Reliability Coordinator
    - Reliability Coordinator Support
    - TOC Manager for area of discussion

9. Following the conference call, the SOC Shift Supervisor will be responsible for the execution of any additional transmission actions as well as continuing to monitor the violation.

    Fax updated Online Notification Form to the Respective Nuclear Plants and follow up with a phone call to verify the receipt of the fax.

10. Once the violation has ended, the SOC Shift Supervisor will be responsible for sending the nuclear plant the completed Nuclear Notification form and notifying all transmission personnel involved of the end of the violation.

    The form should be faxed to the respective nuclear plant and followed up with a phone call to verify the receipt of the fax.

11. Create State Estimator (RTNET) Save Case to document the violation. The case name should be: "Nuclear_Violation_mm_dd_yyyy_hh_mm"

The process also requires operators to monitor availability of real-time contingency analysis and the state estimator. Entergy also established a procedure to notify nuclear power producers in the event of unavailability of real-time contingency analysis or the state Estimator. The procedure is outlined below. These procedures are only applicable for notifying nuclear plants.

Steps to take when the state estimator is unavailable:

1. Document the time that the state estimator became unavailable. Report the unavailability to EMS on call person.
2. Can the state estimator be restored in <1 Hour?

a. **YES:** Continue to monitor on how long the state estimator has been down. If the restoration time exceeds 1 Hour, proceed to step 2b.
b. **NO:**
    i. Contact the on-call Operations representative.
        1. Verify that the Offline Nuclear Monitoring System is available.
        2. Discuss any unplanned system changes that have occurred since the last time Operations ran the nuclear offline study.[8] If changes have occurred, request that Operations rerun the nuclear study to check for any issues.
    ii. Verify that the SOC EMS system is functioning.
        1. **If SOC EMS System is <u>NOT</u> functioning:** Contact each Transmission Operation Center (TOC) that has a nuclear plant within its system and request that it notify the SOC if any low-voltage alarms are received at any substation near the nuclear plant. Proceed to iii.
        2. **If SOC EMS System <u>IS</u> functioning:** Continuing to monitor for any nuclear voltage alarms. Proceed to iii.
    iii. Notify each nuclear plant using the following form.

        This form should be faxed to the respective nuclear plant and followed up with a phone call to verify the receipt of the fax.

3. After the state estimator has retuned to service and the SOC EMS is functioning correctly.
    a. If the nuclear plants were previously contacted in the above step, notify each nuclear plant using the same form as above.

        The form should be faxed to the respective nuclear plant and followed up with a phone call to verify the receipt of the fax.

    b. If the SOC EMS System was not functioning correctly and the TOCs were requested to monitor real-time voltage alarms around the nuclear plants, contact the TOCs and inform them that the SOC EMS System is now functioning correctly.

[8] Entergy has also implemented an offline process to monitor the nuclear power plant offsite power for next day.

EOE-10
Reference — Section 2.7, Critical Facility Loading Assessment
Submitted by — PJM

Description

Tool/Practice Name: Thermal Tracking
NERC Registration: Reliability Coordinator

Overview

The Thermal Tracking (TT) critical facility loading assessment nominated by PJM was originally supplied as a standard part of their EMS vendor software but has been subsequently enhanced by PJM. TT is used to screen for transfer interface violations and a number of potentially serious double-contingency violations. Of particular value is the enhanced capability for this application to advise operators of the generation redispatch options to alleviate reported overloads. This tool also acts as a backup should the first-line security analysis functions abort or otherwise degrade.

Examples of Excellence

EOE-11
Reference — Section 2.9, Study Real-Time Maintenance (SRTM)
Submitted by — PJM

Description

Tool/Practice Name: Study Real-Time Maintenance
NERC Registration: Reliability Coordinator

Overview

PJM Regional Transmission Operator (RTOP) can host up to three users of the SRTM function simultaneously in the production EMS environment. The function is typically performed by support staff, not operators. To avoid conflicts, each user of the SRTM function is completely independent of the production real-time system and of any other SRTM users. Each SRTM user interface looks and feels exactly like the production network applications. However, instead of the red window border used to indicate the production real-time system, a green window border is used to clearly distinguish that the user is actually in SRTM mode.

Historical real-time state estimator saved cases are archived automatically every 5 minutes. All non-converged state estimator solutions are archived automatically when they occur. An SRTM user can be initialized from a historical saved case or the current real-time state estimator solution within seconds. All real-time network applications including NTP, CFLA, flowgate distribution factor calculation, state estimator, contingency analysis, and voltage stability are initialized from the saved case or the current real-time solution. All real-time network applications can be run exactly as they were in the real-time production EMS environment; therefore, all problems and results can be reproduced for debugging purposes. An SRTM case can be archived by the user and retrieved at a later time to complete work. An SRTM case can be used to initialize a study power-flow user, in the same manner as from a real-time state estimator case, to simulate the study network applications.

It is important to note that an old case archived from a previous version of the network model may not be compatible with the current version of the network model depending on the number and type of model changes. To avoid this problem, PJM debugs problems as soon as possible after they occur and prior to updating the network model on the production system if possible. If the model has to be updated prior to resolving a problem, the case is used on a non-production EMS system with the previous version of the network model to complete the work. The PJM practice is to debug and resolve all non-converged state estimator solutions, all non-converged contingency analysis solutions, and all non-converged voltage stability solutions using SRTM as quickly as possible.

In addition, any other network application problems identified by PJM staff are debugged and resolved as quickly as possible using SRTM.

SRTM allows PJM to quickly and easily recreate, debug, and resolve network application problems without impacting the real-time network applications and has increased the overall availability of the real-time network applications. The PJM SRTM was provided by the PJM EMS vendor with some customization. Significant initial testing was required to insure that the initialization software was operating correctly to insure that SRTM results exactly matched the production system. The PJM EMS network applications support staff are the primary users of the SRTM. The PJM system operators, reliability engineers and other engineering support staff also use the SRTM. Because SRTM is fully integrated with the production EMS system, it requires little additional maintenance.

EOE-13

Reference — Section 2.14, Other Tools (Current and Operational)
Submitted by — Bonneville Power Administration

Description

Tool/Practice Name:	Congestion Management Application
NERC Registration:	Balancing Authority, Transmission Operator

Overview

The Bonneville Power Administration (BPAT) uses a curtailment wizard in its implementation of a congestion management application. This wizard is an effective and key component of BPAT's congestion management tool for the interties. Schedule adjustments are communicated and coordinated among the affected parties via the e-tag. For the network, BPAT has an "interim" curtailment calculator, which targets specific generation and loads. This curtailment calculator can be used on two of the network flowgates. This is an "in-hour" tool and it works effectively by targeting specific generators and loads. However, it lacks a prospective view of upcoming flows and does not support preventing transmission sales that would further exacerbate the congestion. BPAT is currently planning to integrate e-tag curtailments with these "interim" curtailment calculators while pursuing tools to provide a full capability to manage capacities and congestion on their network.

Examples of Excellence

EOE-14
Reference — Section 2.14, Other Tools (Current and Operational)
Submitted by — FirstEnergy (FE) and MISO

Description

Tool/Practice Name:	Real Power-Voltage Stability Analysis Tool
NERC Registration:	Reliability Coordinator, Transmission Operator

Overview

Excerpted from survey comments by an FE representative:

> An operator must maintain an awareness at all times of where the system is operating relative to all limits. FE, in conjunction with the Midwest Independent Transmission System Operator (MISO), utilizes a real power-voltage (P-V) stability analysis tool that determines system operating limits in three critical areas of the FE transmission system. NERC commended the FE/MISO approach to voltage stability analyses as an Example of Excellence in their November 2, 2005 Reliability Readiness Audit and Improvement Program**.**
>
> P-V analysis is used to determine the health of the system by determining the rate of voltage decay at a system bus as the level of real power changes due to system loads or transfers across the system. The "nose" of the P-V curve represents the maximum real power load that can be served or the amount of power that can be transferred beyond which the rate of voltage decay dramatically increases toward voltage collapse. The difference between the real power quantity being monitored in real time and the real power limit at the nose of the curve is the real power operating margin. The MISO reliability coordinators and FE transmission operators monitor the flow on the three critical interfaces in real time to the lower of the voltage collapse limit, the steady-state voltage limit, and the thermal ratings limit. To provide a sufficient operating margin, MISO and FE apply a ten percent power flow safety margin in the next-day analysis and a five percent margin for the current-day analysis in determining the voltage collapse limit the operators will use. Additional analysis is conducted any time a critical facility in the FE area is out of service. For forced or emergency outages, a MISO operations engineer position is staffed around the clock to perform the analysis.

EOE-15
Reference — Section 3.5, Load-Shed Capability
Submitted by — Dominion Virginia Power

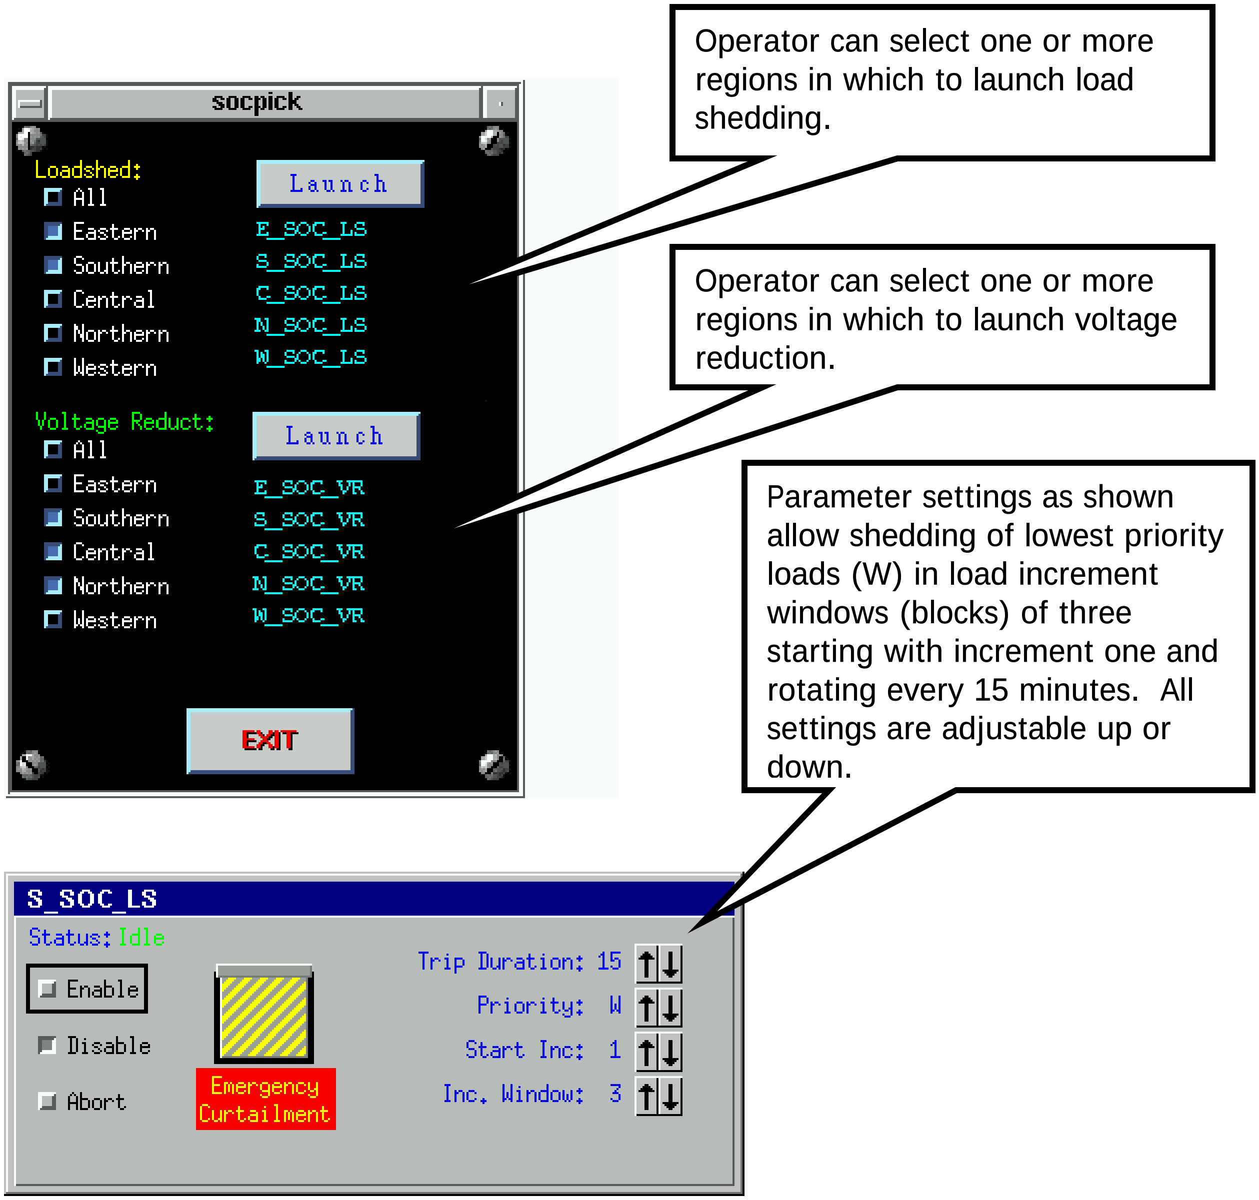
Description

Tool/Practice Name:	Load Shedding/Rotation and Voltage Reduction
NERC Registration:	Transmission Operator

Overview

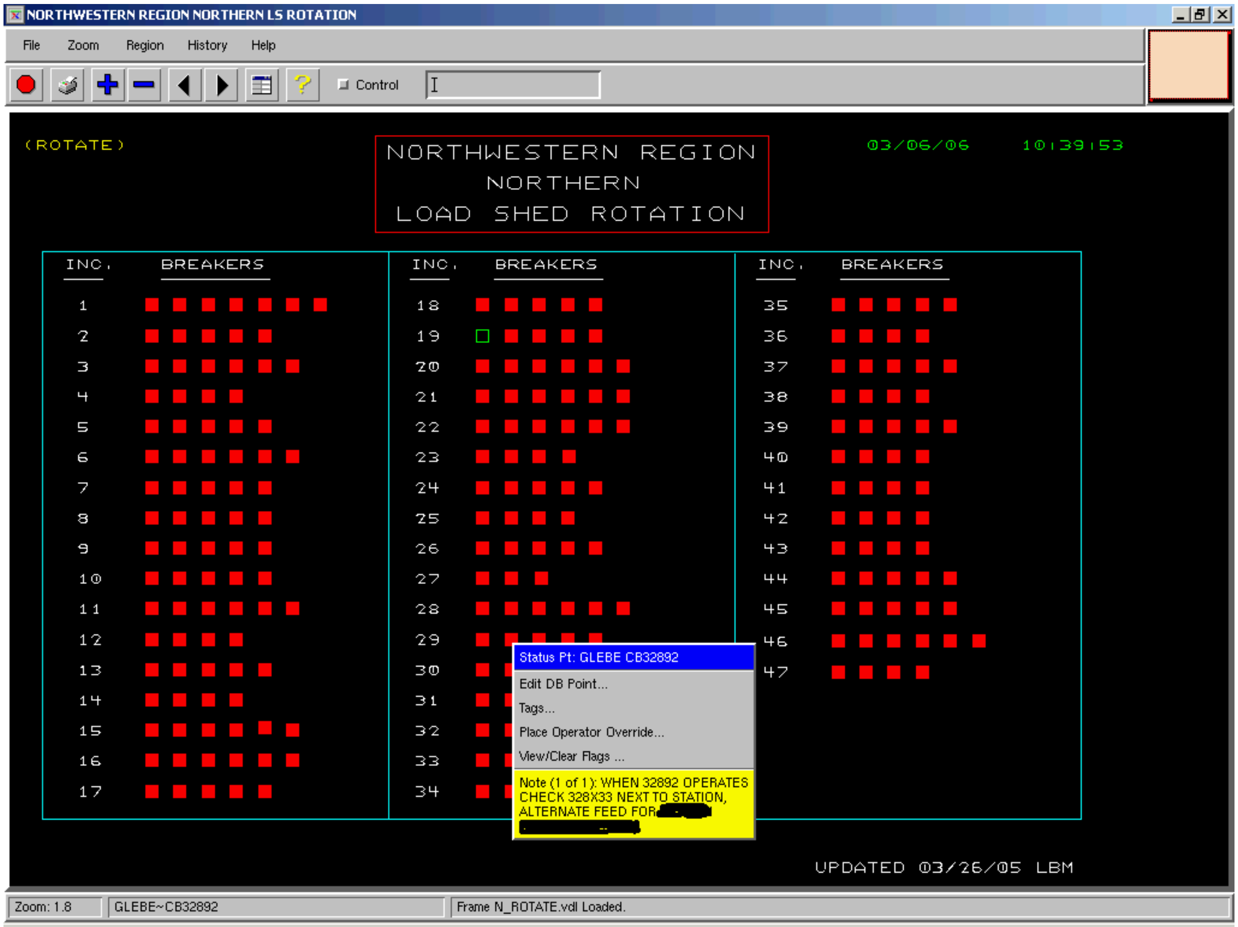
In order to quickly activate the Dominion Virginia Power Load Curtailment Plan, a control application was developed by Dominion to implement load shedding/rotation and voltage reduction. This application runs on the Distribution Management System (DMS), which was developed in house. The application is available to the transmission system operators at the SOC and is also available to the operators at the regional Distribution Operations Centers (DOCs). The program that allows the SOC to implement load curtailment is called SOCpick, and the program that allows the DOC to implement load curtailment is called Loadpick. The main difference between the two programs is the operator interface.

The transmission system operators at the SOC are responsible for implementing load shedding and voltage reduction at the direction of the RC. They can perform this function from their user interface at the SOC or they can request assistance from the regional operators in the three DOCs. The following screen shots show the SOCpick user interface for launching a system-wide or regional load-shed operation or voltage reduction and the user interface for adjusting the load-shed program parameters including trip duration, load priority (W — the lowest, X, Y, or Z — the highest), starting load increment, and load increment window.

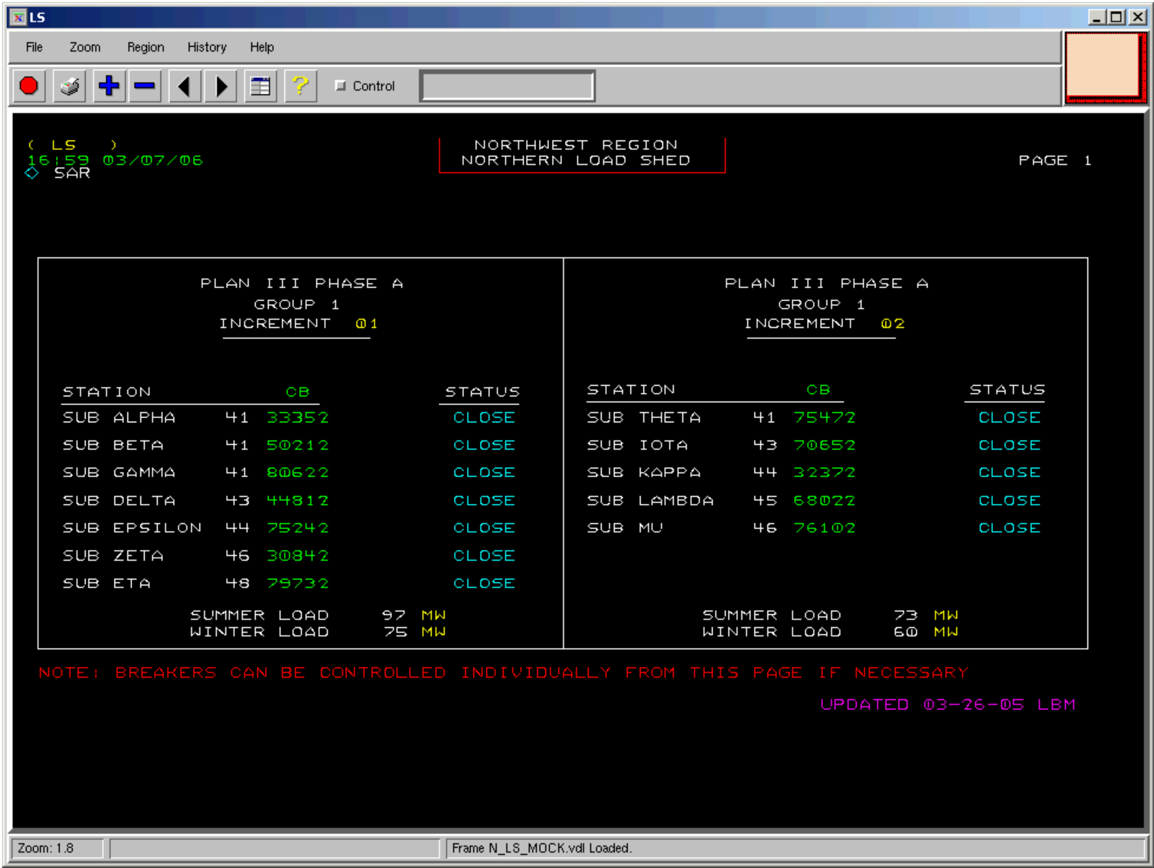


The following screen shot shows the status of each distribution breaker in each load-shed increment (block) in the northwestern region. There are a total of 47 increments in this particular region. In addition to showing the open/close (green/red) status of each breaker, placing the cursor over the breaker symbol generates a pop-up window that identifies the associated substation, breaker number, and other specific information related to the status of the circuit. Any breaker that has a tag on it will have a “T” appear next to it on this screen, and any breaker with a special note associated with it with will have an “N” appear next to it. In the example below, the “N” next to the breaker for circuit 32892 at the Glebe substation is obscured by the pop-up window that identifies the breaker. The pop-up also includes an operating note (redacted for security reasons) highlighted in yellow.

Not only can the status of individual circuits be monitored at any time from this screen, but once load shed is implemented, the progress of load-shed rotation can be monitored as well.

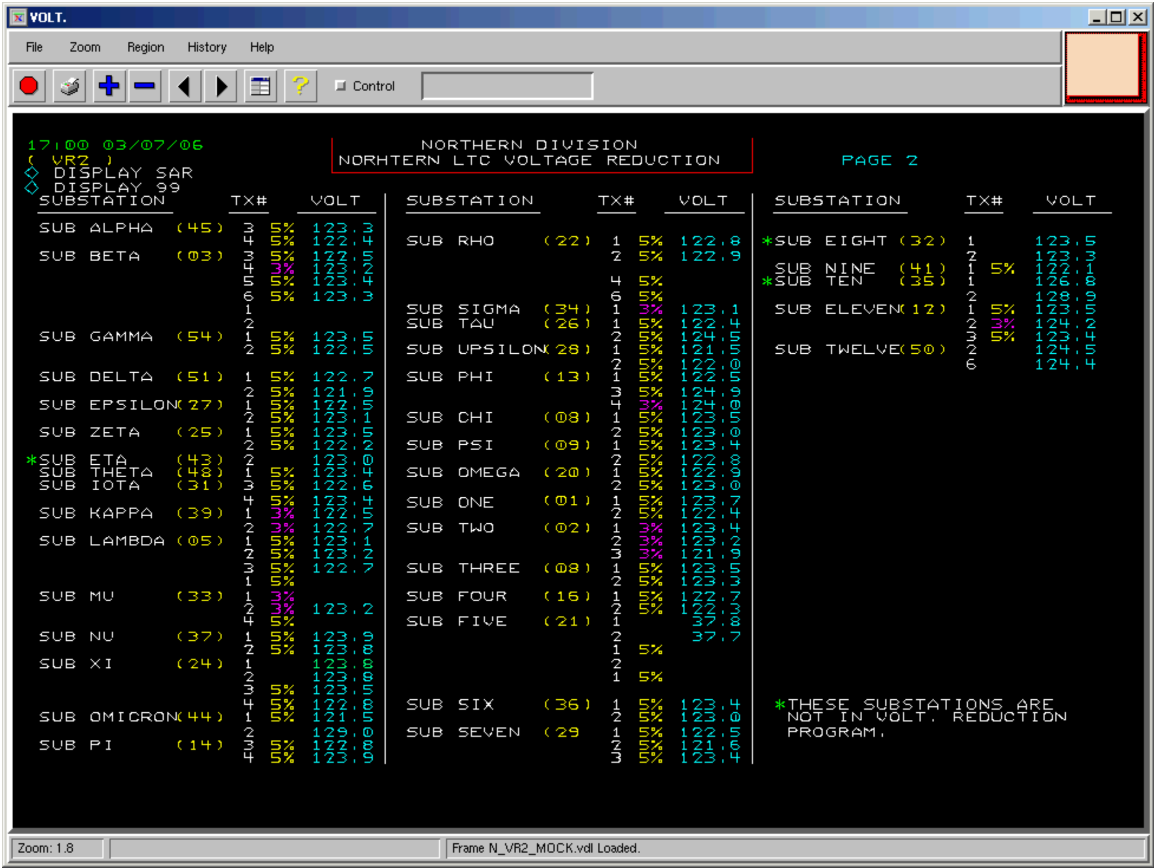


The next example screen shows another view of the individual circuits in the load-shed increments. The circuits that are part of increments 1 and 2 in the northwestern region are shown on this page along with their status and the substations in which they are located. The actual substation names have been replaced with aliases for security reasons. Also shown is the estimated load in each increment that is subject to being shed. These load estimates are based upon historical seasonal peaks.

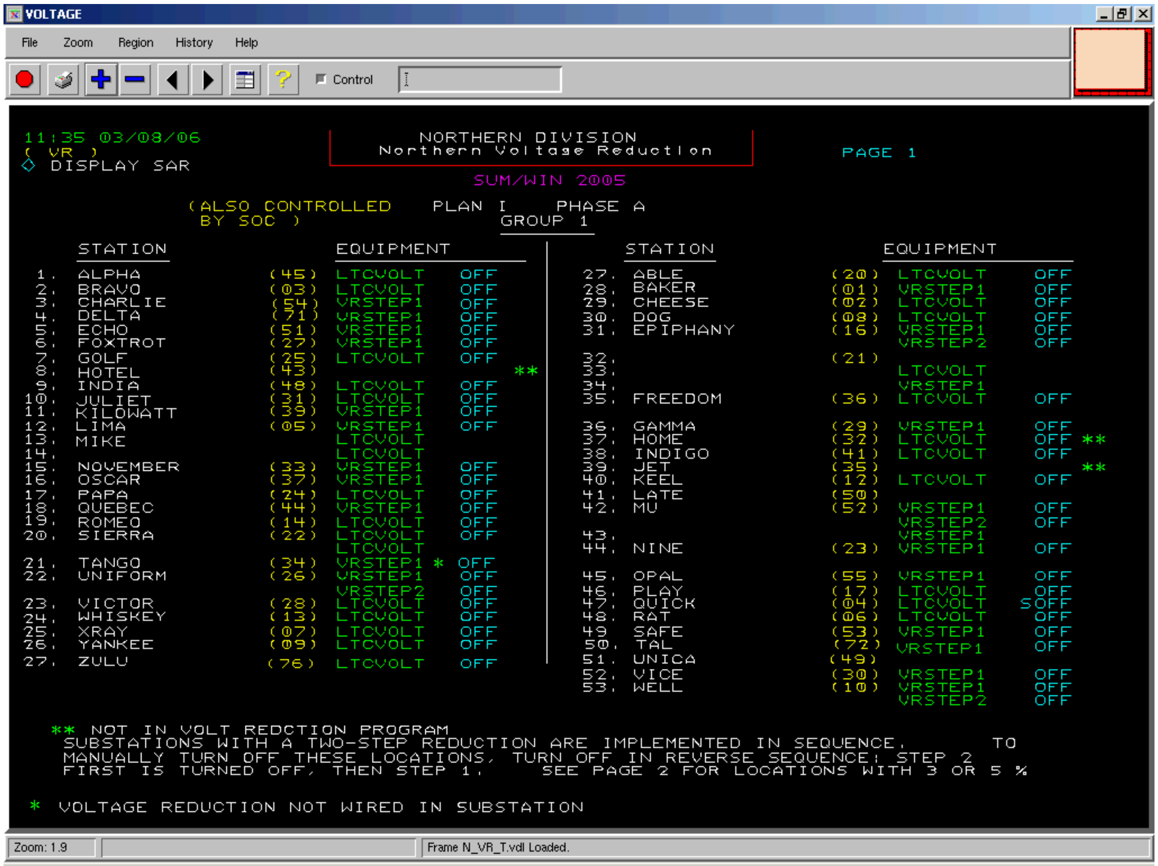


Prior to the development of this application, the previous practice for operator-controllable load-shed was to have the SOC operator (and the DOC operator at the direction of the SOC) use the SCADA systems to send individual circuit breaker trip and close commands to the various substations with circuits eligible for controlled load shedding as identified in the load curtailment plan. This was very time consuming, involved many different substation displays, and made load-shed rotation extremely difficult. Having the load-shed application enhances reliability and situational awareness by allowing quick response to a load-shed directive and overview monitoring of load-shed facility availability and expected response.

The following screen example shows all of the transformers at substations in Dominion's northern division that are controllable for voltage reduction. The actual substation names have been replaced with aliases for security reasons. This screen shows the reduction percentage (3 percent or 5 percent) that is available from each transformer along with the real-time voltage on the associated bus potential transformer secondary (the approximate single-phase voltage that the customers see).



The following screen example shows the status of the voltage reduction equipment at each substation in Dominion's northern division. The actual substation names have been replaced with aliases for security reasons. Equipment statuses preceded by an "S" such as is shown for substation "Quick" on the screen example means that a special order tag has been placed on the equipment. Special order tags usually indicate that some restriction has been placed on the operation of the equipment.



The in-house development of the software to facilitate load shedding and voltage reduction was based upon Dominion's operating needs for implementing its load curtailment plan. System operators provided critical input and feedback during the development. In addition to routine software maintenance of the application performed by the IT staff that supports the DMS, there is an annual, end-to-end load curtailment equipment test to verify correct operation.

Examples of Excellence

EOE-16
Reference — Section 3.6, System Reassessment and Re-posturing
Submitted by — VACAR Subregion of SERC

Description

Tool/Practice Name:	VACAR Guidelines For Addressing Situations Outside of Established Procedures
NERC Registration:	Reliability Coordinator, Transmission Operator, Balancing Authorities

Overview

The VACAR Subregion of SERC has developed documented guidelines to address events on the transmission system that are outside the scope of established operations. These guidelines, which are part of the *VACAR-South Reliability Coordinator Handbook*, are intended for use by the RC working in close coordination with the BAs (TOPs) within the reliability area. These guidelines contain several excellent examples of what to include in a procedure for reassessing and re-posturing the system following an event or events that leave the system in an insecure or unstudied state.

Particularly noteworthy is the section describing a generic approach to problem solving. This approach encompasses assessing the situation, diagnosing the problem, planning corrective actions, implementing the plans, and assessing after the fact the appropriateness of the actions taken. It also stresses communications and coordination among affected parties

The document follows in its entirety.

Procedure Name: Guidelines for Addressing Situations
Revision Date: 1/24/2005
Outside of Established Procedures

VACAR GUIDELINES FOR ADDRESSING SITUATIONS OUTSIDE OF ESTABLISHED PROCEDURES

Purpose

This guideline provides a framework for the reliability coordinator (RC) to use in addressing situations outside of established procedures. The RC shall rely heavily on system expertise that the Control Area (CA) operators have relative to the local area operation of their own systems with regard to problems that may result in the use of this procedure.

Conditions

Various types of conditions may become apparent to the RC that are not addressed in the current Emergency Operating Procedures (EOP). These may include:

• **Over voltage** conditions on a Member system: The RC shall coordinate with the CAs and other RCs to check the status of capacitor banks, voltage control devices, regulated volt-ampere reactive (VAr) reserves. If necessary, the RC will coordinate the removal of lightly loaded Extra High Voltage (EHV) facilities from service or insertion of reactive devices within the affected CA or neighboring CAs.

• **Under voltage** conditions on Member systems: The RC shall coordinate with the member CAs and other RCs to check the status of capacitor banks, voltage control devices, and regulated VAr reserves. If the condition still persists following the validation of the status of all VAr resources, the RC may need to review sales/wheeling schedules for their impact on voltage. It may also be necessary for the CA to consider redispatch of generation.

• **For first contingency transmission overloads** on the bulk transmission network that need to be relieved within a thirty **(30) minute** time frame, the appropriate procedures will be implemented to relieve the overloaded facility. This may include any available local operating procedure or NERC Transmission Loading Relief Procedure (TLRP).

• **For transmission overloads** on the bulk transmission network that need to be relieved immediately, methods listed below will be used to relieve the overloaded facility.

- Removing from service other transmission facilities in the area, which will off-load the overloaded facility.
- Removing from service the overloaded facility itself.
- Return to service any available outaged facilities that will help off-load the overloaded facility.
- Redispatch generation.
- Curtail energy and transmission schedules
- Curtail interruptible customers

• **Stability** of the interconnected network may become a concern of the RC and CA(s). If this is identified as a problem, the RC and the affected CA and other RCs should:

- Verify network topology
  - Determine if local conditions are contributing to the stability problem,
  - If local conditions are not a contributing factor, notify neighboring sub-regional and regional RCs

- Verify the status of Power System Stabilizers (PSSs) in the area.

Problems in other Reliability Coordinator's Security Areas

The problems discussed above (over- and under-voltage, contingency, and stability) may exist in other RC's Reliability Areas and resolution will require coordination between VACAR and these other areas. To the extent that VACAR CAs impact these external problems, the VACAR RC will work, in the manner described above, with those CAs and other RCs to rectify the situation.

Generic Approach to Problem Solving

Should all the above fail to correct problems on the bulk interconnected network under the responsibility of the VACAR RC or problems which the VACAR RC has been requested to help alleviate, the VACAR RC should attempt to solve the problem utilizing a generic approach to problem solving, which will continue to utilize contact with the affected CAs and other RCs. This approach involves five (5) steps. This diagnostic process can aid the RC and system operators in addressing problem situations in a systematic manner. The RC should rely heavily on system expertise that the CAs and other RCs have relative to the local area operation of their own systems with regard to problems that may result in the use of this procedure.

- **Assessment of Situation:** This involves assembling data that is available to the RC, gathering additional data from remote sites and/or systems, and evaluating the evidence. From the large amount of data available, the RC must focus on the data that is critical to the problem. Throughout the process, the RC should remain alert for new data and be prepared to integrate all evidence received. As part of the immediate assessment of the situation, the RC must decide the urgency of the problem and the need for decision or action.

- **Diagnosis of Cause of Problem:** This step involves formulating alternative interpretations of the event, gathering additional information as needed to support or refute the interpretations, and finally determining the most probable cause of the problem. The RC should retain an open mind in reviewing the evidence and examining different possible causes of the problem. Knowledge of previous incidents and of system/equipment history should be used in formulating explanations. A team brainstorming approach including RC and CA resources can be helpful in maintaining the openness at this point in the problem solving process. Once explanations have been formulated, additional information that would help select the explanation can be sought. At this point, the search for information is clearly focused and the questions should be closed rather than open-ended. With further evidence the RC should now be ready to select a working explanation to use in planning a corrective strategy. However, the RC should constantly monitor the system data that may necessitate a change in direction.

- **Planning Corrective Strategy:** When planning a corrective strategy, the RC should identify a workable solution, evaluate the potential consequences of the strategy, communicate the strategy, and plan for contingencies. The strategy should be one that responds to the cause of the problem as identified in the diagnosis. The selected strategy should meet two general guidelines. The strategy should respond to all the identified causes and minimize any potential adverse consequences. In many situations some trade-off of reliability versus economy is involved. In all cases, the RC should plan for contingencies both during and after implementation of the strategy. Once a strategy has been selected, all those involved in its implementation should be informed. All those involved in implementing the strategy and monitoring its effectiveness should be aware of the overall strategy and their role in it. If changes are made, they should also be clearly communicated to all those involved.

- **Implementation of Corrective Strategy:** Implementation of the strategy involves performing the required actions and monitoring the results. All steps of the strategy should be clearly communicated among the affected parties. Confirmation of the steps taken and corresponding results of this strategy should be provided to the RC by the CA(s). The RC should continuously remain alert for new data that may indicate the need for a shift in strategy.

- **After the Fact Analysis:** After the immediate problem has been resolved, the incident should be analyzed to determine whether appropriate actions were taken. After resolution, additional evidence may become available. Real time response to the event should be evaluated and appropriately documented.

EOE-17

Reference — Section 5.1, Display Maintenance Tool
Submitted by — California Mexico Reliability Coordinator (CMRC)

Description

Tool/Practice Name:	Display Maintenance Tool Application
NERC Registration:	Reliability Coordinator

Overview

By using an equivalent display maintenance tool application, CMRC has taken a slightly different approach to ensure that its EMS displays are functioning properly (i.e., showing correct information, linked correctly) to maintain situational awareness for CMRC's operators.

All of CMRC's network application one-lines are derived from auto-generated simplified displays. Most external stations are left in the simplified form. Displays for internal stations are edited to include detailed switching and bus arrangement detail. Elements added to a display are automatically updated in the network model database using the display maintenance tool (through a visual display). This has prevented extended periods of downtimes for certain EMS failures.

Examples of Excellence

EOE-18
Reference — Section 5.2, Change Management Tools and Practices
Submitted by — PJM

Description

Tool/Practice Name: ChPro Change Management Tool

NERC Registration: Reliability Coordinator

Overview

RTBPTF notes that each entity has taken a slightly different approach to ensure that software modifications do not compromise the availability and integrity of critical real-time applications that support operator situational awareness. However, RTBPTF notes that PJM has a feature management system that resides only on their development environment. PJM also has a server identified as the source master server for that environment. Each code change that is made needs to be logged through the feature management system called "ChPro" on the development system. "ChPro" provides audit logging and version control capabilities. Once the code change is logged it can be moved to other environments for testing. Typically these changes are installed and tested on their process control test (PCT) environment, which receives real-time data from their production (PRD) environment to simulate results in the PRD environment. Once tested on the PCT environment, the feature must be logged in a change management system called REMEDY. These features need manager approval as well as operator notification and approval prior to being installed in the PRD environment unless the change is considered an emergency. Emergency changes can be installed immediately upon operator notification and approval to fix a problem. If the change is an emergency change, a REMEDY request must still be submitted for approval by a manager at a later time. Any change installed on the PRD environment is immediately re-tested to insure application integrity and availability. After the change is tested and approved on the PRD environment, it is moved to all other environments to insure synchronization of all systems. The PJM software maintenance tools and processes successfully comply with SAS 70 Type 2 audit standards.

EOE-19
Reference — Section 5.3, Facilities Monitoring
Submitted by — American Electric Power (Central and Southwest)

Description

Tool/Practice Name:	Facilities Monitoring Application
NERC Registration:	Balancing Authority and Transmission Operator

Overview

Using equivalent facilities monitor applications, entities have taken slightly different approaches to ensure that critical equipment and facilities are functioning properly to maintain situational awareness for their operators. Central and Southwest (CSWS) interfaces its facilities monitoring application (called “Big Brother”) with its critical applications monitoring application. This interface provides CSWS with an extremely flexible tool for monitoring and notification (paging) for numerous aspects of it system.

Examples of Excellence

EOE-20
Reference — Section 5.4, Critical Applications Monitoring
Submitted by — Tennessee Valley Authority

Description

Tool/Practice Name:	Critical Applications Monitoring
NERC Registration:	Balancing Authority and Transmission Operator

Overview

Tennessee Valley Authority (TVA) uses a tool that monitors all critical and non-critical processes on their SCADA system. If a process fails, TVA's Network Operations Center can restart the process from a visual display. This has prevented extended downtimes during certain EMS failures.

Examples of Excellence

EOE-21

Reference — Section 5.4, Critical Applications Monitoring
Submitted by — International Transmission Company

Description

Tool/Practice Name: Critical Applications Monitoring

NERC Registration: Transmission Operator

Overview

International Transmission Company uses a tool that monitors the status of its state estimator and ICCP data applications. The tool generates text messages to a cell phone, which are automatically sent to an on-call operations engineer when the state estimator aborts and does not converge. When the data flow rate on the ICCP data links stalls, the tool sends text messages to a cell phone, which automatically goes to on-call IT support personnel and an on-call operations engineer.

Examples of Excellence

EOE-22
Reference — Section 5.4, Critical Applications Monitoring
Submitted by — American Transmission Company

Description

Tool/Practice Name: Critical Applications Monitoring

NERC Registration: Transmission Operator

Overview

American Transmission Company has created overview displays that not only show system performance but also EMS health checks. These overview displays allow the system operator to determine whether the EMS is operational and functioning properly. System operators are required to display these overview visuals and to notify the on-call EMS contact if a problem appears.

Examples of Excellence

EOE-23

Submitted by — American Electric Power (Central and Southwest)

Description

Tool/Practice Name:	Critical Applications Monitoring
NERC Registration:	Transmission Operator

Overview

Central and Southwest (CSWS) interfaces its EMS Facilities Monitoring application (aptly called “Big Brother”) with its critical applications monitor. This interface is an extremely flexible tool for monitoring of and notification (paging) regarding numerous aspects of the CSWS system.

Examples of Excellence

EOE-24
Reference — Section 5.5, Trouble-Reporting Tool
Submitted by — Florida Power and Light

Description

Tool/Practice Name:	Trouble Report System
NERC Registration:	Transmission Operator and Balancing Authority

Overview

Florida Power and Light's (FPL) Trouble Report System (TRS) is a web-based application developed in house to facilitate logging, communication, and tracking of user problems with tools and systems maintained by the computer support group at FPL's System Control Center. Users are primarily operators. In addition to allowing entries of new trouble reports, the application performs administrative functions and can produce different query-based summary reports. The process flow and other functionalities are described below.

New Trouble Report Entry

Whenever a user encounters a problem with a tool or application, s/he can call computer support personnel or initiate a trouble report entry. Even if the user opts to call to report the problem, FPL considers it good practice to initiate a trouble report through TRS to ensure tracking. TRS also has an interface to FPL's e-mail system, so users can track trouble report status and eventual resolution. Trouble reports can be initiated by users or by support personnel that receive a call. When support personnel enter the report, they do so on behalf of the user reporting the problem. Once the user saves the entry, the trouble report status becomes PENDING.

Initial Evaluation

Support group personnel are assigned to periodically scan the TRS for reports with PENDING status and select the appropriate functional area to investigate and resolve each report. When the report is assigned, its status changes to ANALYZE, and an e-mail is automatically issued to the supervisor of the selected functional area notifying him/her of the new trouble report that has been assigned to his/her group.

If information provided by the user is insufficient for personnel to assign a report, the report status can be changed to MORE INFO, which automatically issues an e-mail to the user requesting more information. Once the user provides more information and saves the entry, the status returns to PENDING, and the process begins again.

Functional Area Process

The functional area supervisor, when notified by e-mail of a report, analyzes the problem. (The report can be accessed simply by clicking on the URL link provided in each e-mail issued by TRS.) The supervisor will then do one of the following:

- Assign the trouble report to appropriate personnel — This changes the status of the report to WORK ASSIGNED and generates an e-mail notifying both the staff member assigned to the report and the user that the report has been assigned. The supervisor determines the severity of the problem and assigns a priority to the report: high, medium, or low. The “Trouble Area” and “Application” fields of the report should also be filled in at this time. This information is useful for classifying problems in summary reports.
- Reassign the report to another functional area — The report status remains ANALYZE, and an e-mail is sent to the supervisor of the new functional area.
- Ask for more information regarding the problem — The supervisor can change the status of the report to MORE INFO, which generates an e-mail to the user requesting more information. Once the user provides more information and saves the entry, the status returns to ANALYZE, and an e-mail is issued to the functional area supervisor.

Trouble Resolution

The analyst assigned the trouble report reviews the severity of the problem and determines, based on workload, when to begin work on the problem. During the resolution stage, any of the following may occur:

- Problem is corrected — Once the analyst resolves the problem, s/he changes the report status to FIXED and describes the resolution. If the resolution requires code changes, the “Code Change Req” flag is selected, and modules that have been modified are specified in the resolution description. TRS automatically issues an e-mail to the user who reported the problem and to the functional area supervisor indicating that the problem has been fixed.
- No action could be taken to resolve the problem — This may be a result of an inability to duplicate the problem or determination that resolution of the problem would constitute a system enhancement, which requires that it go through a change management process. In this case, the analyst updates the status of the report to NO ACTION. TRS automatically issues an e-mail notifying the user who reported the problem and the functional area supervisor of the status change.
- Need more information from the user — The analyst can change the status of the report to MORE INFO. This generates an e-mail to the user requesting more information. Once the user provides more information and saves the entry, the status returns to WORK ASSIGNED, and an e-mail is sent to the analyst.

User Feedback

The user who initiated the report should verify that the problem has been corrected or agree that the problem is an enhancement that requires initiation of a change request. In both cases the user should update the status of the trouble report to CLOSED. If s/he disagrees with the resolution, a description of the disagreement is entered, and the status should be changed to NOT FIXED, which generates an e-mail back to the analyst.

Administrative Functions

TRS will e-mail weekly reports to each functional area supervisor listing all outstanding trouble reports assigned to their groups. These reports are copied to management. Outstanding trouble reports are those with a current status of ANALYZE, MORE INFO, WORK ASSIGNED, or NOT FIXED. TRS provides the following statistics on a per-trouble-report basis:

- Time elapsed from a report's first entry to the system to its assignment to a functional area
- Time elapsed from assignment to a functional area to assignment to an analyst
- Time elapsed from assignment to an analyst to resolution
- Total time spent on a trouble report (from initial entry to completion)
- Total number of times that a trouble report was returned by user as not fixed

2011 Southwest Outage Report

Arizona-Southern California Outages on September 8, 2011

Causes and Recommendations

Prepared by the Staffs of the

Federal Energy Regulatory Commission
and the
North American Electric Reliability Corporation

April 2012

TABLE OF CONTENTS

I. EXECUTIVE SUMMARY

A. Synopsis of the Disturbance and System Recovery

On the afternoon of September 8, 2011, an 11-minute system disturbance occurred in the Pacific Southwest, leading to cascading outages and leaving approximately 2.7 million customers without power.[1] The outages affected parts of Arizona, Southern California, and Baja California, Mexico. All of the San Diego area lost power, with nearly one-and-a-half million customers losing power, some for up to 12 hours. The disturbance occurred near rush hour, on a business day, snarling traffic for hours. Schools and businesses closed, some flights and public transportation were disrupted, water and sewage pumping stations lost power, and beaches were closed due to sewage spills. Millions went without air conditioning on a hot day.

The loss of a single 500 kilovolt (kV)[2] transmission line initiated the event, but was not the sole cause of the widespread outages. The system is designed, and should be operated, to withstand the loss of a single line, even one as large as 500 kV. The affected line—Arizona Public Service's (APS) Hassayampa-N. Gila 500 kV line (H-NG)—is a segment of the Southwest Power Link (SWPL), a major transmission corridor that transports power in an east-west direction, from generators in Arizona, through the service territory of Imperial Irrigation District (IID), into the San Diego area. It had tripped on multiple occasions, as recently as July 7, 2011, without causing cascading outages.

With the SWPL's major east-west corridor broken by the loss of H-NG, power flows instantaneously redistributed throughout the system, increasing flows through lower voltage systems to the north of the SWPL, as power continued to flow into San Diego on a hot day during hours of peak demand. Combined with lower than peak

[1] "Customers" are not the same as "people" in utility parlance. The term customer generally refers to a single meter, whether at a residence, an apartment building, or a factory. Thus, a single customer could represent one or more persons, and a single person could be two customers, for example, if the same utility served both an individual's residence and his small business. Estimates of "people" affected by blackouts generally are prepared by increasing the customer numbers by a multiplier, often two or three.

[2] A list of acronyms used in this report is included in Appendix A.

generation levels in San Diego and Mexico,[3] this instantaneous redistribution of power flows created sizeable voltage deviations and equipment overloads to the north of the SWPL. Significant overloading occurred on three of IID's 230/92 kV transformers located at the Coachella Valley (CV) and Ramon substations, as well as on Western Electricity Coordinating Council (WECC) Path 44,[4] located south of the San Onofre Nuclear Generating Station (SONGS) in Southern California.

The flow redistributions, voltage deviations, and resulting overloads had a ripple effect, as transformers, transmission lines, and generating units tripped offline, initiating automatic load shedding throughout the region in a relatively short time span. Just seconds before the blackout, Path 44 carried all flows into the San Diego area as well as parts of Arizona and Mexico. Eventually, the excessive loading on Path 44 initiated an intertie separation scheme at SONGS, designed to separate SDG&E from SCE. The SONGS separation scheme separated SDG&E from Path 44, led to the loss of the SONGS nuclear units, and eventually resulted in the complete blackout of San Diego and Comisión Federal de Electricidad's (CFE) Baja California Control Area. During the 11 minutes of the event, the WECC Reliability Coordinator (WECC RC) issued no directives and only limited mitigating actions were taken by the Transmission Operators (TOPs) of the affected areas.

As a result of the cascading outages stemming from this event, customers in the SDG&E, IID, APS, Western Area Power Administration-Lower Colorado (WALC), and CFE territories lost power, some for multiple hours extending into the next day. Specifically,

- SDG&E lost 4,293 Megawatts (MW) of firm load, affecting approximately 1.4 million customers.
- CFE lost 2,150 MW of net firm load, affecting approximately 1.1 million customers.[5]
- IID lost 929 MW of firm load, affecting approximately 146,000 customers.

---

[3] Total summer peak generation for San Diego Gas and Electric's (SDG&E) territory and Comisión Federal de Electricidad's (CFE) Baja California Control Area is 5,774 MW. On September 8, 2011, the total generation for SDG&E and CFE's Baja California Control Area was 4,168, a difference of 1,606 MW.

[4] Path 44 is one of 81 Rated Paths in the WECC region. A Rated Path is composed of "an individual transmission line or a combination of parallel transmission lines." WECC 2011 Path Rating Catalog, January 2011, at item 1-i. Path 44, also referred to as "South of SONGS," is an aggregation of five 230 kV lines that delivers power in a north-south direction from the Southern California Edison (SCE) footprint in the Los Angeles area into the SDG&E footprint.

[5] CFE is Mexico's state-owned utility. Only its Baja California Control Area was affected on September 8, 2011. The inquiry is particularly grateful to CFE for its willingness to share data and information to assist the inquiry in developing the most accurate conclusions and recommendations.

- APS lost 389 MW of firm load, affecting approximately 70,000 customers.
- WALC lost 74 MW of firm load, 64 MW of which affected APS's customers. The remaining 10 MW affected 5 WALC customers.

After the blackout, the affected entities promptly instituted their respective restoration processes.[6] All of the affected entities had access to power from their own or neighboring systems and, therefore, did not need to use "black start" plans.[7] Although there were some delays in the restoration process due to communication and coordination issues between entities, the process was generally effective. SDG&E took 12 hours to restore 100% of its load, and CFE took 10 hours to restore 100% of its load. IID, APS, and WALC restored power to 100% of their customers in approximately 6 hours. The affected entities also worked to restore generators and transmission lines that tripped during the event. IID and APS restored generation—333 MW for IID and 76 MW for APS—in 5 hours. Meanwhile, CFE restored 1,915 MW of tripped generation in 56 hours; SDG&E restored 2,229 MW of tripped generation in 39 hours; and SCE restored 2,428 MW of tripped generation in 87 hours. IID restored its 230 kV transmission system in 12 hours and its 161 kV system in 9 hours; APS restored H-NG in 2 hours; SDG&E restored its 230 kV system in 12 hours; WALC restored its 161 kV system in 1.5 hours; and CFE restored its 230 kV system in 13 hours and its 115 kV system in 10 hours.

B. Map of Affected Area and Key Facilities Involved in the Event

The following map, showing the areas affected by the September 8th event and the key facilities involved during the event, can be used as a reference throughout the report:

[6] The term "affected entities" in this report refers to TOPs and Balancing Authorities (BAs) that were affected by the event. The affected entities include SDG&E, IID, APS, WALC, SCE, CFE, and the California Independent System Operator (CAISO).

[7] Black start plans work to energize systems using internal generation to get from shutdown to operating condition without assistance from the Bulk Electric System (BES).

C. Key Findings, Causes, and Recommendations[8]

The September 8, 2011, event showed that the system was not being operated in a secure N-1 state.[9] This failure stemmed primarily from weaknesses in two broad areas—operations planning and real-time situational awareness—which, if done properly, would have allowed system operators to proactively operate the system in a secure N-1 state during normal system conditions and to restore the system to a secure N-1 state as soon as possible, but no longer than 30 minutes. Without adequate planning and situational awareness, entities responsible for operating and overseeing the transmission system could not ensure reliable operations within System Operating Limits (SOLs) or prevent cascading outages in the event of a single contingency.[10] As demonstrated in Appendix C, inadequate situational awareness and planning were also identified as causes of the 2003 blackout that affected an estimated 50 million people in the United States and Canada.

The inquiry also identified other underlying factors that contributed to the event, including: (1) not identifying and studying the impact on Bulk-Power System (BPS)[11]

---

[8] While this section highlights the most significant causes, findings, and recommendations, the report details the complete list of findings, causes, and recommendations in section IV. In addition, for ease of reference all of the findings and recommendations are summarized in table format in Appendix B.

[9] The North American Electric Reliability Corporation's (NERC) mandatory Reliability Standards applicable to the BES require that the BES be operated so that it generally remains in a reliable condition, without instability, uncontrolled separation or cascading, even with the occurrence of any single contingency, such as the loss of a generator, transformer, or transmission line. This is commonly known as the "N-1 criterion." N-1 contingency planning allows entities to identify potential N-1 contingencies before they occur and to adopt mitigating measures, as necessary, to prevent instability, uncontrolled separation, or cascading. As the Federal Energy Regulatory Commission (Commission) stated in Order No. 693 with regard to contingency planning, "a single contingency consists of a failure of a single element that faithfully duplicates what will happen in the actual system. Such an approach is necessary to ensure that planning will produce results that will enhance the reliability of that system. Thus, if the system is designed such that failure of a single element removes from service multiple elements in order to isolate the faulted element, then that is what should be simulated to assess system performance." *Mandatory Reliability Standards for the Bulk Power System*, Order No. 693, FERC Stats. & Regs. ¶ 31,242, at P 1716 (2007), *order on reh'g, Mandatory Reliability Standards for the Bulk-Power System*, 120 FERC ¶ 61,053 (Order No. 693-A) (2007).

[10] A contingency is the unexpected failure of an electrical system component.

[11] The BPS is defined by Section 215(a) (1) of the Federal Power Act as "facilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof), and electric energy from generating facilities needed to maintain transmission system reliability." The meaning of BPS and BES differ somewhat and, thus, this report uses each term in its proper context. With respect to reliability, the Commission has jurisdiction over all users, owners, and operators of the BPS. In Order No. 693 at P 75, the Commission adopted, at least for an initial period, the BES definition as the threshold for application of the NERC Reliability Standards. Thus, this report uses BES when referring to entities' specific facilities or elements that are subject to the Reliability Standards, but BPS when discussing the overall reliability impact. On January 25, 2012, NERC filed a petition with the Commission for approval of a revised definition of the BES. The proposed definition of BES would cover all elements operated at 100 kV or higher, with a list of specific inclusions and exclusions.

reliability of sub-100 kV facilities in planning and operations;[12] (2) the failure to recognize Interconnection Reliability Operating Limits (IROLs) in the Western Interconnection;[13] (3) not studying and coordinating the effect of protection systems, including Remedial Action Schemes (RASs), during plausible contingency scenarios;[14] and (4) not providing effective tools and operating instructions for use when reclosing lines with large phase angle differences across the reclosing breakers.[15]

With regard to operations planning, some of the affected entities' seasonal, next-day, and real-time studies do not adequately consider: (1) operations of facilities in external networks, including the status of transmission facilities, expected generation output, and load forecasts; (2) external contingencies that could impact their systems or internal contingencies that could impact their neighbors' systems; and (3) the impact on BPS reliability of internal and external sub-100 kV facilities. As a result, these entities' operations studies did not accurately predict the impact of the loss of APS's H-NG or the loss of IID's three 230/92 kV transformers. If the affected entities had more accurately predicted the impact of these losses prior to the event, these entities could have taken appropriate pre-contingency measures, such as dispatching additional generation to mitigate overloads and prevent cascading outages.

To improve operations planning in the WECC region, this report makes several recommendations designed to ensure that TOPs and BAs,[16] as appropriate: (1) obtain information on the operations of neighboring BAs and TOPs, including transmission outages, generation outages and schedules, load forecasts, and scheduled interchanges; (2) identify and plan for external contingencies that could impact their systems and

Transformers with the primary terminal and at least one secondary terminal operated at 100 kV or higher are on the list of specific inclusions. *See North American Electric Reliability Corp.,* Docket No. RM12-6-000. This report takes no position on the petition.

[12] This report does not attempt to define the limits of which sub-100 kV facilities impact BPS reliability. Certainly, many facilities below 100 kV do not impact BPS reliability. The sub-100 kV facilities in this event affected the BPS because they were in parallel to significant transmission corridors.

[13] This report recommends that WECC RC should work with TOPs to consider whether any SOLs in the Western Interconnection constitute IROLs. As part of this effort, WECC RC should: (1) work with affected TOPs to consider whether Path 44 and H-NG should be recognized as IROLs; and (2) validate existing SOLs and ensure that they take into account all transmission and generation facilities and protection systems that impact BPS reliability.

[14] This failure caused the derived SOLs on H-NG and Path 44 to be invalid on the day of the event.

[15] As discussed in more detail in connection with Finding and Recommendation 27 below, when a line trips, the phase angle at one end of the line may be much larger than the phase angle at the other end. If the difference between the two angles is too great, reclosing the line could cause damage to generators or even system instability.

[16] See "Reliability Responsibilities" section at page 16 below.

internal contingencies that could impact their neighbors' systems; and (3) consider facilities operated at less than 100 kV that could impact BPS reliability. This effort should include a coordinated review of planning studies to ensure that operation of the affected Rated Paths will not result in the loss of non-consequential load, system instability, or cascading outages, with voltage and thermal limits within applicable ratings for N-1 contingencies originating from within or outside an entity's footprint.

The September 8th event also exposed entities' lack of adequate real-time situational awareness of conditions and contingencies throughout the Western Interconnection. For example, many entities' real-time tools, such as State Estimator and Real-Time Contingency Analysis (RTCA), are restricted by models that do not accurately or fully reflect facilities and operations of external systems to ensure operation of the BPS in a secure N-1 state. Also, some entities' real-time tools are not adequate or operational to alert operators to significant conditions or potential contingencies on their systems or neighboring systems. The lack of adequate situational awareness limits entities' ability to identify and plan for the next most critical contingency to prevent instability, uncontrolled separation, or cascading outages. If some of the affected entities had been aware of real-time external conditions and run (or reviewed) studies on the conditions prior to the onset of the event, they would have been better prepared for the impacts when the event started and may have avoided the cascading that occurred.

To improve situational awareness in the WECC region, this report makes several recommendations: (1) expand entities' external visibility in their models through, for example, more complete data sharing; (2) improve the use of real-time tools to ensure the constant monitoring of potential internal or external contingencies that could affect reliable operations; and (3) improve communications among entities to help maintain situational awareness. In addition, TOPs should review their real-time monitoring tools, such as State Estimator and RTCA, to ensure that such tools represent critical facilities needed for the reliable operation of the BPS. These improvements will enable system operators to utilize real-time operating tools to proactively operate the system in a secure N-1 state.

In addition to the planning and situational awareness issues, several other factors contributed to the September 8th event. For example, WECC RC and affected entities do not consistently recognize the adverse impact that sub-100 kV facilities can have on BPS reliability. The prevailing SOLs should have included the effects of facilities that had not been identified and classified as part of the BES, as well as the effects of critical facilities such as Special Protection Systems (SPSs) and the SONGS separation scheme. Relevant to the event, these entities did not consider IID's 92 kV network and facilities, including the CV and Ramon 230/92 kV transformers, as part of the BES, despite some previous studies indicating their impact on the BPS due to the fact they were electrically in parallel with higher-voltage facilities.[17] If these facilities had been designated as part of the BES, or otherwise incorporated into planning and operations studies and actively monitored and alarmed in RTCA systems, the cascading outages may have been avoided. Accordingly, the inquiry makes a recommendation to ensure that facilities that can impact BPS reliability, regardless of voltage level, are considered for classification as part of the BES and/or studied as part of entities' planning in various time horizons.

The inquiry also found some significant issues with protection system settings and coordination. For example, IID used conservative overload relay trip settings on its CV transformers. The relays were set to trip at 127% of the transformers' normal rating, which is just above the transformers' emergency rating (110% of normal rating). Such a narrow margin between the emergency rating and overload trip setting resulted in the facilities being automatically removed from service without providing operators enough time to mitigate the overloads. As a result of these settings, both CV transformers tripped within 40 seconds of H-NG tripping, initiating cascading outages. To avoid a similar problem in the future, the inquiry recommends that IID and other Transmission Owners (TOs) review their transformers' overload protection relay settings. A good guideline for protective relay settings is Reliability Standard PRC-023-1 R1.11, which states that relays be "set to allow the transformer to be operated at an overload level of at least 150% of the maximum applicable nameplate rating, or 115% of the highest operator established emergency transformer rating, whichever is greater." TOPs should also plan to take proper pre-contingency mitigation measures with due consideration for the applicable emergency ratings and overload protection settings (MW and time delay) before a facility loads to its relay trip point and is automatically removed from service.

The SONGS separation scheme's operation provides another example of the lack of studies on, and coordination of, protection systems. This scheme, classified by SCE as a "Safety Net,"[18] had a significant impact on BPS reliability, separating SDG&E from SCE, resulting in the loss of both SONGS nuclear generators, and blacking out SDG&E

[17] *See, e.g.*, CFE's Path 45 Increase Rating Phase 2 Study Report, January 12, 2011, at 19.

[18] A Safety Net protection system protects the power system from unexpected, low-probability events that are outside the normal planning criteria, but which may lead to a complete system collapse. Safety Nets operate to minimize the severity of the event and attempt to prevent a system collapse or cascading outages. A Safety Net is typically intended to handle severe disturbances resulting from extreme, though perhaps not well-defined, events. A Safety Net is subject to review by the WECC Remedial Action Scheme Reliability Subcommittee if unintended operation would result in cascading or other performance standard violations. WECC Guideline: Remedial Action Scheme Classification, February 9, 2009.

and CFE. Nevertheless, none of the affected entities, including SCE, as the owner and operator of the scheme, studied its impact on BPS reliability. The September 8th event shows that all protection systems and separation schemes, including Safety Nets, RASs, and SPSs, should be studied and coordinated periodically to understand their impact on BPS reliability to ensure their operation, inadvertent operation, or misoperation does not have unintended or undesirable effects.

II. INTRODUCTION

A. Inquiry Process

On September 9, 2011, the Commission and NERC jointly announced an inquiry to determine the causes of the outages and make recommendations for preventing such events in the future. The purpose of the inquiry was not to determine whether there may have been violations of applicable regulations, requirements, or standards subject to the Commission's jurisdiction. Thus, while this report describes conduct which may warrant future investigations under Part 1b of the Commission's regulations,[19] or actions by NERC under its Compliance Monitoring and Enforcement Program,[20] it draws no conclusions about whether violations occurred.

The inquiry was composed of smaller teams with particular subject-matter expertise, primarily from Commission and NERC professional staff, each of which conducted rigorous analyses of a key issue or issues involved in the event. Those teams and their primary responsibilities were as follows:

- **Sequence of Events** – developed a precise and accurate sequence of events (SOE) to provide a foundation for root cause analysis, computer model simulations, and other analytical aspects of the inquiry.
- **System Modeling and Simulation** – developed an accurate system modeling case, benchmarked the case to actual conditions at critical times, replicated system conditions leading up to and during the outage, and simulated alternate "what if" scenarios.
- **Root Cause and Human Performance Analysis** – performed in a systematic evaluation of the root causes and contributing factors and identified areas requiring further inquiry.
- **Operations Tools, Supervisory Control and Data Acquisition (SCADA)/Energy Management System (EMS), Communications, and Operations Planning** – considered all aspects of the blackout related to operator and reliability coordinator knowledge of system conditions, actions or inactions, and communications, particularly the observability of the electric system and effectiveness of operational reliability assessment tools.
- **Frequency/Area Control Error (ACE) Analysis** – reviewed potential frequency anomalies related to the blackout, and analyzed underfrequency generator, load, and tie line tripping.

[19] 18 C.F.R. Part 1b (2011).

[20] NERC Compliance Monitoring and Enforcement Program, Appendix 4C to the NERC Rules of Procedure, January 31, 2012.

- **System Planning, Design, and Studies** – analyzed factors used in setting SOLs and actual limits in effect on the day of the blackout, determined whether those limits were exceeded, and analyzed the extent to which actual system conditions varied from the assumptions used in setting the SOLs.
- **Transmission and Generation Performance, Protection, Control, Maintenance, and Damage** – analyzed the causes of automatic facility operations and generator trips, analyzed transmission and generation facility maintenance practices, and identified equipment damage.
- **Restoration Review** – reviewed the appropriateness and effectiveness of the restoration plans implemented, as well as the effectiveness of the coordination of these plans among the affected entities and WECC RC.

Each team not only examined its own subject area to determine what may have contributed to the event, but also considered lessons learned and potential recommendations for preventing such events in the future.

The inquiry devoted substantial time and resources to determine and study the causes of the event and develop meaningful recommendations with the goal of preventing similar events in the future. The team's analyses were extensive, involving the review of high-quality data from various reliability entities in the WECC region and simulations of the event using sophisticated computer models. Described below in summary form are the primary steps the inquiry took to complete its analysis.

Data Gathering

The inquiry received and reviewed more than 20 gigabytes of data from approximately 500 data requests sent to entities in and around the affected areas. On September 19, 2011, the inquiry also began site visits with various entities involved in the outages, including entities with responsibility for balancing load and generation, transmission operation, and reliability coordination. During the site visits, the inquiry toured control centers, conducted dozens of interviews and depositions, and viewed equipment involved in the event. These visits and depositions allowed the inquiry to learn about control room operations and practices, system status and conditions on the day of the event, operating procedures, planning, operations, and real-time tools, and restoration planning and procedures. The inquiry also conducted dozens of follow-up meetings and issued follow-up data requests.

Of particular use to the inquiry were phasor measurement unit (PMU) records. PMUs are complex, multi-functional, high resolution recording devices installed widely throughout the Western Interconnection pursuant to a voluntary WECC-wide initiative. PMUs provide continuous, high-speed (30 scans per second) records of system conditions, including frequency, voltage, and phase angle relations. The continuous nature of the data available through the PMUs, as well as their wide distribution throughout the power system, proved especially valuable to the inquiry in forming an accurate picture of the SOE and state of the system at particular points in time throughout the disturbance.

SOE Methodology

More than 100 notable events occurred in less than 11 minutes on September 8, 2011. The inquiry's SOE team established a precise and accurate sequence of outage-related events to form a critical building block for the other parts of the inquiry. It provided, for example, a foundation for the root cause analysis, computer-based simulations, and other event analyses. Although entities time-stamp much of the data related to specific events, their time-stamping methodologies vary, and not all of the time-stamps were synchronized to the National Institute of Standards and Technology (NIST) standard clock in Boulder, Colorado. Validating the precise timing of specific events became a time-consuming, important, and sometimes difficult task. The availability of global positioning system (GPS)-time synchronized PMU data on frequency, voltage, and related power angles made this task much easier than in previous blackout inquiries and investigations.

To develop the SOE, the SOE team started by resolving discrepancies between the multiple sources of data, sign convention inconsistencies, and incorrect data. The SOE team then developed an events database starting with all known events and times. Initial sources for the development of the database included preliminary reports filed by the affected entities as well as initial responses to data requests. The team then examined each record in the database to verify event times using available SCADA and PMU data. As the frequency, line flow, or voltage data suggested that additional events might have occurred on the system, the team added other possible events and verified them through additional data requests.

The SOE team developed multiple iterations of an SOE narrative document based on the database and the available SCADA and PMU data. Some iterations of the SOE narrative required that more data be requested of affected entities, and ultimately multiple data requests were sent to each entity. After the team completed the SOE narrative, the inquiry's Modeling and Simulation team verified the SOE using power flow, voltage stability, and dynamic stability analyses.

Power Flow and Dynamics Analysis

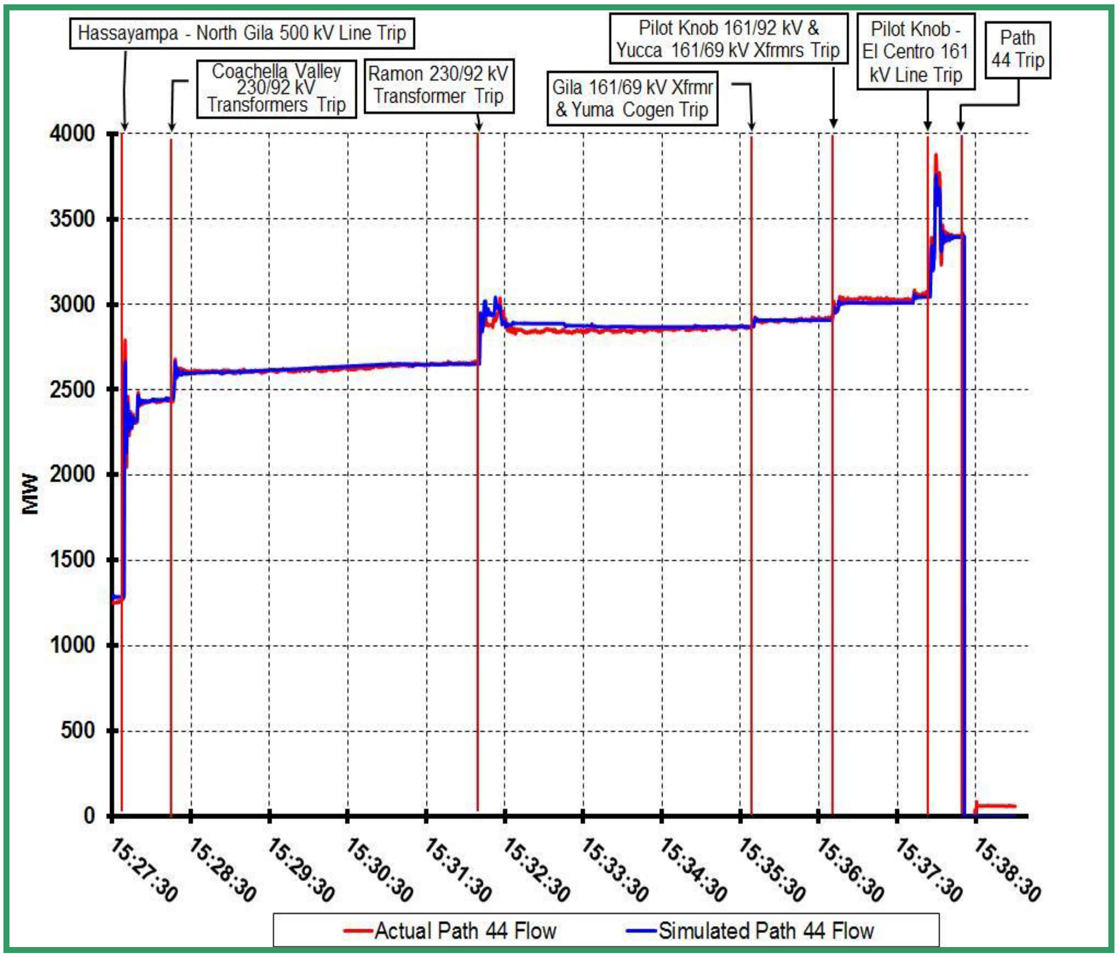
The inquiry's Modeling and Simulation team, after validating the SOE, considered several "what if" scenarios. The Modeling and Simulation team's work is described in more detail in Appendix D. Power flow analyses study power systems under quasi-steady-state conditions by matching load and generation to obtain voltage magnitude and angle at each bus and the real and reactive power flowing through each transmission facility. Dynamic stability analyses study the impact of disturbances on frequency, voltage, and rotor angle stability, and determine whether transients in the power system are stable, thus allowing the power system to return to a quasi-steady-state operating condition following a disturbance.[21]

As the first step in performing power flow and dynamic stability analyses, the Modeling and Simulation team developed and benchmarked a modeling case of system conditions prior to the event. The team started with the WECC heavy summer base case and made adjustments based on State Estimator snapshots, EMS data, actual generation and schedules, PMU data, and a base case prepared by a separate team (led by CAISO) that studied the event. The team further adjusted and benchmarked the base case using SCADA and PMU data to match the system conditions for the entire event. The team devoted considerable time and effort to resolving discrepancies between the various sources of data to best calibrate the modeling case to actual measured data. As illustrated by ***Figure* 1**, on the next page, and described in more detail in Appendix D, the Modeling and Simulation team achieved a significant degree of accuracy. This figure compares Path 44 flows simulated by the Modeling and Simulation team to actual Path 44 PMU data.

After developing and benchmarking a valid case, the Modeling and Simulation team simulated the entire SOE using both power flow and dynamic simulations. This replication of the SOE established the validity of the model and enabled meaningful simulation of several alternative scenarios, developed to answer "what if" questions regarding the event. For example, the inquiry considered what would have happened if some of the affected entities had dispatched generation at certain locations during the event, if overload relays had been set at different levels, or if RASs, Safety Nets, or other SPSs had been designed or operated differently.

[21] Transient stability refers to the ability of synchronous generators to move to a new quasi-steady-state operating point while remaining synchronized after the system experiences a disturbance.

Figure 1: Comparison of Actual and Simulated Path 44 Flows



Outreach Sessions

After developing a list of preliminary findings and recommendations, the inquiry conducted outreach meetings with various industry associations and groups, including CAISO, WECC, the American Public Power Association (APPA), the North American Transmission Forum (NATF), the Edison Electric Institute (EEI), the National Rural Electric Cooperative Association (NRECA), and representatives from Regional Entities (REs), Regional Transmission Organizations, and Independent System Operators. Team members shared the inquiry's preliminary findings and recommendations on a non-public basis with members of these organizations to obtain feedback and, with respect to the recommendations, input as to their practicality and feasibility. The inquiry considered the feedback and input provided by these organizations and incorporated much of it into the findings and recommendations included in this report.

B. System Overview

This subsection provides an overview of: (1) the Western Interconnection and its position in the North American electric grid; (2) the reliability entities responsible for operating the grid; (3) a description of the affected entities; and (4) a discussion of the interconnected nature of these entities.

The Western Interconnection and Its Position in the North American Electric Grid

NERC shares its mission of ensuring the reliability of the BPS in North America with eight REs through a series of delegation of authority agreements. WECC is the designated RE responsible for coordinating and promoting BPS reliability in the Western Interconnection. In its capacity as the RE, WECC monitors and enforces compliance with Reliability Standards by the users, owners, and operators of the BPS. WECC also functions as an Interconnection-wide planning facilitator, aiding in transmission and resource integration planning at the request of its members, as well as a provider of data, analysis, and studies related to transmission planning and reliability issues.

The WECC region extends from Canada to Mexico. It includes the provinces of Alberta and British Columbia, the northern portion of Baja California, Mexico, the states of Washington, Oregon, California, Idaho, Nevada, Utah, Arizona, Colorado, Wyoming, and portions of Montana, South Dakota, New Mexico, and Texas. See ***Figure*** **2**, on the next page. The WECC region is nearly 1.8 million square miles in size, has over 126,000 miles of transmission, and serves a population of 78 million. WECC contains 37 BAs and 53 TOPs. Due to the diverse characteristics of this extensive region, WECC encounters unique challenges in day-to-day coordination of its interconnected system. WECC is tied to the Eastern Interconnection through a number of high-voltage direct current transmission ties.

WECC also operates two RC offices that provide situational awareness and real-time monitoring of the entire Western Interconnection. WECC RC was an affected entity, and will be discussed with other affected entities below.

Figure 2: Map of WECC Region

Reliability Responsibilities

NERC categorizes the entities responsible for planning and operating the BPS in a reliable manner into multiple functional entity types. The NERC functional entity types most relevant to this event are BAs, TOs, TOPs, Generator Operators (GOPs), Planning Coordinators (PCs), Transmission Planners (TPs), and RCs. These functions are described in more detail in NERC's Reliability Functional Model.[22] Some of the affected entities conduct multiple reliability functions.

- ### Balancing Authority

The BA integrates resource plans ahead of time, maintains in real time the balance of electricity resources (generation and interchange) and electricity demand or load within its footprint, and supports the Interconnection frequency in real time. There

[22] NERC Reliability Functional Model, Version 5, http://www.nerc.com/files/Functional_Model_V5_Final_2009Dec1.pdf.

are 37 BAs in the WECC footprint. The following five BAs were affected by the event: APS, IID, WALC, CAISO, and CFE.

- **Transmission Owner, Transmission Operator and Generator Operator**

The TO owns and maintains transmission facilities. The TOP is responsible for the real-time operation of the transmission assets under its purview. The TOP has the authority to take corrective actions to ensure that its area operates reliably. The TOP performs reliability analyses, including seasonal and next-day planning and RTCA, and coordinates its analyses and operations with neighboring BAs and TOPs to achieve reliable operations. It also develops contingency plans, operates within established SOLs, and monitors operations of the transmission facilities within its area. There are 53 TOPs in the WECC region. The following seven TOPs were affected by the event: APS, IID, WALC, CAISO, CFE, SDG&E, and SCE. The GOP operates generating unit(s) and performs the functions of supplying energy and other services required to support reliable system operations, such as providing regulation and reserve capacity.

- **Planning Coordinator**

The PC is responsible for coordinating and integrating transmission facility and service plans, resource plans, and protection systems.[23]

- **Transmission Planner**

The TP is responsible for developing a long-term (generally one year and beyond) plan for the reliability of the interconnected bulk transmission systems within its portion of the Planning Coordinator Area.

- **Reliability Coordinator**

The RC and TOP have similar roles, but different scopes. The TOP directly maintains reliability for its own defined area. The RC is the "highest level of authority" according to NERC, and maintains reliability for the Interconnection as a whole. Thus, the RC is expected to have a "wide-area" view of the entire Interconnection, beyond what any single TOP could observe, to ensure operation within IROLs.

The RC oversees both transmission and balancing operations, and it has the authority to direct other functional entities to take certain actions to ensure reliable

[23] PCs are the same as Planning Authorities (PAs) with respect to NERC registration and the Reliability Standards.

operation. The RC, for example, may direct a TOP to take whatever action is necessary to ensure that IROLs are not exceeded.[24] The RC performs reliability analyses including next-day planning and RTCA for the Interconnection, but these studies are not intended to substitute for TOPs' studies of their own areas. Other responsibilities of the RC include responding to requests from TOPs to assist in mitigating equipment overloads. The RC also coordinates with TOPs on system restoration plans, contingency plans, and reliability-related services.

Descriptions of Affected Entities

The following entities were affected by the September 8th event:

- ### WECC RC

In its capacity as the RC, WECC is the highest level of authority responsible for the reliable operation of the BPS in the Western Interconnection. WECC RC oversees the operation of the Western Interconnection in real time, receiving data from entities throughout the entire Interconnection, and providing high-level situational awareness for the entire system. WECC RC can direct the entities it oversees to take certain actions in order to preserve system reliability. Although WECC is both an RE and an RC, these two functions are organizationally separated.

- ### Imperial Irrigation District

IID, which encompasses the Imperial Valley, the eastern part of Coachella Valley in Riverside County, and a small portion of San Diego County, in California, owns and operates generation, transmission, and distribution facilities in its service area to provide comprehensive electric service to its customers. Thus, IID is a vertically integrated utility. IID's generation consists of hydroelectric units on the All-American Canal as well as oil-, nuclear-, coal-, and gas-fired generation facilities, with a total net capability of 514 MW. IID purchases power from other electric utilities to meet its peak demands in summer, which can exceed 990 MW. IID's transmission system consists of approximately 1,400 miles of 500, 230, 161, and 92 kV lines, as well as 26 transmission substations. Among other NERC registrations, IID is a TOP, BA, and TP responsible for

[24] For example, IRO-005-1 R.5 requires that "[e]ach [RC] shall identify the cause of any potential or actual SOL or IROL violations. The [RC] shall initiate the control action or emergency procedure to relieve the potential or actual IROL violation without delay, and no longer than 30 minutes. The [RC] shall be able to utilize all resources, including load shedding, to address an IROL violation."

resource and transmission planning, load balancing, and frequency support for its footprint.

- **Arizona Public Service**

APS is a vertically integrated utility that serves a 50,000 square mile territory spanning 11 of Arizona's 15 counties. Among other NERC registrations, APS is the TOP and BA for its territory. APS engages in both marketing and grid operation functions, which are separated. APS owns and operates transmission facilities at the 500 (including H-NG), 345, 230, 115, and 69 kV levels, and owns approximately 6,300 MW of installed generation capacity. APS's 2011 peak load was 7,087 MW.

- **Western Area Power Administration – Lower Colorado**

WALC is one of the four entities constituting the Western Area Power Administration, a federal power marketer within the United States Department of Energy. WALC operates in Arizona, Southern California, Colorado, Utah, New Mexico, and Nevada, and is registered with NERC as a BA, TOP, and PC for its footprint. As a net exporter of energy, WALC's territory has over 6,200 MW of generation, serving at most 2,100 MW of peak load. A majority of WALC's generation is federal hydroelectric facilities, with the balance consisting of thermal generation owned and operated by independent power producers. WALC also operates an extensive transmission network within its footprint, and is interconnected with APS, SCE, and nine other balancing areas.

- **San Onofre Nuclear Generating Station**

SONGS is a two-unit nuclear generation facility capable of producing approximately 2,200 MW of power, and is located north of San Diego.[25] SONGS produces approximately 19% of the power used by SCE customers and 25% of the power used by SDG&E customers. SONGS is jointly owned by SCE (78.21%), SDG&E (20%), and the City of Riverside (1.79%). SCE, as TO and GO, is responsible for ensuring the safe and reliable operation of SONGS within the grid.

- **California Independent System Operator**

---

[25] SONGS is currently in the midst of an extended outage. According to a March 2012 press release by CAISO, if both SONGS units remain offline for the summer, "San Diego and portions of the Los Angeles Basin may face local reliability challenges." http://www.caiso.com/Documents/SummerGridOutlook Complicated-PossibleExtendedOutage-NuclearPowerPlant.pdf.

CAISO runs the primary market for wholesale electric power and open-access transmission in California, and manages the high-voltage transmission lines that make up approximately 80% of California's power grid. CAISO operates its market through day-ahead and hour-ahead markets, as well as scheduling power in real time as necessary. Among other registrations, CAISO is PC and BA for most of California, including the city of San Diego. It also acts as TOP for several entities within its footprint, including SDG&E and SCE. CAISO likewise engages in modeling and planning functions in order to ensure long-term grid reliability, as well as identifying infrastructure upgrades necessary for grid function.

- **San Diego Gas and Electric**

SDG&E is a utility that serves both electricity and natural gas to its customers in San Diego County and a portion of southern Orange County, and is the primary utility for the city of San Diego. SDG&E owns relatively little generation—approximately 600 MW—although generation owned by others in its footprint brings the total generation capacity of the area above 3,350 MW. Peak load for the area can exceed 4,500 MW in the summer. SDG&E also operates an extensive high-voltage transmission network at the 500, 230, and 138 kV levels. SDG&E, operating as a TOP within CAISO's BA footprint, has delegated part of its responsibilities as a TOP to CAISO.

- **Comisión Federal de Electricidad – Baja California Control Area**

CFE is the only electric utility in Mexico, servicing up to 98% of the total population. CFE's Baja California Control Area is not connected to the rest of Mexico's electric grid but is connected to the Western Interconnection. CFE's Baja California Control Area covers the northwest corner of Mexico, including the cities of Tijuana, Rosarito, Tecate, Ensenada, Mexicali, and San Luis Rio Colorado. CFE's Baja California Control Area operates transmission systems at the 230, 161, 115, and 69 kV levels, and owns 2,039 MW of gross generating capacity and the rights to a 489 MW independent power producer within the Baja California Control Area. CFE's Baja California Control Area had a net peak load of 2,184 MW for summer 2010. CFE's Baja California Control Area is connected at the 230 kV level with SDG&E through two transmission lines on WECC Path 45. CFE functions as the TO, TOP, and BA for its Baja California Control Area under the oversight of WECC RC. For the remainder of this report, "CFE" refers only to its Baja California Control Area.

- **Southern California Edison**

SCE is a large investor-owned utility which provides electricity in central, coastal, and southern California. SCE is a wholly-owned subsidiary of Edison International, which is also based in California. Among other NERC registrations, SCE operates as a TOP within CAISO's BA footprint, and has delegated part of its responsibilities as a TOP to CAISO. SCE is also registered as TP, and is responsible for the reliability assessments of the SONGS separation scheme. SCE owns 5,490 circuit miles of transmission lines, including 500, 230, and 161 kV lines. SCE also operates a subtransmission system of 7,079 circuit miles at the 115, 66, 55, and 33 kV levels. Of the affected entities, SCE is interconnected with APS, IID, and SDG&E at various transmission voltage levels. SCE owns over 5,600 MW of generation, including a majority share in SONGS, and its peak load exceeds 22,000 MW. Along with SONGS staff, SCE is responsible for the safe and reliable operation of the nuclear facility.

Interconnected Operations

The September 8th event exemplifies the interconnected operations of three parallel transmission corridors through which power flows into the area where the blackout occurred. Typically, BAs, through dispatch, balance the flows on these corridors so that no one corridor experiences overloads in an N-1 situation, but this did not happen on September 8th.

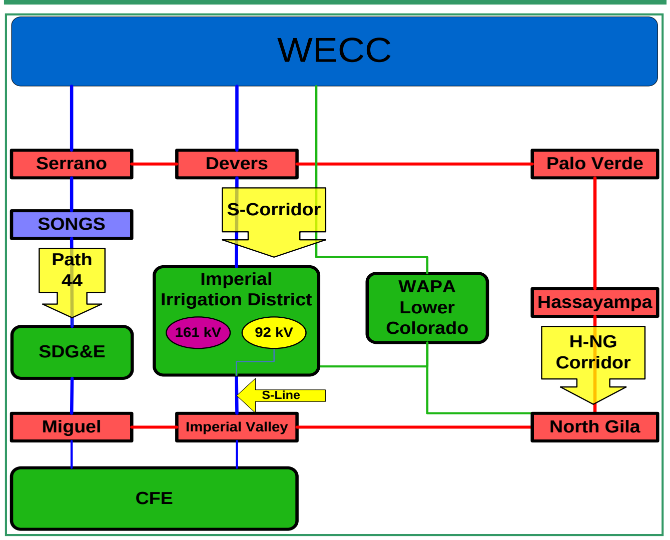
The first transmission corridor consists of the 500 kV H-NG, which is one of several transmission lines forming Path 49 ("East of River"). Along with two 500 kV lines, one from North Gila to Imperial Valley and another from Imperial Valley to Miguel, they form the SWPL. The majority of the SWPL is geographically parallel to the United States-Mexico border. The SWPL meets the SDG&E and IID systems at the Imperial Valley substation. This is shown as the "H-NG Corridor" on ***Figure 3***, on the next page.

The second corridor is Path 44, also known as "South of SONGS," operated by CAISO. This corridor includes the five 230 kV lines in the northernmost part of the SDG&E system that connect SDG&E with SCE at SONGS.

The third transmission corridor, shown as the "S Corridor" on Figure 3, consists of lower voltage (230, 161 and 92 kV) facilities operated by IID and WALC in parallel with those of SCE, SDG&E, and APS. The only major interconnection between IID and SDG&E is through the 230 kV "S" Line, which connects the SDG&E/IID jointly-owned Imperial Valley Substation (operated by SDG&E) to IID's El Centro Switching Station. The S Line interconnects the southern IID system with SDG&E and APS at Imperial Valley, which is also a terminus for the SWPL segment from Miguel and the SWPL segment from North Gila. WALC is connected to the SCE system and the rest of the Western Interconnection by 161 kV ties at Blythe, to IID by the 161 kV tie between WALC's Knob and IID's Pilot Knob substations, and to APS by a 69 kV tie via Gila at North Gila.

The eastern end of the SWPL, which terminates at APS's Hassayampa hub, is connected to SCE via a 500 kV line that connects APS's Palo Verde and SCE's Devers substations. The northern IID system is connected to SCE's Devers substation via a 230 kV transmission line that connects from Devers to IID's CV substation. These connections, along with SDG&E's connection to SCE via Path 44's terminus at SONGS, make the SWPL, Path 44, and IID's and WALC's systems operate as electrically parallel transmission corridors.[26] The following simplified diagram illustrates the interconnected nature of these three parallel corridors. Red lines represent 500 kV, blue lines represent 230 kV, and green lines represent 161 kV.

Figure 3: Three Parallel Corridors



[26] Power transfers from APS to SDG&E and CFE generally flow across the SWPL, but, due to parallel path flows, also known as loop flows, some of the power transfers flow through IID's and WALC's systems. Loop flow refers to power flow along any transmission paths that are in parallel with the most direct geographic or contract path.

III. SEQUENCE OF EVENTS[27]

The 11 minutes of the disturbance are divided into seven phases, as highlighted in ***Figure* 4**, on the next page. This figure displays the progressive loading of the five 230 kV tie lines from SCE north of San Diego that form Path 44. This section describes how the loss of various elements during an 11-minute period combined to exceed the 8,000 amp setting on the SONGS separation scheme. After sustained loading on Path 44 above 8,000 amps, the SONGS separation scheme operated. Once the SONGS separation scheme operated, San Diego and IID, CFE, and Yuma, Arizona, blacked out in less than 30 seconds. This section is divided into subsections for each phase, including the key events during the phase, their causes and effects, and, where relevant, what the affected entities knew and did not know as the events were unfolding. Each section begins with a brief summary. A final subsection describes restoration efforts after the blackout.

A set of graphics is included at the end of each phase to demonstrate the effect of the events during the phase. The first graphic in each set depicts the aggregate loading in amps on the five South of SONGS lines.[28] The bottom portion of the graphic shows all of the phases, while the majority of the graphic shows an expanded view of the phase being discussed. The second graphic in each set represents the loading on key facilities after each phase. The third graphic in each set shows how power flows redistributed through Arizona, Southern California, and Mexico after each phase. Phases 6 and 7 have multiple power flow graphics. Phases 1 and 7 include only the second and third type of graphics.

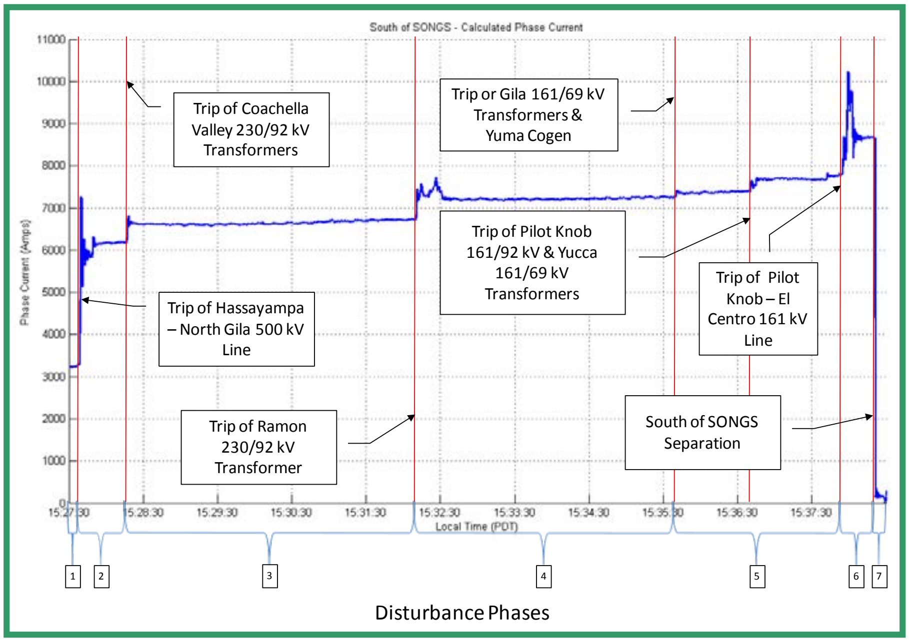
---

27 All times are in Pacific Daylight Time (PDT) unless otherwise noted. Times are listed to millisecond (three decimal places) or tenth-of-second (decimal place) accuracy when possible. If milliseconds or tenth-of-seconds are not listed, the event is reconciled to the nearest second.

28 Path 44 flows (complex power in volt amperes, current in amps) were calculated from SONGS PMU data. Those readings differ somewhat from disturbance monitoring equipment that was unavailable until completion of the inquiry's analysis. The differences are explained by variances in how some minor auxiliary loads are measured and in measurement equipment tolerances.

The following figure shows all seven phases of the disturbance.

Figure 4: Seven Phases of the Disturbance



A. Phase 1: Pre-Disturbance Conditions

Phase 1 Summary:

- Timing: September 8, 2011, before H-NG trips at 15:27:39
- A hot, shoulder season day with some generation and transmission maintenance outages
- Relatively high loading on some key facilities: H-NG at 78% of its normal rating, CV transformers at 83%
- 44 minutes before loss of H-NG, IID's RTCA results showed that the N-1 contingency loss of the first CV transformer would result in an overload of the second transformer above its trip point
- An APS technician skipped a critical step in isolating the series capacitor bank at the North Gila substation

September 8, 2011, was a relatively normal, hot day in Arizona, Southern California, and Baja California, Mexico, with heavy power imports into Southern California from Arizona. In fact, imports into Southern California were approximately 2,750 MW, just below the import limit of 2,850 MW. September is generally considered a "shoulder" season, when demand is lower than peak seasons and generation and transmission maintenance outages are scheduled. By September 8th, entities throughout the WECC region, including some of the affected entities, had begun generation and transmission outages for maintenance purposes. For example, on September 8th maintenance outages included over 600 MW of generation in Baja California.[29] and two 230 kV transmission lines in SDG&E's territory. However, there were no major forced outages or major planned transmission outages that would result in a reduction of the SOLs in the area.

- **Pre-Disturbance Conditions in IID**

Despite September being considered a shoulder month, temperatures in IID's service territory reached 115 degrees on September 8th.[30] IID's load headed toward near-peak levels of more than 900 MW, which required it to dispatch local combustion turbine generation in accordance with established operating procedures. Prior to the event, loading on IID's CV transformers reached approximately 125 megavolt amperes (MVA) per transformer, which is approximately 83% of the transformers' normal limit. Loading on IID's Ramon transformer was 153 MVA, which is approximately 68% of its normal limit.

IID's S Line ties IID to SDG&E, and through SDG&E, to generation in Mexico at La Rosita. It also ties CFE and IID, through SDG&E's La Rosita international transmission line. Before the event, IID was importing power on the S Line, and thus power was flowing northward from the jointly owned Imperial Valley substation to IID's El Centro substation. Flows on the S Line would reverse multiple times during the event. When power flowed on the S Line from south to north, the implication was that IID was supplied radially through SDG&E. Throughout the event, as power flowed from north to south, the implication was that flows intended for SDG&E and/or CFE were moving through IID's system. Eventually, in Phase 6, south to north flows on the S Line would activate a RAS that would ultimately trip more than 400 MW of generation at La Rosita and the S Line, thereby worsening the loading on Path 44.

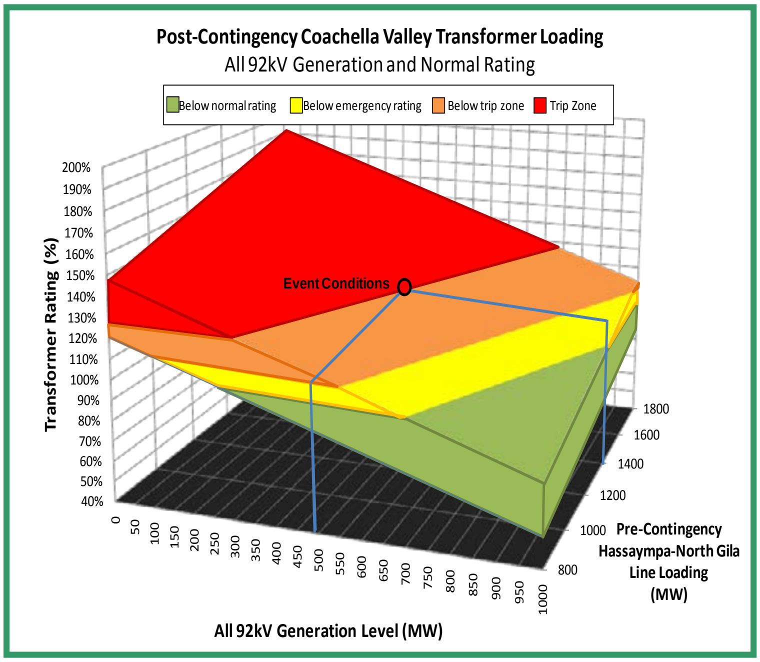
Forty-four minutes prior to the loss of H-NG on September 8, 2011, IID's RTCA results showed that the N-1 contingency loss of the first CV transformer would result in an overload of the second transformer above its trip point. The IID operator was not actively monitoring the RTCA results and, therefore, was not alerted to the need to take any corrective actions. At the time of the event, IID operators did not keep the RTCA

[29] The generation was known as Termoelectrica de Mexicali, and will be hereafter referred to as "TDM." It is also shown as "TDM" on the Map of Affected Entities.

[30] According to IID, the temperature in El Centro, California reached 115 degrees on September 8, 2011.

display visible, and RTCA alarms were not audible. By reducing loading on the CV transformers at this pre-event stage, the operator could have mitigated the severe effects on the transformers that resulted when H-NG tripped. Since the event, IID has required, and now requires, its operators to have RTCA results displayed at all times. The loading on IID's CV transformers was pivotal to this event. Loading on the CV transformers is influenced by: (1) the pre-contingency flow on H-NG; (2) load and generation in IID's 92 kV network; (3) flow on the S Line; and (4) to a lesser extent, generation connected to the Imperial Valley substation. See Figure 5, below.

Figure 5: Post-Contingency CV Transformer Loading Based on All IID 92 kV Generation



▪ Pre-Disturbance Conditions in CFE

At 15:07 CFE's Presidente Juarez Unit 11 tripped, which required CFE to activate its Baja California Control Area contingency reserves to restore its ACE. At 15:15 PDT CFE returned its ACE to where it had been before the unit tripped. Although still complying with the spinning reserve requirements, CFE was short on non-spinning reserve, with all of its available resources in use or already deployed.

- ### Pre-Disturbance Focus of WECC RC

Prior to the event, WECC RC operators were monitoring unscheduled flow on several paths in Northern California. WECC RC did not view any of the scheduled transmission or generation outages as significant. As illustrated by the chart below, two minutes before the event (at 15:25), major paths in the blackout area were operating below their Path ratings:

Major Paths in the Blackout Area	Established Path Ratings/Flow Limits	Path Loadings in MW and %
500 kV H-NG (Part of Corridor 1 into blackout area)	1,800 MW.[31]	1,397 MW 78%
Path 44 (Corridor 2 into blackout area)	2,200 MW.[32]	1,302 MW 59%
230 kV S Line (Part of Corridor 3 into blackout area)	239 MW	90 MW 38%
SDG&E Import SOL	2,850 MW	2,539 MW 89%
SDG&E to CFE Path 45	800 MW S-N; 408 MW N-S	241 MW N-S 60%

- ### Pre-Disturbance Conditions in APS

APS manages H-NG, a segment of the SWPL. At 13:57:46, the series capacitors.[33] at APS's North Gila substation were automatically bypassed due to phase imbalance protection. APS sent a substation technician to perform switching to isolate the capacitor bank. The technician was experienced in switching capacitor banks, having performed switching approximately a dozen times. APS also had a written switching order for the specific H-NG series capacitor bank at North Gila. After the APS system operator and the technician verified that they were working from the same switching order, the operator read steps 6 through 16 of the switching order to the technician. The technician repeated each step after the operator read it, and the operator verified the

[31] The limit of H-NG is a portion of the rating of Path 49. The inquiry determined that the limit is approximately 1,800 MW.

[32] With one segment of the SWPL out, the limit increases to 2,500 MW.

[33] A series capacitor is a power system device that is connected in series with a transmission line. It increases the transfer capability of the line by reducing the voltage drop across the line and by increasing the reactive power injection into the line to compensate for the reactive power consumption. In simple terms, a 50% series compensated line means it has the equivalent of 50% of the electric distance (or impedance) of the otherwise uncompensated line.

technician had correctly understood the step. The technician then put a hash mark beside each of steps 6 through 16 to indicate that he was to perform those steps. The technician did not begin to perform any of steps 6 through 16 until after all steps had been verified with the system operator.

The technician successfully performed step 6, verifying that the capacitor breaker was closed, placing it in "local" and tagging it out with "do not operate" tags. However, because he was preoccupied with obtaining assistance from a maintenance crew to hang grounds[34] for a later step, he accidentally wrote the time that he had completed step 6 on the line for step 8. For several minutes, he had multiple conversations about obtaining assistance to hang the grounds. He then looked back at the switching order to see what step should be performed next. His mistake in writing the time for step 6 on the line for step 8 caused him to pick up with step 9, rather than step 7.[35] Thus, he skipped two steps, one of them the crucial step (step 8) of closing a line switch to place H-NG in parallel with the series capacitor bank. This step would bypass the capacitor bank, resulting in almost zero voltage across the bank and virtually zero current through the bank. Because he skipped step 8, when he began to crank open the hand-operated disconnect switch to isolate the capacitor bank, it began arcing under load.[36] He could not manage to toggle the gearing on the switch to enable its closure, so he stayed under the arcing 500 kV line, determined to crank open the switch far enough to break the arc, thereby preventing additional damage to the equipment. ***Figure* 6**, on the next page, is a schematic of the APS series capacitor bank, showing steps seven through nine.

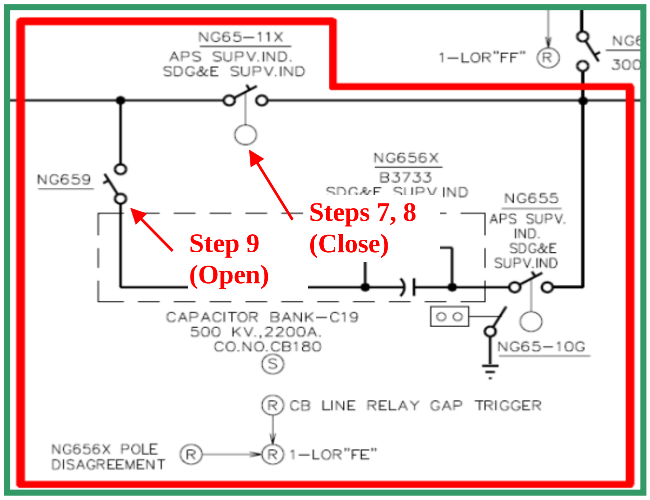
---

[34] Grounds are temporary protective connections that are run from conductive parts of lines, structures, and equipment, to earth or some other grounding system that substitutes for earth. If the isolated equipment is accidentally energized, grounds are intended to: (1) limit the voltage rise at the worksite to a safe value; and (2) provide a pathway for fault current to flow, thereby allowing upstream protective devices to trip.

[35] In human performance analysis, this is known as a "place keeping" error, by failing to physically mark steps as they are completed.

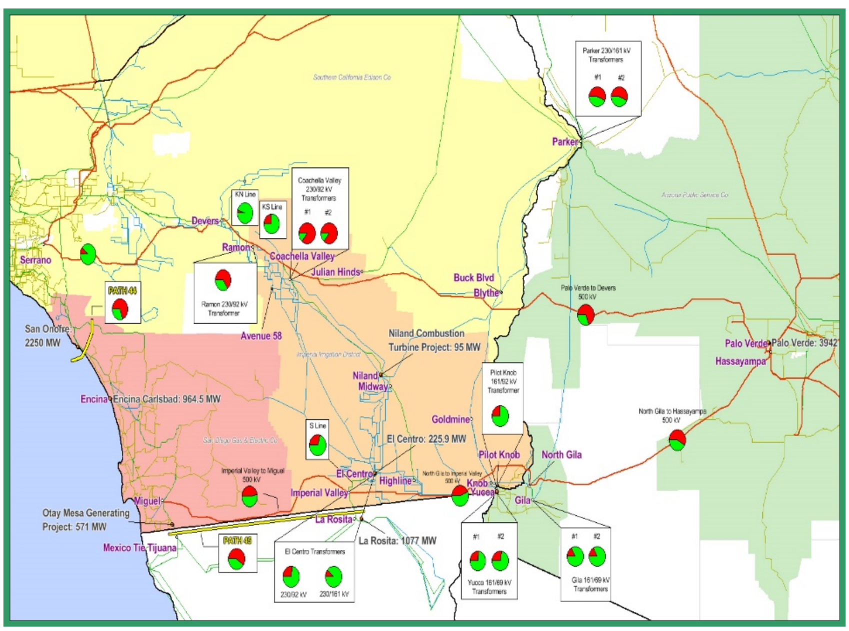
[36] An electric arc is a luminous discharge of current that is formed when a strong current jumps a gap in a circuit.

Figure 6: APS Series Capacitor Bank



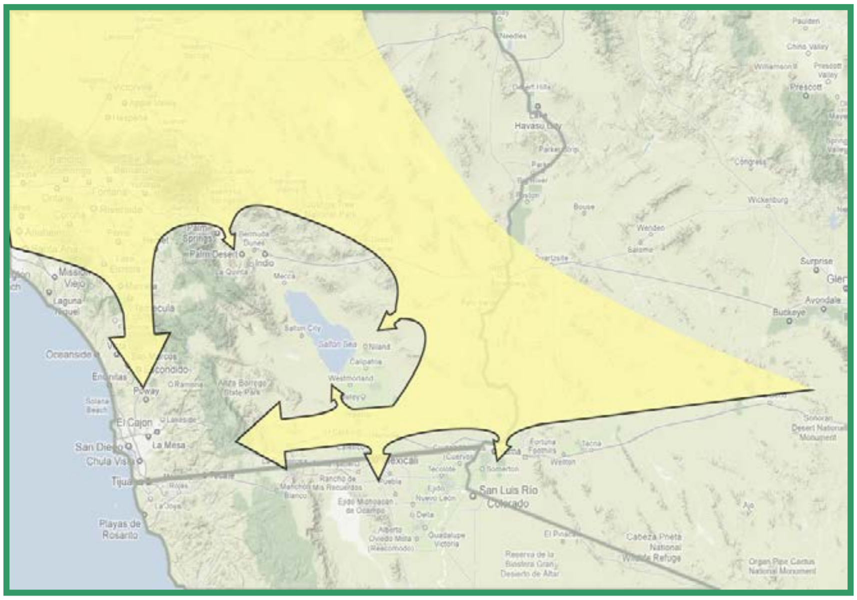
Phase 1 Graphics[37]

Pre-disturbance (000)



37 For the dial graphics shown here, green indicates available capacity on the facility, red indicates that the facility is fully loaded to its normal limit, blue indicates the amount by which the facility is overloaded, and gray indicates that the facility has tripped or load has been lost. For the power flow graphics, black borders indicate islanding, and gray areas bounded by black are those where load was lost.

15:27:00



B. Phase 2: Trip of the Hassayampa-North Gila 500 kV Line

Phase 2 Summary:

- Timing: 15:27:39 to 15:28:16, just before CV transformer No. 2 trips
- H-NG trips due to fault; APS operators believe they will restore it quickly and tell WECC RC
- H-NG flow redistributed to Path 44 (84% increase in flow), IID, and WALC systems
- CV transformers immediately overloaded above their relay setting
- At end of Phase 2, loading on Path 44 at 5,900 out of 8,000 amps needed to initiate SONGS separation scheme

At 15:27:39, the arc that had developed on each phase of the disconnect switch lengthened as the switch continued to open, to the point where two phases came into contact. This caused H-NG to trip to clear this phase-to-phase (A to C) fault. The high-speed protection system correctly detected the fault and tripped the line in 2.6 cycles (43 milliseconds). After discussion with the technician, APS operators erroneously believed that they could return the line to service in approximately 15 minutes, even though they had no situational awareness of a large phase angle difference caused by the outage. More time would have been needed to redispatch generation to reduce the phase angle difference to the allowed value. APS system operators informed CAISO, Salt River Project (SRP), and WECC RC that the line would be reclosed quickly, even though they were unaware that this was not possible because of the large phase angle difference that existed between Hassayampa and North Gila. The inquiry's simulation indicates that the post-contingency angular difference was beyond the allowed North Gila synch-check relay reclosing angle setting of 60 degrees, and there would not have been adequate generation for redispatch to reduce the phase angle difference to within the allowed value. APS operators were only able to see the angular difference on EMS displays after isolating the North Gila capacitor bank and re-energizing H-NG from the Hassayampa substation (before closing at North Gila).

H-NG, which has a flow limit of 1,800 MW[38] with a 30 minute emergency rating of 2,431 MW, was carrying 1,391 MW flowing from east to west along the SWPL at the time of the trip. As a result of the line trip, flows redistributed across the remaining lines into the San Diego, Imperial Valley, and Yuma areas. The IID and WALC systems, located between the two parallel high voltage Paths, were forced to carry approximately 23% of the flow that had initially been carried by H-NG. The majority of the flow diverted to Path 44, as discussed below.

Immediately after the loss of H-NG, the loading on both of IID's CV transformers increased to 130% of their normal rating and 118.5% of their emergency rating. The time overcurrent relays on the CV transformers picked up because the current flow was above the overcurrent relay setting, and began timing according to their very inverse[39] time delay. The CV transformers would both trip within 40 seconds of the loss of H-NG. At the same time, loading on IID's Ramon 230/92 kV transformer increased to 94% of its normal rating and 85% of its emergency rating. Three seconds after the loss of H-NG, SCADA metering for the CV transformer banks stopped recording accurate readings due to remote terminal unit (RTU) exceeding maximum scale. IID and WECC RC no longer had accurate information about or situational awareness of the loading on these important transformers.

IID also experienced increased loading on several of its 161 kV lines immediately after the loss of H-NG: Blythe-Niland and Knob-Pilot Knob loading increased by 49% and 55%, respectively. Flows on IID's S Line reversed from south to north (SDG&E to IID) to north to south (IID to SDG&E) during this phase of the event, indicating that

[38] *See* footnote 31, *supra*.

[39] "Very inverse" describes the time/current characteristic of the relays' time delay which is inversely proportional to the current magnitude sensed by the relay. That is, the greater the current, the less time before the relay will trip.

flows intended for SDG&E were being routed through IID's 161 and 92 kV systems. While IID was aware of the flow changes on the S Line, it was unable to see the loss of H-NG in real time.

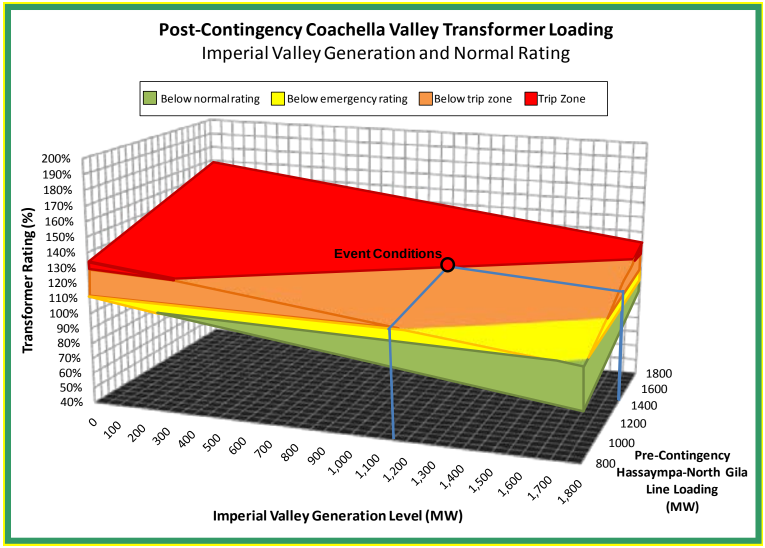
Flows on WALC's Gila 161/69 kV transformers increased from approximately 12 MVA to 60 MVA, still well below their normal limits of 75 MVA each, but indicative of the sudden increase in flows on WALC's system just after the loss of H-NG. WALC also experienced significant voltage drops on its 161 kV system, particularly at Blythe (6.9% drop) and Kofa (6.7% drop) substations, due to the increased flows on that system.

The loss of H-NG interrupted the southern 500 kV path into San Diego. The majority of the flow diverted to the northern entry to SDG&E, Path 44. Flow on Path 44 increased by approximately 84%, from 1,293 MW to 2,362 MW. This flow equates to a tie current of 5,900 amps relative to the 8,000 amps required to initiate the SONGS separation scheme.

Because so much of the flow on H-NG was intended for San Diego, the inquiry considered whether increasing internal generation in SDG&E's area would have avoided the cascading outages.[40] ***Figure 7***, on the next page, illustrates post-contingency loading on the CV transformers based on pre-contingency loading on H-NG and the generation level at IID's and SDG&E's jointly owned Imperial Valley substation. The red area on the graph indicates the large zone in which loading below H-NG's 1,800 MW SOL would load the CV transformers above their trip point. This area demonstrates the non-secure N-1 operating point of the CV transformers. It shows that the operating conditions that would reduce the loading on the transformer are: increased generation at Imperial Valley, reduced flow on H-NG before it tripped, or both. For example, the graph indicates that for the same amount of transfer on H-NG, additional generators connected at Imperial Valley would reduce the post-contingency loading on the CV transformers.

[40] The inquiry's analysis is not intended to suggest specific generation adjustments that could have been made by specific entities on September 8, 2011, but rather to show the extent to which the affected entities are interdependent.

Figure 7 : Post-Contingency CV Transformer Loading Based on Imperial Valley Generation



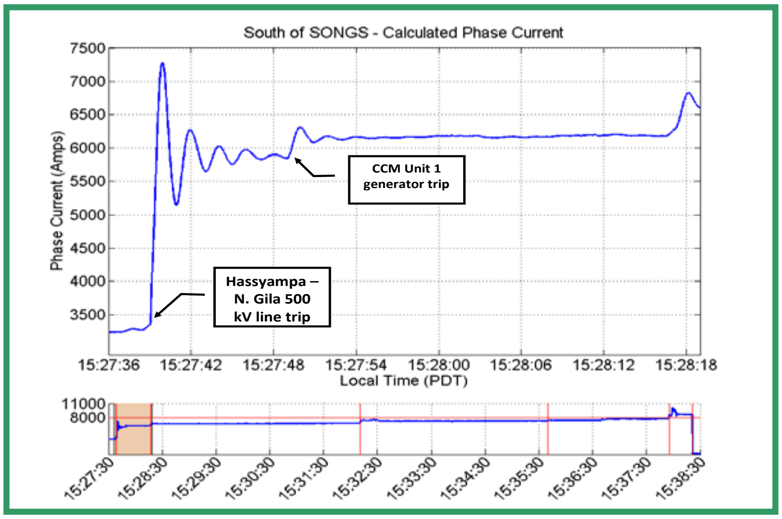
In general, adding generation in San Diego, CFE, or Imperial Valley and backing down generation in APS's system (east of Path 49) would reduce the loading on IID's 92 kV system for the loss of H-NG. For example, an additional 600 MW of generation at Imperial Valley and a reduction of generation in APS's system by the same amount would have reduced the pre-contingency loading on H-NG by 20% and improved the post-contingency voltage in WALC's Blythe area by approximately 4%. Under this condition, the loading on the CV transformers for the loss of H-NG would be approximately 111% of their normal rating (166 MVA), well below their trip setting of 127%. This is a further demonstration of the importance of including all facilities when deriving SOLs.

After seeing the alarm for the loss of H-NG, the WECC RC operator promptly called the line's operator, APS. APS told WECC RC it could get H-NG restored within minutes. While WECC RC was monitoring Rated Paths, it took no action specific to Path 44, believing it would take five or ten minutes for APS to restore H-NG. As the entire event took only 11 minutes, WECC RC did not issue any directives in connection with the loss of H-NG.

Shortly after H-NG tripped, at 15:27:49, one of the combustion turbines at CFE's Central La Rosita substation tripped while producing 156 MW. This trip may have been triggered by transients.[41] caused by the initial fault at North Gila and subsequent trip of H-NG. Loss of this unit further increased the flow on Path 44, raising the current to 6,200 amps out of the 8,000 needed to initiate the SONGS separation scheme. However, the La Rosita trip alone was not significant in causing the cascading that followed.[42] CFE was also unaware in real time that H-NG had tripped. After losing the Central La Rosita unit, CFE was unable to recover its ACE with its own resources, and at 15:30, it requested 158 MW of emergency assistance from CAISO for the remainder of the hour.

Phase 2 Graphics

South of SONGS – Calculated Phase Current

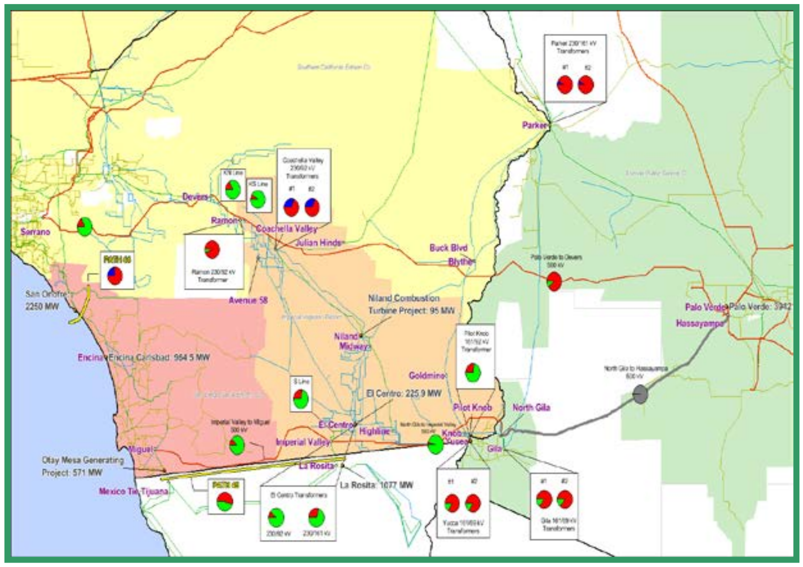


---

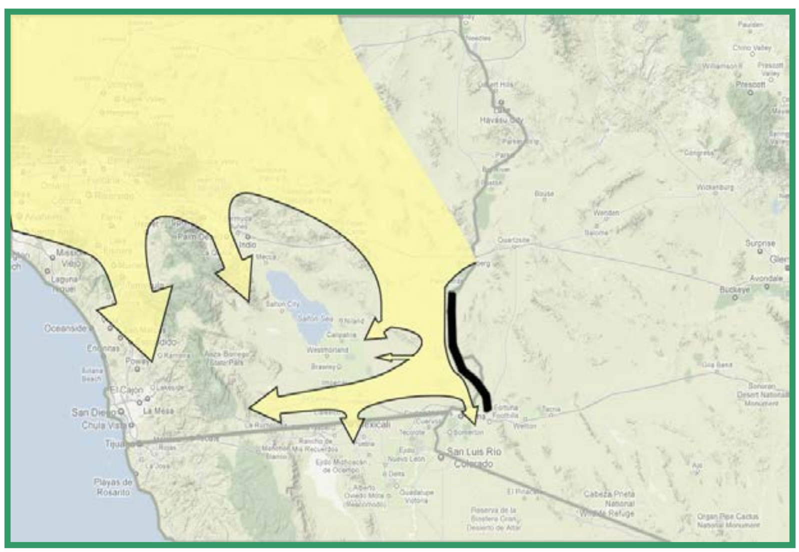
[41] *See* footnote 21. CFE stated that the trip was triggered by transients.

[42] The Modeling and Simulation team conducted a "what if" simulation and determined that, even without the inadvertent tripping of 160 MW of generation at La Rosita, the overloads and ensuing blackout would still have occurred.

15:27:39 – The Hassayampa- North Gila 500 kV line tripped.



15:27:40



C. Phase 3: Trip of the Coachella Valley 230/92 kV Transformer and Voltage Depression

Phase 3 Summary:

- Timing: 15:28:16, when CV transformer bank No. 2 tripped, to just before 15:32:10, when Ramon transformer tripped
- Both CV transformers tripped within 40 seconds of H-NG tripping
- IID knew losing both CV transformers would overload Ramon transformer and S Line connecting it with SDG&E
- Severe low voltage in WALC's 161 kV system
- At end of Phase 3, loading on Path 44 at 6,700 amps out of 8,000 needed to initiate SONGS separation scheme

At 15:28:16, less than a minute after H-NG tripped, IID's CV transformer bank No. 2 tripped on the 230 kV side. The CV overload protection relays detected an overload immediately after H-NG was lost. The overloads were caused by through-flows on IID's 92 and 161 kV systems which parallel APS's 500 kV system. The normal ratings for these transformers are 150 MVA, but immediately after H-NG tripped, each CV transformer was carrying more than 191 MVA. The relays were set to trip at approximately 127%[43] of the transformers' normal ratings, or 191.2 MVA at nominal voltage. The inverse time relays took 37.5 seconds to trip bank No. 2 and 38.2 seconds to trip bank No. 1. Thus, CV bank No. 1 tripped only 677 milliseconds after bank No. 2, again on the 230 kV side. Although the primary winding or high side voltages of the CV transformers are 230 kV, the banks were not considered as elements of the BES because their secondary winding or low side voltages are below 100 kV. As discussed in detail in Section IV, because these transformers and the underlying 92 kV system were not classified as elements of the BES, IID, neighboring TOPs, and WECC RC did not assess the impact of critical external contingencies on overloading the CV banks, the effect of losing the CV banks and the subsequent impact on the Ramon bank, and, finally their overall adverse effect on BPS reliability.

IID was aware of the potential for local cascading if the CV transformers tripped. IID's next-day plan for September 8, 2011, which was not based on updated studies, indicated that if both CV transformers tripped,[44] the Ramon 230/92 kV transformer would trip and the S Line tie with SDG&E would overload to 109% of its normal rating. The next-day plan also indicated that this overloading, in turn, would result in tripping generation because the S Line RAS trips generation supplied to Imperial Valley when the S Line loads to 108% of its normal rating. IID's next-day mitigation plan for loss of the CV transformers required starting turbines at Coachella and Niland and asking CAISO to

[43] IID's transformer protection philosophy specifies trip settings at 120% of normal ratings. IID chose the closest available relay tap, which was approximately 127% of the normal rating.

[44] This contingency scenario had nothing to do with H-NG tripping. IID's studies did not show any effect on the CV banks resulting from the loss of H-NG.

redispatch generation to relieve the S Line. This was a post-contingency mitigation plan. But after the event, IID's operator admitted that if the CV transformers tripped on overload, he would have "very little time to mitigate the Ramon [transformer], if at all." Even the quickest-starting turbines take about 10 minutes to start and ramp to full load, but IID effectively had only four minutes before the Ramon transformer would trip, after the loss of the CV transformers.

The loss of the CV banks caused flows on the S Line between SDG&E and IID to again reverse direction. Because its load exceeded internal generation, IID began pulling power from SCE through SDG&E due to the loss of key facilities in IID's northern system. The tripping of the second CV bank also open-ended the Coachella Valley-Ramon 230 kV "KS" Line (at CV), which was carrying about 41 MVA. This further increased loading on the Mirage-Ramon 230 kV line and through-flow from IID's 230 kV collector system through Devers, but had little effect on the overall disturbance. By 15:31:35, IID's operators switched in 92 kV capacitor banks at Avenue 42, Avenue 58, and Highline due to low voltage.

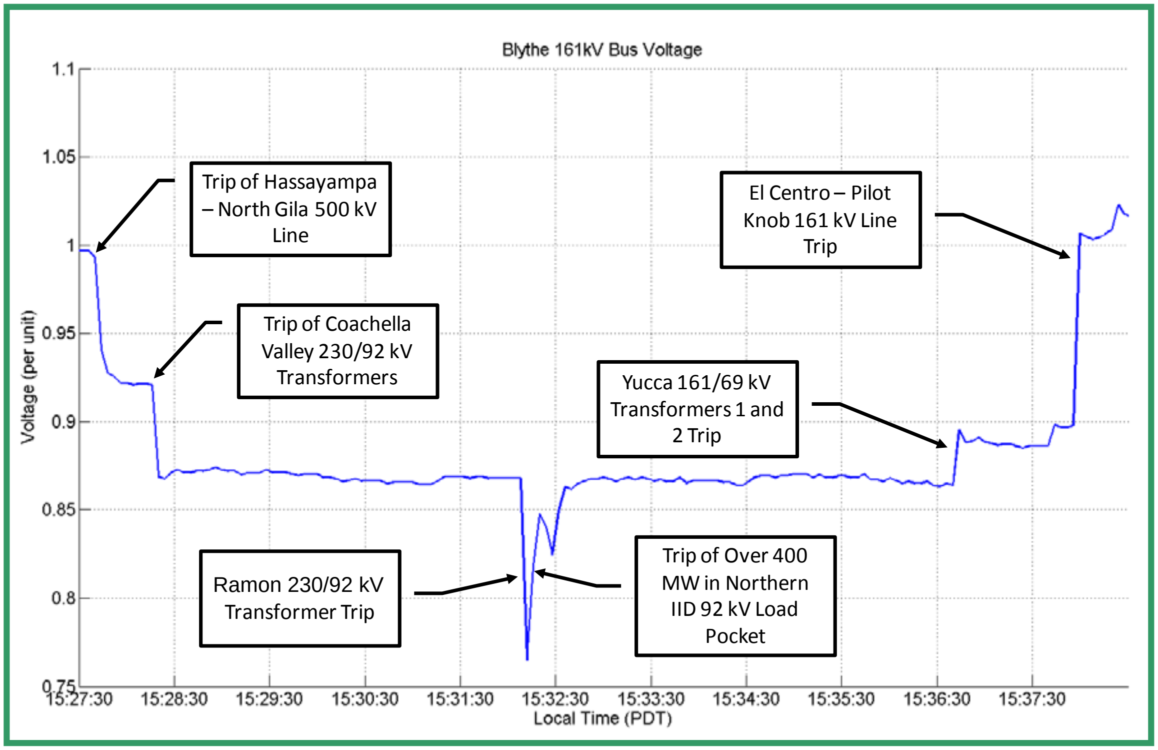
The loss of IID's two CV transformers caused the aggregate current on Path 44 to increase from 6,200 amps to 6,600 of the 8,000 amps necessary to trigger the SONGS separation scheme. However, by the end of this Phase aggregate Path 44 current reached 6,700 amps.

The loss of the CV banks caused a severe voltage depression on the WALC 161 kV system south of Blythe. During this period, loads in that area (largely irrigation pumps) were highly susceptible to motor stalling, which can create additional reactive demand and exacerbate transmission loading, both of which contribute to additional voltage decline. See ***Figure* 8**, on the next page. At 15:28:18, the Blythe 161 kV bus alarmed at 142 kV (0.882 per unit).[45] WALC continued to experience severe low voltage on its 161 kV system until the S Line tripped at 15:38:02.4.

---

[45] Other alarms and low voltage readings followed throughout WALC's system one to nine seconds later, including the Parker-Kofa 161 kV line, which alarmed for overload at 169 MVA (167 MVA rating); Kofa 161 kV bus voltage recorded at 143 kV (0.888 per unit); Knob 161 kV bus voltage recorded at 142 kV (0.882 per unit); Parker 161 kV bus voltage recorded at 149 kV (0.925 per unit); Gila and Goldmine 161 kV bus voltages recorded at 144 kV (0.894 per unit); and Parker 230 kV bus voltage recorded at 222 (0.965 per unit).

Figure 8: Blythe 161kV Voltage



On September 8, 2011, CAISO had partial visibility of IID's system, but could not see that the CV banks had tripped. Prior to the event CAISO and IID had been working together to increase their mutual visibility and those efforts are continuing. Currently, CAISO receives loading data from the 230 kV side of the CV transformers.

Despite the fact that it did not consider the CV banks to be part of the BES, WECC RC does observe much of IID's 92 kV system in real time, including the CV banks. The WECC RC operator did notice the CV transformers trip, but he was focused on when APS would return H-NG to service.

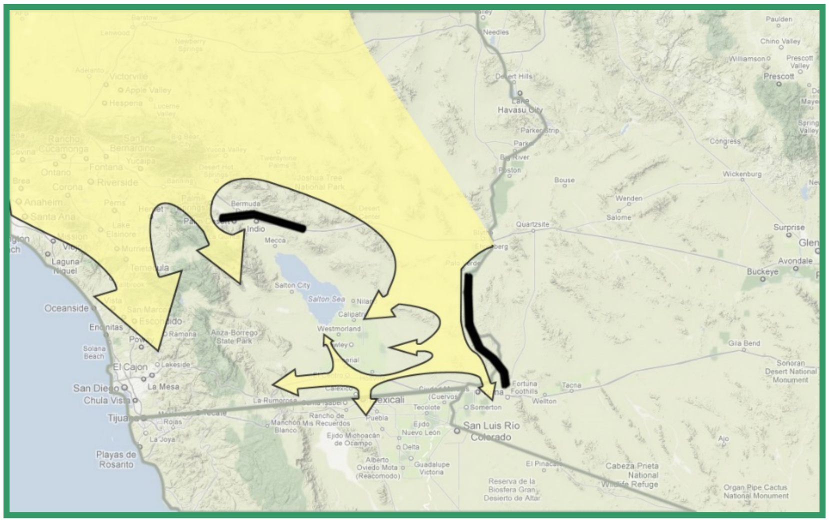
15:28:18



D. Phase 4: Trip of Ramon 230/92 kV Transformer and Collapse of IID's Northern 92 kV System

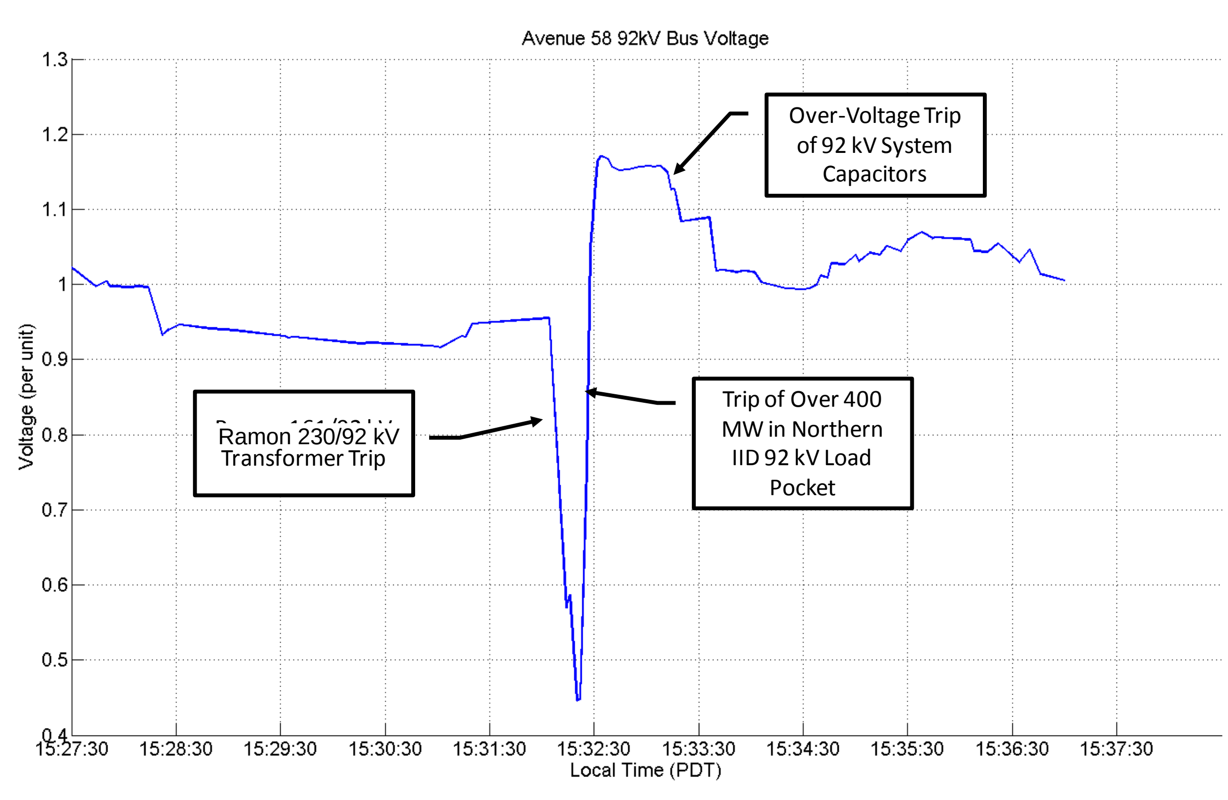
Phase 4 Summary:

- Timing: 15:32:10 to just before 15:35:40
- IID's Ramon 230/92 transformer tripped at 15:32:10, was set for 207% of its normal rating instead of its design setting of 120%, which allowed it to last approximately four minutes longer than CV transformers
- IID experienced undervoltage load shedding, generation and transmission line loss in its 92 kV system
- Path 44 loading increased from approximately 6,700 amps, to as high as 7,800 amps, and ended at around 7,200 amps (out of 8,000 needed to initiate the SONGS separation scheme)

At 15:32:10.621, less than five minutes after the trip of H-NG, IID's Ramon 230/92 kV transformer tripped on the 92 kV side. The normal rating for this transformer was 225 MVA, and its relays were set to trip above 207% of its normal rating, or 466 MVA. Before it tripped, the SCADA metering for the Ramon bank had stopped recording accurate readings due to RTUs exceeding maximum scale, just as for the CV banks. Following the loss of the CV transformers, the inverse time relays took less than four minutes to trip the Ramon transformer. IID had intended to set the Ramon transformer to trip at 120% of its normal rating. Had it been set at this level, the Ramon transformer would have tripped almost immediately after the loss of the CV transformers, approximately four minutes earlier than the time of its actual trip. IID believed that the Ramon transformer would overload beyond the trip point upon the loss of both CV transformers. Its next-day plan noted, "the Ramon Bank #1 transformer will overload and relay out of service because the overcurrent settings are set to trip at 120%." IID's next-day plan relied on a post-contingency operating philosophy of starting the Coachella Gas Turbines to mitigate overloads following the loss of the CV transformers, but the plan was unrealistic as IID would not have had time to start any additional generation between the loss of the CV transformer banks and the loss of the Ramon transformer.

Within less than one second after the loss of the Ramon transformer, automatic distribution undervoltage protection in IID's northern 92 kV system began tripping distribution feeders and shedding load. From 15:32:11 to 15:33:46, 444 MW of IID's load tripped, with nearly half of the load being shed within 10 seconds of the Ramon transformer tripping. As illustrated in ***Figure* 9**, below, the severe voltage depression following the loss of the Ramon transformer appears to have prompted a local voltage collapse within IID's northern 92 kV system, evidenced by both the steep drop-off in voltage as well as a sharp rise in reactive power flow due to motor stalling.

Figure 9: 92kV Voltage (per unit) at Avenue 58



The loss of IID's northern resources and subsequent system response caused IID to lose multiple generators connected to its 92 kV system, including IID's Niland Gas Turbine 2 (generating 45 MW), IID's CV Gas Turbine 4 (generating 20 MW), independent power producer Colmac's unit (generating 46 MW), and IID's Drop 4 Unit 2 Hydro Generator (generating 10.3 MW).

IID also began losing transmission lines. The Blythe-Niland 161 kV "F" Line, which saw increased loading during Phase 2, tripped at 15:32:13 (approximately 3 seconds after loss of the Ramon banks). Its normal rating was 165 MVA, and it was set to trip at 129% of the normal rating (212 MVA at nominal voltage) with a 3-second time delay.[46] The Niland-CV 161 kV "N" Line, carrying 83 MVA, tripped approximately 2 seconds later at 15:32:15.29 due to Zone 3 distance protection.[47]

In WALC's territory, the Blythe-Goldmine-Knob and Parker-Kofa 161 kV lines overloaded approximately four seconds after the Ramon transformer tripped, at 15:32:14, but did not trip. These lines each had a normal rating of 167 MVA, but were loaded to 177 MVA. Power flows redistributed through the Parker and Blythe areas after IID lost the Blythe-Niland line. WALC took some actions in an attempt to arrest the voltage depression it was experiencing, including a directive to start hydropower generation units Parker 3 and 4 for voltage support at 15:34:07. At the time, Parker area voltage was at 150 kV (0.932 per unit). WALC also switched in shunt capacitors on the 69 kV system at Gila and Kofa. At the time, voltage at Gila was at 65.5 kV (0.906 per unit) while Kofa was at 59 kV (0.86 per unit).

CAISO attempted to bring on generation through its exceptional dispatch[48] process to bring Path 44 back within its limit of 2,500 MW, anticipating that it had 30 minutes to do so. At 15:35, it dispatched the Larkspur No. 2 peaking unit (rated 50 MW)

---

[46] Based on the last available SCADA scan before the line tripped, the voltage at Blythe was at 123.1 kV (0.765 per unit) and the line was loaded to 172 MVA. Based on these measurements, the line was carrying 807 amps at the last time recorded; the relay was set to trip with a 3-second time delay at 762 amps.

[47] A distance relay is a relay that compares observed voltage and current on a line and operates when that ratio is below its preset value. Zone 3 relays are typically set to protect against faults that are more than one substation away from the observed line as backup protection. An appropriate time delay should be set in the relay to give the remote station relays the opportunity to operate and isolate the minimum amount of equipment necessary to clear the fault. A common issue with the application of Zone 3 relays is that they can restrict the loading on transmission lines (e.g. the N Line) during abnormal system conditions like those present on September 8th.

[48] CAISO's exceptional dispatch process involves calling on generators outside of the market automated dispatch process.

within San Diego, which has a 20-minute start-up time. Also at this time, APS began taking steps to restore H-NG by completing the bypass of the series capacitor bank.

During Phase 4, aggregate loading on the South of SONGS 230 kV transmission lines increased from approximately 6,700 amps to as high as 7,800 amps. The loading settled around 7,200 amps and remained there for the rest of Phase 4.

Phase 4 Graphics

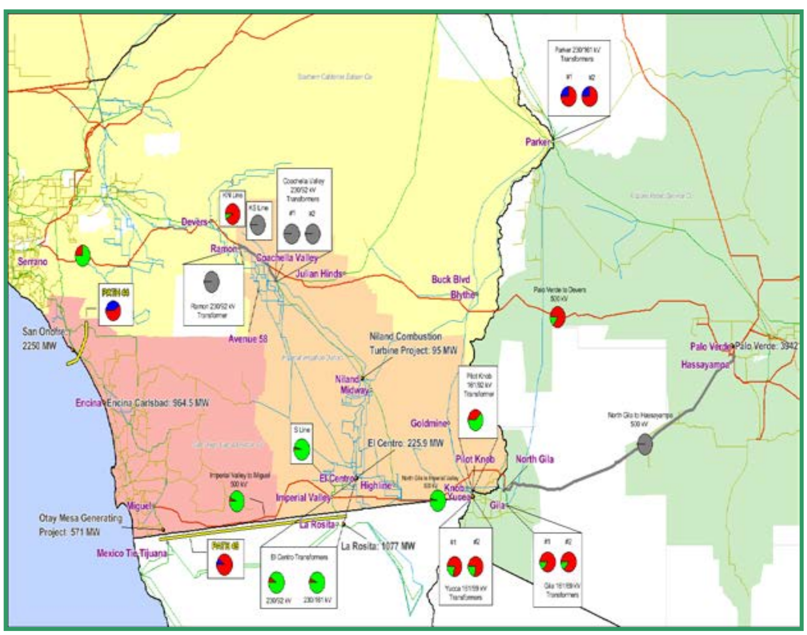
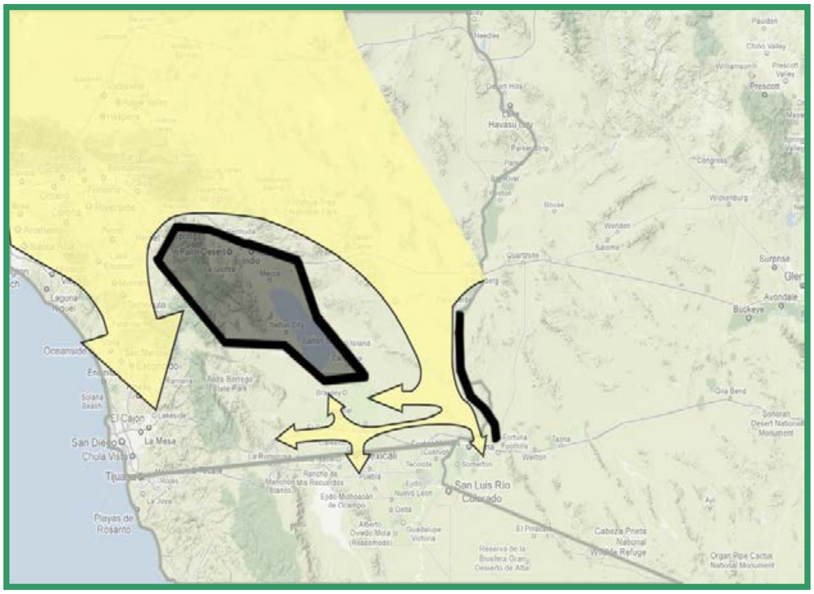
Time: 15:32:10 – The Ramon 230/92 kV transformer tripped and IID shed 444 MW of load. (110)



Time: 15:32:35



E. Phase 5: Yuma Load Pocket Separates from IID and WALC

Phase 5 Summary:

- Timing: 15:35:40 to just before 15:37:55
- The Gila and Yucca transformers tripped, isolating the Yuma load pocket to a single tie with SDG&E
- Path 44 loading increased from 7,200 to 7,400 amps after Gila transformer tripped, and ended at 7,800 amps after loss of the Yucca transformers and YCA generator (very close to the 8,000 amps needed to initiate the SONGS separation scheme)

At 15:35:40, approximately eight minutes after H-NG tripped, WALC's Gila 161/69 kV transformers tripped due to time-overcurrent protection. The two transformers are each rated 75 MVA, but the 69 kV bus section that connects the transformers to the rest of the 69 kV substation is rated 1,200 amps (143 MVA at nominal voltage), and the overcurrent protection is set accordingly at 1,200 amps. The bus was carrying 1,312 amps at the time of the trip.

One minute later, at 15:36:40, the Yucca 161/69 kV transformers 1 and 2 tripped when their common 69 kV breaker tripped due to overload protection. Bank No. 1 is owned by IID and is rated 73 MVA, and bank No. 2 is owned by APS and is rated 75 MVA. The IID Yucca generator and four out of the six APS combustion turbines connected to APS's 69 kV system were offline at the time of the event, as was the IID GT21 combustion turbine on the 161 KV side. These generators may have supported load in the area had they been in service. Almost immediately, the Pilot Knob breaker on the Pilot Knob-Yucca 161 kV "AX" transmission line, which is effectively the 161 kV breaker for the Yucca 161/69 kV transformers, received a direct transfer trip from the Yucca transformer overload protection, thereby tripping the AX Line. As a result of the loss of the Yucca and Gila transformers, the Yuma load pocket was isolated to only one tie to the SDG&E system, causing loading on each N. Gila 500/69 kV transformer bank to increase from 57 MVA to 164 MVA.

Less than one second after the Yucca transformers and AX Line tripped, at 15:35:40, the Yuma Cogeneration Associates (YCA) combined cycle plant on the Yuma 69 kV system tripped. The combustion turbine is rated at 35 MW and the heat recovery unit is rated at 17 MW, totaling 52 MW. It appears that both units were fully loaded at the time of the trip. The cause of the trip is unknown, but the loss of the YCA unit hastened the collapse of the Yuma load pocket.

Approximately one minute later, at 15:37:41, a common 161 kV breaker tripped IID's Pilot Knob 161/92 kV transformers Nos. 2 and 5 for No. 2 overload protection. The overload protection was set to trip the banks at 121% of the normal rating (37.5 MVA at nominal voltage).

At WALC's request, between 15:36:48 and 15:36:52, SCE directed Metropolitan Water District operators to drop 80 MW of pumping load attached to the Gene substation (near Parker) to improve 230 kV voltage support at Parker in an attempt to arrest declining voltages.

As it had done during Phase 4, CAISO ordered exceptional dispatch to bring Path 44 below its 2,500 MW limit. At 15:36:00, CAISO called SCE and ordered an exceptional dispatch of Larkspur Peaking Unit No. 1 (rated 50 MW), and Kearny GT2 and GT3 (each rated 59 MW) to go to full load. The Larkspur unit takes 20 minutes to start, and the Kearny units are 10-minute "quick start" peaking generators. All of these units were offline at the time, and they were unable to come online before the system collapsed.[49]

The tripping of the Gila 161/69 kV transformers caused the aggregate loading on Path 44 to increase from approximately 7,200 amps to approximately 7,400 amps, out of the 8,000 amps necessary to initiate the SONGS separation scheme. After the loss of the

[49] Larkspur generation is connected to the SDG&E 69 kV system south of Otay Mesa, and Kearny generation is connected to the SDG&E 69 kV system in northern San Diego.

Yucca 161/69 kV transformers, the YCA plant, and the Pilot Knob 161/92 kV transformers, the loading further increased to approximately 7,800 amps.

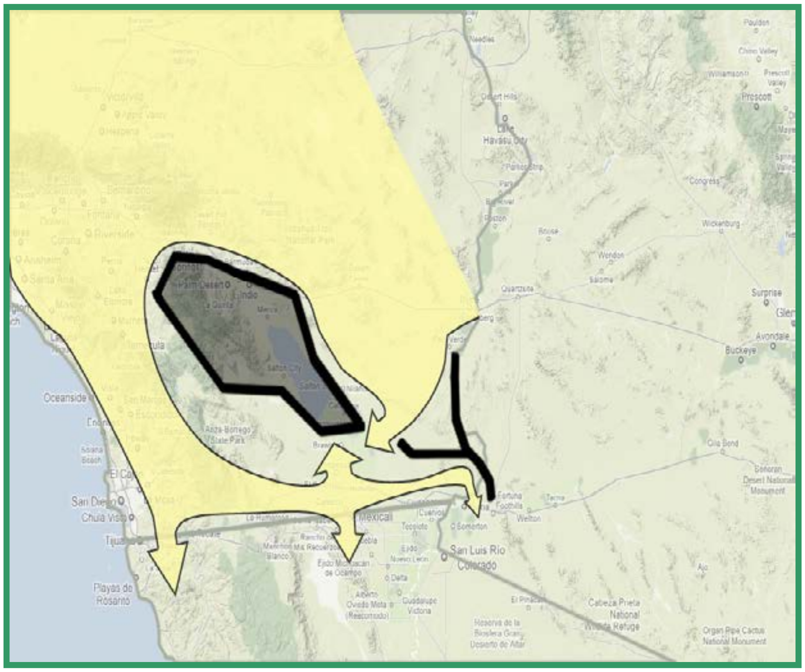
Time: 15:37:42



F. Phase 6: High-Speed Cascade, Operation of the SONGS Separation Scheme and Islanding of San Diego, IID, CFE, and Yuma

Phase 6 summary:

- Timing: 15:37:55 to 15:38:21.2
- IID's El Centro-Pilot Knob line tripped, forcing all of IID's southern 92 kV system to draw from SDG&E via the S Line
- S Line RAS operates, tripping generation at Imperial Valley and worsening the loading on Path 44
- S Line RAS trips S Line, isolating IID from SDG&E
- Path 44 exceeds trip point of 8,000 amps, to as high as 9,500 amps
- SONGS separation scheme operates and creates SDG&E/CFE/Yuma island

When the El Centro-Pilot Knob 161 kV line tripped at 15:37:55 (10 minutes after loss of H-NG), it isolated the southern IID 92 kV system onto a single transmission line from SDG&E: the S Line. Forcing all of the remaining load in IID to draw through the SDG&E system pushed the aggregate current on Path 44 to 8,400 amps, well above the trip point of 8,000 amps. If the aggregate current on Path 44 remained above 8,000 amps, the definite minimum time relay[50] would initiate the SONGS separation scheme to separate SDG&E from SCE at SONGS.

IID's El Centro-Pilot Knob 161 kV line open-ended at El Centro when a 161 kV breaker at El Centro tripped on Zone 3 relay protection[51] with a one second delay. The apparent impedance detected on the Zone 3 relay at El Centro was hovering near its trip zone immediately following the Pilot Knob 161/92 kV transformer trips (12 seconds earlier), but did not cross into the Zone 3 tripping region until this time.

By this time in the event, the South of SONGS lines were San Diego's only source of critical imported generation, and were also keeping IID and CFE's Baja California Control Area from going dark. If the aggregate current was brought below 8,000 amps, the blackout could have been avoided, but at this point no operator action could have occurred quickly enough to save the South of SONGS Path. Had there been formal operating procedures that recognized the need to promptly shed load as the aggregate current approached 8,000, and had operators been trained on the 8,000 amp set point, it is possible that operation of the SONGS separation scheme could have been averted by earlier control actions.

Milliseconds after the loss of IID's El Centro-Pilot Knob 161 kV line, at 15:37:55.890, NextEra's Buck Boulevard combustion turbine generator tripped due to operation of SCE's Blythe Energy RAS, dropping 128 MW of generation.[52] This was caused by a reduction of counter-flows on the Julian Hinds-Mirage 230 kV line that had been created by heavy flows from the Julian Hinds-Eagle Mountain 230 kV line feeding toward the WALC 161 kV system to support the heavy north to south 161 kV flows toward Pilot Knob. When the El Centro-Pilot Knob 161 kV line tripped, those counter-flows disappeared, initiating the RAS operation. The Buck Boulevard heat recovery unit ramped down by 82 MW over the next few minutes. The Buck Boulevard combined cycle plant was generating 409 MW (535 MW rating) at the time the combustion turbine tripped. Tripping the Buck Boulevard generator did not increase loading on Path 44, because it is not located south of Path 44.

---

[50] A definite minimum time relay can operate in one of two ways. When current reaches a certain value, the relay will operate with a *definite* time delay that reflects the relay's fastest operating time. Before the relay reaches that value, the time for the relay to operate is *inversely proportional to its observed current magnitude*. During the event, the relay operated while following the latter characteristic.

[51] *See* footnote 47, *supra*.

[52] The Blythe Energy RAS, among other functions, trips generation owned by NextEra to protect the Julian Hinds-Mirage 230 kV line from overloading with east to west flows for a potential loss of the Julian Hinds-Eagle Mountain 230 kV line. Buck Boulevard is connected to SCE's 230 kV system in the Blythe area.

Just three seconds after the loss of IID's El Centro-Pilot Knob 161 kV line, at 15:37.58.2, the S Line RAS at Imperial Valley Substation initiated the tripping of two combined cycle generators at Central La Rosita in Mexico. The S Line RAS currently protects El Centro's 161/92 kV transformer No. 2 by initially tripping a combination of CLR II generators when the flow on the S Line exceeds 269 MW flowing northward from SDG&E into IID. Two combustion turbines were loaded to 152 MW (193.5 MW rating), and 153 MW (193.5 MW rating), respectively, and the associated steam heat recovery unit (which also tripped following loss of the turbines) was loaded to 127 MW (159.3 rating), totaling 432 MW of generation.

Loss of the CLR II generation drove the South of SONGS flows from about 8,400 amps to about 9,500 amps, which remained above the 8,000 amp setting of the SONGS separation scheme. The inquiry's simulation showed that had the S Line tripped without the S Line RAS tripping the CLR II generation, the flow on Path 44 would have fallen below 8,000 amps to settle at an estimated 7,730 amps, and the SONGS separation scheme might not have operated.[53]

Approximately four seconds after the S Line RAS tripped the CLR II generators, at 15:38:02.4 the S Line RAS tripped the S Line itself due to flow above 289 MW toward IID from SDG&E. Tripping of this line created an IID island. IID reported that from 15:37:59 to 15:40:24, 507.85 MW of load tripped on its system, mostly in the southern 92 kV system.

The tripping of the S Line meant that IID was no longer pulling power from SDG&E and CFE through Path 44, so the aggregate Path 44 flows decreased from approximately 9,500 amps to approximately 8,700 amps, but were still above the 8,000 amps required to trigger the SONGS separation scheme.

At 15:38:21.2, not quite 11 minutes after H-NG tripped, the SONGS separation scheme operated, reconfiguring the SONGS 230 kV switchyard and isolating the SONGS generators onto the SCE system to the north. This reconfiguration effectively separated

---

[53] The inquiry's simulation showed that if the S Line RAS tripped only the S Line, IID's system would still have collapsed, but San Diego and the Yuma load pocket would likely have survived. Voltages would have remained acceptable, and the 230 kV system around SONGS may have experienced minor overloads. While this would have resulted in a large phase angle difference on H-NG, the fact that the SONGS separation scheme would not have operated would have allowed time for system operators to make the load and generation changes necessary to reduce the phase angle difference.

Had the S Line RAS not operated at all, or only operated to trip the CLR II generators, Path 44 flows would have settled above the 8,000 amp threshold and thus the SONGS separation scheme would still have operated.

all five South of SONGS 230 kV transmission lines from the SONGS units and the SCE system, and separated SDG&E from the rest of the Western Interconnection. Operation of the SONGS separation scheme created an island consisting of the SDG&E system, the remaining Yuma-area load connected through the 500 kV system from Miguel to North Gila, and CFE's Baja California Control Area.

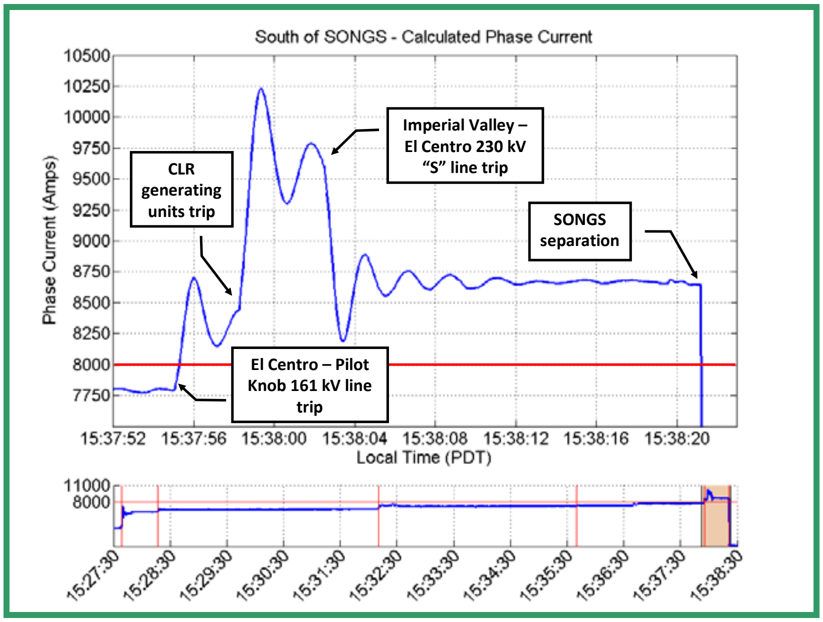
September 8, 2011, was the first time that the SONGS separation scheme had ever activated, and its effects on neighboring systems had not been studied. Although this sequence of events has focused on how the loss of elements combined over the 11 minutes to exceed the 8,000 amp SONGS separation scheme trigger, in real time, no entity was monitoring that limit or recognized the potential consequences of its operation.

WECC RC, responsible for the reliable operation of the BPS, and with having a wide area view of the BPS, did not have any alarm that would alert operators before operation of the separation scheme. Although WECC RC operators were monitoring the Path limit on Path 44, they were not watching the aggregate flows with respect to the SONGS separation scheme trigger. WECC RC operators noticed the five South of SONGS breakers open after the scheme had already operated.

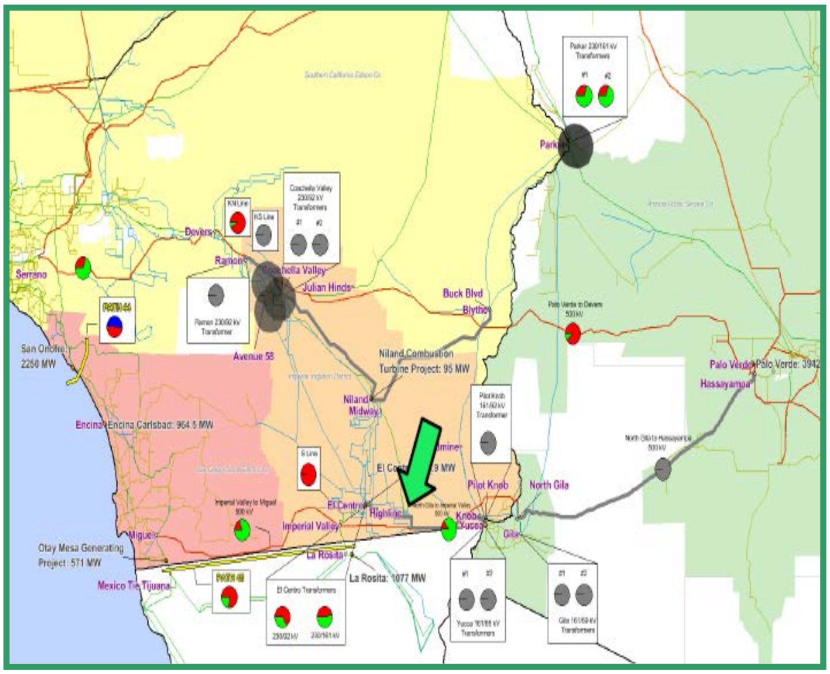
CAISO, the TOP for SDG&E and SCE, did not have any alarms specifically tied to the operation of the SONGS separation scheme either. CAISO only has alarms for when Path 44 exceeds its Path rating, but had no ability to monitor the SONGS separation scheme, set at 3,100 MW (8,000 amps). After the loss of H-NG, which caused Path 44 to exceed its Path rating, CAISO operators were primarily concerned with returning flows on Path 44 to below the Path rating of 2,500 MW, but believed they had 30 minutes to do so. Unlike Path ratings, the separation scheme would not allow CAISO operators 30 minutes to reduce flows on Path 44. CAISO did attempt to dispatch additional generation within SDG&E to reduce flows on Path 44. The other method to reduce flows would have been to manually shed load in SDG&E in time to prevent operation of the SONGS separation scheme. SDG&E estimates that it could have shed approximately 240 MW in between two and two-and-a-half minutes. However, SDG&E was never instructed to shed load and was unaware of the need to shed load.

Phase 6 Graphics

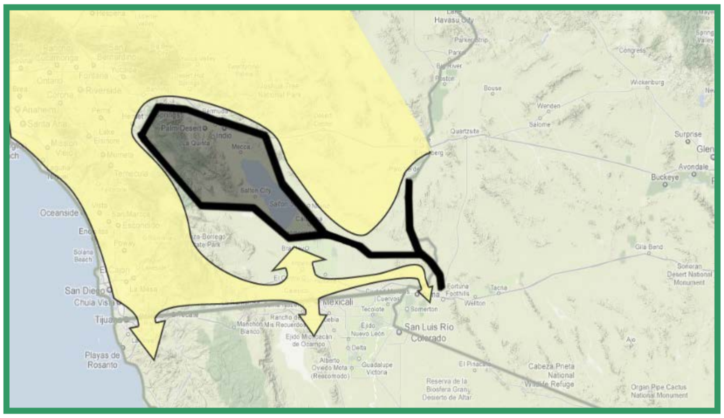
South of SONGS – Calculated Phase Current



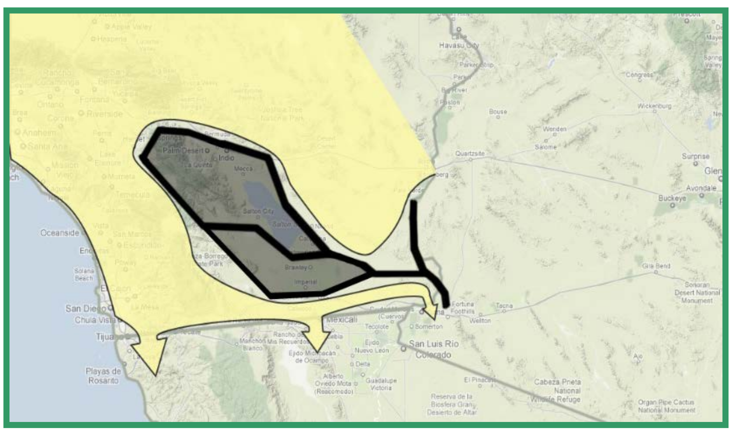
Time: 15:37:55 – The El Centro-Pilot Knob 161 kV line tripped. (230)



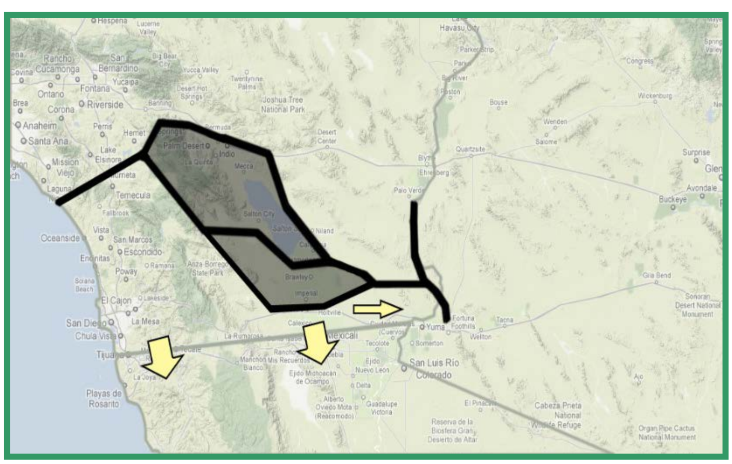
Time: 15:37:55.110



Time: 15:38:02.4



Time: 15:38:21.2



G. Phase 7: Collapse of the San Diego/CFE/Yuma Island

Phase 7 Summary:

- Timing: Just after 15:38:21.2 to 15:38:38
- Underfrequency Load Shedding (UFLS) was not able to prevent the SDG&E/CFE/Yuma island from collapsing
- SONGS nuclear units shut down even though they remained connected to the SCE side of the SONGS separation scheme

During phase 7 of the event the SDG&E/CFE/Yuma island broke into three separate islands, all of which collapsed due to an imbalance between generation and demand, resulting in severe underfrequency which tripped both loads and generation.

The SDG&E/CFE/Yuma island created by operation of the SONGS separation scheme had a significant imbalance between generation and load from the beginning. As a result, the frequency in the island rapidly declined. By less than a second after the SONGS separation scheme activated (15:38:22), the UFLS programs of SDG&E, APS, and CFE had all began activating within the island. *Figures* 10 and 11, below show the frequency within the island as it collapses. All steps of the UFLS systems activated and system frequency in the island briefly stalled at approximately 57.2 hertz (Hz). CFE's UFLS analysis showed 512 MW of load shed by 15:38:21.901.

However, the same analysis showed that three CFE generators, totaling 459 MW, tripped offline beginning at 15:38:21.905, partially negating CFE's UFLS actions. In addition, a number of smaller generators, totaling about 130 MW, tripped only 0.5 seconds later while CFE was still connected to SDG&E and while SDG&E's UFLS program was still working to shed load.[54] See *Figure* 11, below. The net effect of CFE's UFLS actions and generator trips—512 MW shed by UFLS and 590 MW of tripped generation—was that CFE's imports from SDG&E increased from approximately 440 MW to approximately 520 MW. This worsened CFE's system conditions and increased the stress on SDG&E before SDG&E's underfrequency separation protection systems opened the ties between CFE and SDG&E. SDG&E also had three generators with underfrequency protection that operated at 57.3 Hz, above the frequency at which the system leveled out. Due to these early generation losses, the frequency continued to decline below 57 Hz, which was the underfrequency setting for the majority of generators in the island. Thus, the island blacked out, shortly after separating into three sub-islands.

---

[54] The fact that several generators tripped during load shedding suggests that CFE may benefit from analyzing whether its UFLS program and generator underfrequency protection systems are coordinated.

Figure 10: Frequency, Voltage in the SDG&E/Yuma/CFE Island

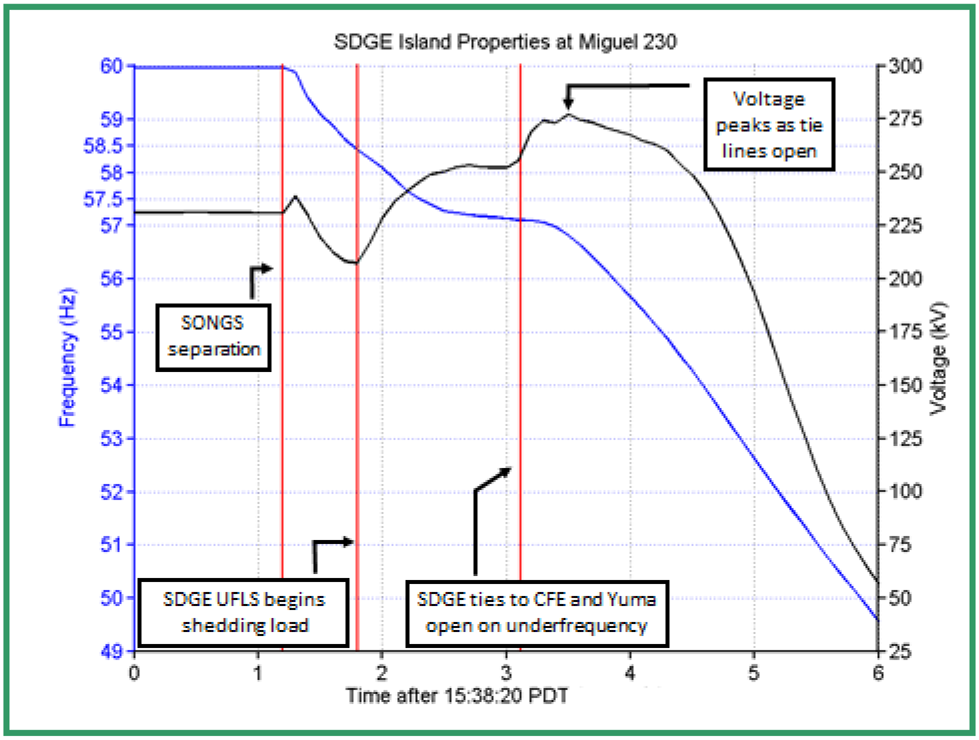


Figure 11: Frequency Performance in the SDG&E/Yuma/CFE Island

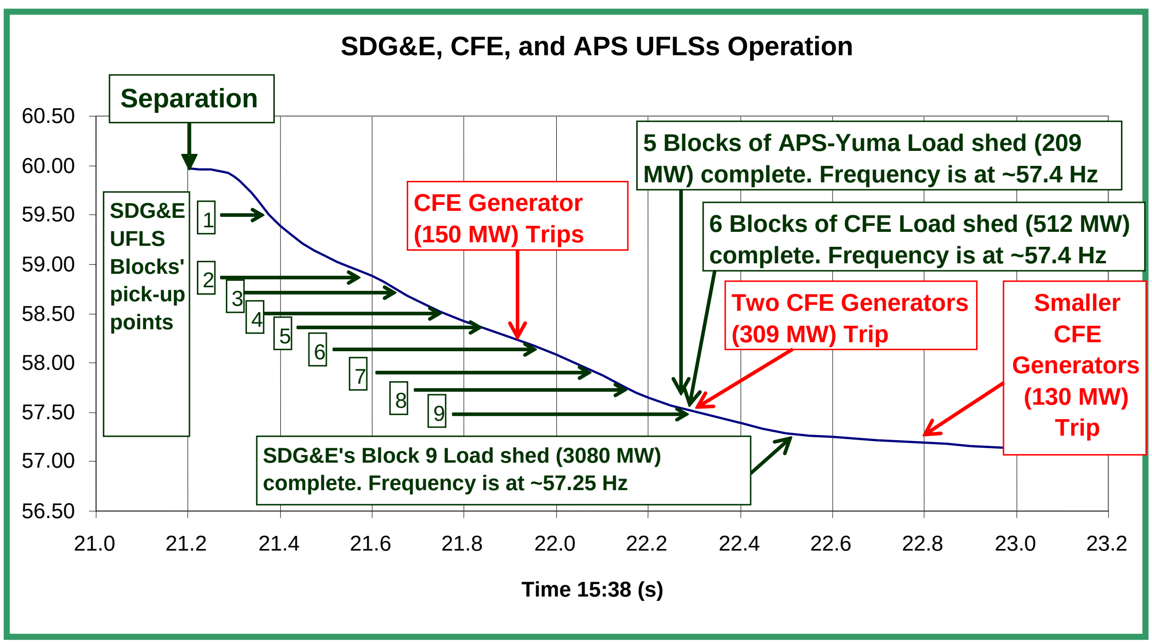

The CFE island separated from SDG&E after their only two remaining ties tripped in rapid succession. At 15:38:22.2, the Otay Mesa-Tijuana 230 kV transmission line open-ended at Tijuana in CFE's territory due to underfrequency protection.[55] Less than a second later, at 15:38:23.13, the Imperial Valley-La Rosita 230 kV transmission line open-ended at Imperial Valley in SDG&E's territory by underfrequency protection.[56] According to CFE, its UFLS program was not designed for the operation of a SDG&E/CFE/Yuma island, but for the operation of a "southern WECC island."

The Yuma island separated from SDG&E at 15:38:23.12, when the Imperial Valley-North Gila 500 kV transmission line tripped by underfrequency protection. APS's UFLS operated on 26 out of the 28 feeders in the Yuma area prior to the loss of the local Yucca steam generators that were on line. However, there was insufficient local generation to stabilize the load pocket in Yuma. At 15:38:38, the Yuma island internal units tripped on underfrequency protection.

At about the same time that it separated from CFE and APS's Yuma pocket, SDG&E lost four generating units, totaling 570 MW, due to the generators' underfrequency protection.[57]

Although the SONGS generators remained connected to the SCE side of the switchyard at SONGS, at about 15:38:27.5, or approximately six seconds after the SONGS separation scheme initiated, the SONGS turbines both experienced a brief acceleration in speed and tripped due to turbine control logic. At the same time, local system frequency at SONGS was observed to spike from 59.974 Hz to 61.203 Hz. After the initial impulse caused by the system separation, the frequency in the main body of the Western Interconnection peaked near 60.170 Hz. This can be seen on Figures 12 and 13, on the next page. The turbine trip initiated a reactor shutdown, and the units began coasting down. A little more than a second later, at 15:38:28.963, SONGS Unit 3 electrically disconnected from the system, and less than three seconds after the reactors shut down, at 15:38:30.209, SONGS Unit 2 electrically disconnected from the system.

---

[55] The Tijuana end opened instantaneously. Subsequently, the Otay Mesa end of the line in SDG&E's territory opened at 15:38:23.044 by underfrequency protection (with 1-second delay).

[56] The line's underfrequency setting was 57.9 Hz, with 1-second delay. The instantaneous underfrequency protection scheme at La Rosita in CFE's territory failed to operate due to a bad fuse connection.

[57] At 15:38:23.000, the Palomar Energy Center combustion turbines CT1 and CT2 tripped on underfrequency, followed by the heat recovery unit ST at 15:38:23.07 (all set to trip at 57.3 Hz with a 750 millisecond time delay). CT1 was loaded to 160 MW, CT2 was loaded to 165 MW, and ST was loaded to 195 MW at the time of the trips. It is believed that additional unit Goal Line LP, generating 50 MW, tripped around the same time due to a 58 Hz frequency with a 1-second time delay.

Loss of the 2,300 MW of SONGS' generation effectively reduced the loss of load for the main body of the Western Interconnection from a 3,400 MW loss to a net 1,100 MW load loss. This made the recovery from the resulting overfrequency event much easier. The SONGS generators did not lose offsite power because the SONGS switchyard was still connected to the SCE system.

H. System Restoration

None of the affected entities needed to implement black start plans because they all were able to access sources of power from their own or a neighbor's system that was still energized. The restoration process generally proceeded as expected, and some entities restored load more quickly than they had expected. The following charts indicate how long it took the affected entities to fully restore their lost load, generation, and transmission.

LOAD RESTORATION EFFORTS					
Entities	Demand Interrupted (MW)	Time Until Demand Fully Restored	Date Restored	100 % Demand Restored (hrs)	Number of Customers Affected
SDG&E	4,293	03:23	9/9/11	12	1.4 Million
CFE	2,205	01:37	9/9/11	10	1.1 Million
IID	929	21:40	9/8/11	6	146,000
APS	389	21:12	9/8/11	6	70,000
WALC	74	22:23	9/8/11	6.5	5[58]

58 The majority of WALC's lost load (64 MW) affected APS customers. SCE lost 117 fringe load customers who were served by the SDG&E system.

GENERATION RESTORATION EFFORTS				
Entities	Generation Lost (MW)	Time Generation Restored	Date Restored	Generation Restored (hrs)
SCE	2,428	06:33	9/12/11	87
SDG&E[59]	2,229	06:20	9/10/11	39
CFE	1,915	23:43	9/10/11	56
IID	333	20:42	9/8/11	5
APS	76	20:37	9/8/11	5

TRANSMISSION RESTORATION EFFORTS				
Entities	Final Transmission Restored (kV)	Time Transmission Restored	Date Restored	Transmission Restored (hrs)
IID	230 161	03:37 00:31	9/9/11 9/9/11	12 9
SDG&E	500 230	17:36 03:47	9/8/11 9/9/11	2 12
APS	500	16:51	9/8/11	1.5
WALC	161	17:09	9/8/11	1.5[60]
CFE	230 115	04:03 01:58	9/9/11 9/9/11	12.5 10

59 According to SDG&E, after restoring the SDG&E transmission systems, CAISO took over restoring SDG&E's generation.

60 This represents the time it took WALC to restore its 161/69 kV Gila transformers, however, none of WALC's transmission lines were lost in the outage.

WECC RC could have taken a more active role in coordinating the restoration efforts. WECC RC has the largest area of visibility and more advanced real-time study tools than the TOPs. During a multi-system restoration, issues are likely to arise between neighboring BAs and TOPs that may require either a neutral decision maker, or rapid technical analysis of unplanned system conditions. WECC RC is uniquely situated to provide such assistance. WECC RC should clarify its role, and the real-time information it can provide, in emergency situations like a multi-system restoration. WECC RC should also specifically address the issue of coordination among other functional entities (like BAs and TOPs) in its operating area, outlining the areas of responsibility during system restoration and other emergencies.

The inquiry reviewed recordings and other data about restoration which disclosed the following incidents that could have benefitted from better WECC RC coordination and assistance in real time:

- A 30-minute debate occurred between SCE, which was attempting to provide cranking power to SDG&E to restore SDG&E's system, and the SONGS operators, about the conditions necessary for resetting the SONGS separation scheme lockout relay.
- Recordings showed a lack of clarity among WECC RC, CAISO, and SDG&E about responsibilities for restoration efforts. Among other things, this resulted in a SONGS operator making a unilateral decision to open a circuit breaker on the line responsible for restoring power to SDG&E's system, leaving the line in a less reliable configuration (connected to a single bus).

IV. Causes, Findings, and Recommendations

A. Planning

Next-Day Planning

- **Background**

TOPs are required to perform next-day studies to identify and plan for potential limitations on their system in the day-ahead timeframe, and to coordinate these studies with their neighboring TOPs.[61] These studies provide a proactive mechanism to ensure that the system can be operated reliably and allow time to develop effective operating solutions.[62] These solutions include, among other things, effective control actions needed to return the system to a secure state in anticipated normal and contingency system conditions. The development of these plans in the day-ahead timeframe is critical because it would be nearly impossible, due to the complexity of the BPS, for control room operators to return the system to a secure operating state under stressed conditions without effective action plans developed in advance. The adequacy of next-day studies depends on how extensively and accurately facilities and next-day system conditions are incorporated into the models used for the studies. This includes consideration of a reasonably accurate, current, and complete list of external contingencies that could impact a TOP's system as well as internal contingencies that could impact external SOLs. Consistency of study inputs among all TOPs and BAs is also critical for reliable operation.

The inquiry found that the affected TOPs' and BAs' procedures for conducting next-day studies and models used in these studies vary considerably. As explained more fully below, APS does not conduct next-day studies, relying, instead, on two sets of studies, conducted on a seasonal and annual basis, that consider a list of possible, predetermined contingency scenarios and provide plans to mitigate the contingencies if violated. Meanwhile, IID has a policy of conducting next-day studies each day, but between April and October of 2011, it failed to perform the required studies on a daily basis. All other affected TOPs conduct next-day studies, but they use models that do not adequately reflect next-day operations of facilities in networks external to them. These

[61] *See* NERC Reliability Standard TOP-002-2b R11.

[62] *See, e.g.*, NERC Reliability Standard TOP-002-2b ("Current operations plans and procedures are essential to be prepared for reliable operations, including response for unplanned events.").

TOPs' next-day studies also do not consider a full list of internal and external contingencies that could impose limitations on their daily operations or external operations. Moreover, most of these TOPs' next-day studies do not consider the impact of sub-100 kV facilities on BPS reliability, such as the impact of IID's CV transformers.

WECC RC is the highest level of authority responsible for reliable operation of the BPS in the Western Interconnection, with the authority to prevent or mitigate emergency operating conditions in the next-day and real-time timeframes. As such, WECC RC also conducts next-day studies for the entire Western Interconnection and builds its model from the previous day's peak State Estimator case, which includes all facilities operated at 100 kV and above and some sub-100 kV facilities. WECC RC then incorporates forecast information, which typically includes transmission outages as provided by TOPs, generation outages or derates of 50 MW or greater as provided by TOPs, as well as load forecasts, expected net interchange, and unit commitment forecast data from BAs. While WECC RC has a more extensive representation of facilities throughout the WECC footprint in its model than any individual TOP, it does not necessarily monitor or alarm for certain lower voltage facilities and facilities deemed non-BES that can impact BPS reliability. Moreover, because some of the forecasted information can change between the time the TOPs and BAs provide it to WECC RC and the time WECC RC runs its next-day studies, WECC RC's next-day studies might not accurately reflect next-day operations.

The September 8th event exposed four weaknesses with the foregoing procedures for conducting next-day studies in WECC's region. These weaknesses are detailed in the following four findings. A common theme prevails in all four findings: the affected entities do not accurately account for external next-day operating conditions or potential external contingencies that could impact their systems.

Finding 1 Failure to Conduct and Share Next-Day Studies:

- **Not all of the affected TOPs conduct next-day studies or share them with their neighbors and WECC RC. As a result of failing to exchange studies, on September 8, 2011 TOPs were not alerted to contingencies on neighboring systems that could impact their internal system and the need to plan for such contingencies.**

Recommendation 1:

- **All TOPs should conduct next-day studies and share the results with neighboring TOPs and the RC (before the next day) to ensure that all contingencies that could impact the BPS are studied.**

Failure to Conduct Next-Day Studies

APS does not conduct next-day studies. Instead, it relies on two sets of studies, conducted on a seasonal and annual basis, for its daily operations. First, APS uses its summer and winter seasonal studies for the non-WECC Rated Paths within its transmission system. APS performs these studies on a model that it builds from the WECC heavy summer base case. In a coordinated effort with other entities in Arizona, it updates this WECC base case with anticipated loads and resources from the state. APS then adds a detailed representation of the entire state's network, including its own subtransmission system down to the 12 kV distribution system, to finalize the summer model. To create its winter model, APS modifies the summer model with winter peak conditions throughout Arizona.

Once these summer and winter models are complete, APS studies a set of predetermined contingencies, and relies on the results to determine the response of its transmission system to single and multiple contingencies during peak load conditions with planned outages modeled. The studies' list of contingencies is based on past studies, operating experience, and engineering judgment. The studies also establish mitigating measures for contingencies that do not meet loading or voltage guidelines.

Second, APS relies on a single manual, developed annually, as a guide for its daily operations on four Rated Paths within its system. This manual is the result of studies of possible, predetermined contingencies on Rated Paths. The results and operational instructions in this manual are based on seasonal models that APS develops in coordination with four WECC regional study groups, led by CAISO. CAISO first sends a base case to each study group to update with topology changes for the upcoming season. Individual members of each study group also update the model with details from their systems. CAISO then incorporates all of the updates and stresses key Paths in California before sending the model back to the study groups. APS uses this model as a starting point to study the four Rated Paths in its system. APS analyzes the resulting peak-load model using a predetermined set of single and double contingency events that are focused primarily on high-voltage transmission outages to determine required actions to secure the system for the next most critical N-1 event.[63] The manual directs APS to rerate relevant Path(s) and identifies necessary mitigating measures as long as the contingency (or multiple contingency) scenario is included in the manual. The manual, however, may not include a particular contingency (or multiple contingency)

[63] APS's manual covers only 500 kV and 345 kV facilities, and nothing lower.

scenario, or may not accurately reflect the internal and external system topology for the day in question, resulting in the potential for unforeseen circumstances.

Thus, APS uses seasonal studies for non-Rated Paths and the manual for Rated Paths as tools in the day-ahead timeframe, without any additional analysis to validate that the tools remain valid for the next day's specific configuration and operation, such as transmission or generation outages external to APS's footprint that were not anticipated at the time the base seasonal study was performed. APS maintains that these tools are sufficient for day-ahead purposes because they include the most severe contingencies identified in its system. This viewpoint overlooks the purpose of next-day studies—to plan for next-day operations *in light of conditions that change daily*. By relying on tools based on studies conducted on a seasonal and annual basis, APS cannot account for all plausible daily scenarios. For typical days that fall within the boundaries of the underlying studies and analysis, APS's tools may be viable. For atypical days where conditions fall outside the studied boundaries, however, this approach may not be adequate. For example, September 8, 2011, was an atypical day not contemplated by APS's manual, as the manual did not account for various generation outages in effect for maintenance.

Between April and October 2011, IID also did not consistently perform adequate next-day analyses for each day. Although IID had a policy of conducting separate next-day analyses for each new day, it failed to consistently perform the required analyses. Specifically, IID produced a document each new day showing various changes in weather, load and generation forecasts, planned facility outages, potential contingency violations, or mitigation measures for identified contingencies, but did not always perform the underlying power flow studies for each day between April and October 2011. On average, between April 2011 and October 2011 IID actually performed a study no more than two times per week. For the other days, IID simply referenced past studies. For example, it appears that IID did not perform a separate, updated study for September 8, 2011, because the powerflow study case provided for this day does not match the contingency results included in the daily operations guide for the day. In other words, it appears that for September 8, 2011, IID simply changed the forecasted data without actually performing the next-day study. Instead, IID referenced a previous study. The referenced study, however, was not valid because it did not match the load and generation dispatch data for the day, and there were differences in projected overloads reported as potential contingencies. IID's next-day studies were purportedly reviewed by IID for accuracy, but these discrepancies were not identified. IID discovered this issue during the course of the inquiry and is in the process of implementing corrective actions to ensure accurate next-day analyses are completed in the future.

Finally, the inquiry heard on more than one occasion from TOPs, including APS, that WECC RC was responsible for conducting next-day studies or that WECC RC should conduct next-day studies that TOPs are currently responsible for conducting. WECC RC's next-day studies for the entire Interconnection, however, are not intended to substitute for the TOPs' next-day studies of their own systems.

Failure to Effectively Share and Coordinate Next-Day Studies

In addition to finding that not all entities conduct next-day studies, the inquiry found problems with sharing and coordination among the affected TOPs that do conduct such studies. The affected TOPs do not consistently share their studies with neighboring TOPs, BAs, and the RC. TOPs generally provide studies to WECC RC only if the RC identifies an issue in its study and specifically asks to review a TOP's study. In addition, WECC RC's method of sharing its next-day studies with other entities is not effective. Specifically, WECC RC's practice is to share the results of its next-day studies when conditions warrant, or when it receives a request for a study result.[64] WECC RC posts on a secure Internet portal a list of limitations or SOLs identified by its next-day studies for individual TOPs and BAs to view, but it is up to TOPs and BAs to access this list. Also, this list contains only issues that WECC RC deems significant and does not include basic, next-day operating conditions, such as scheduled outages.

One example of the adverse consequences of these sharing and coordination issues relates to the 600-plus MW of TDM generation that was offline for maintenance on September 8th. The TDM generation outage was included in WECC RC's and CAISO's next-day studies, and posted on CAISO's website, but not incorporated into other entities' next-day models and studies.[65] WECC RC receives outage information from TOPs and BAs through its Coordinated Outage System (COS). While TOPs and BAs submit their own information into COS, they cannot access information submitted by others. IID could have benefitted from knowledge of the TDM outages. The TDM units radially connect to the Imperial Valley substation, jointly owned by IID and SDG&E. If the TDM units had been online, they could have mitigated northern IID overloads on the

---

[64] *See* WECC Reliability Coordination, Operations Planning, Version 3.0, June 22, 2011, at 6, *available at* http://www.wecc.biz/awareness/Reliability/WECC RC Operating Procedures/WECC RC Operations Planning.pdf.

[65] CAISO knew about the outages because the TDM units participate in the CAISO market. CAISO posts daily outage unit status reports on its public website that provide the best available data at the date and time of the report, for generation units that participate in CAISO's market. These outages are posted at http://www.caiso.com/market/Pages/OutageManagement/UnitStatus.aspx. In CAISO's archives, the TDM units are shown on outage on September 7 and 8, at a minimum. Dispatch details, however, are not included. WECC RC receives CAISO's outage unit status reports daily by email and was aware of the outages. However, IID and APS did not know about the TDM outages.

CV and Ramon transformers that resulted when H-NG tripped. If IID had learned about these outages from WECC RC or CAISO, it could have incorporated the outages in the day-ahead timeframe and dispatched additional generation, or taken other control actions, to compensate for the overloads on its system caused by having these generators offline and the H-NG tripping.

The September 8th event illustrates that conducting next-day studies and sharing the results of such studies are critical to allow TOPs to identify and plan for potential contingencies.

Finding 2 **Lack of Updated External Networks in Next-Day Study Models:**

- **When conducting next-day studies, some affected TOPs use models for external networks that are not updated to reflect next-day operating conditions external to their systems, such as generation schedules and transmission outages. As a result, these TOPs' next-day studies do not adequately predict the impact of external contingencies on their systems or internal contingencies on external systems.**

Recommendation 2:

- **TOPs and BAs should ensure that their next-day studies are updated to reflect next-day operating conditions external to their systems, such as generation and transmission outages and scheduled interchanges, which can significantly impact the operation of their systems. TOPs and BAs should take the necessary steps, such as executing nondisclosure agreements, to allow the free exchange of next-day operations data between operating entities. Also, RCs should review the procedures in the region for coordinating next-day studies, ensure adequate data exchange among BAs and TOPs, and facilitate the next-day studies of BAs and TOPs.**

As a starting point for their next-day studies, the affected TOPs use models from either a TOP's seasonal base case or the previous day's EMS model, if available. The seasonal base case represents next-day operating conditions internal to the TOPs' systems, but leaves external networks exactly as they were represented in the WECC seasonal base case. The affected TOPs' EMS models sometimes include only one or two buses outside each TOP's internal footprint. Thus, neither type of day-ahead model contains actual day-ahead forecasts of system conditions external to each TOP's system. For example, leading into September 8th, the affected TOPs had limited knowledge of the current status of transmission facilities, expected generation output, and load predictions outside their footprints. Consequently, their next-day studies could not adequately predict the impact of external contingencies on their systems or of internal contingencies on external systems.

IID's next-day study for September 8th illustrates the adverse effects of not accounting for external next-day planned operations. IID used the WECC heavy summer seasonal base case to model external conditions for its next-day study for September 8th. This base case reflects that most external generation is online to meet summer peak loads. A heavy summer base case does not accurately represent a shoulder season day like September 8th. By September, both generation and transmission maintenance had started.

For example, on September 8th TDM generator units in Mexico, totaling more than 600 MW, were offline for maintenance. These units are external to IID and radially connect to IID's jointly owned Imperial Valley substation. When online, this generation can help to mitigate overloads on the CV and Ramon transformers in IID's system. Because IID relied on a heavy summer seasonal model for external networks and did not incorporate any updates about the TDM generation, its next-day study did not reflect the maintenance outage of these units. With the TDM generation incorrectly represented as being online, IID's next-day study did not correctly identify how much the loss of H-NG would overload IID's transformers in its 92 kV system. In fact, IID's next-day study for September 8, 2011, did not show that the loss of H-NG would overload the CV transformers to their trip point.[66] If IID had learned about the TDM outages (whether from CAISO's website or BY some other method) and incorporated the information into its model, it could have dispatched additional generation, adjusted load, or taken other control actions before the loss of H-NG to mitigate such overloading.

As mentioned above, WECC RC receives next-day data from the entities through interfaces such as the COS. WECC RC is well-situated to facilitate data-sharing among the 37 BAs and 53 TOPs in the WECC footprint. Given the large number of BAs and TOPs in the WECC region, some of which are relatively small in size and resources, central coordination and facilitation may be necessary to ensure that all BAs and TOPs accurately reflect next-day operating conditions external to their system.[67] WECC RC has been working to facilitate data sharing by drafting and circulating a universal

---

[66] The heavy summer base case has more than 1,000 MW more generation in the affected area than was available on September 8, 2011. In addition to not representing the offline generation, IID's study, by relying on the heavy summer base case, did not accurately reflect the flow on H-NG. The heavy summer base case shows flow on H-NG as 1,118 MW, while actual flow on H-NG at the time of the trip was 1,391 MW.

[67] Under current WECC RC procedures, the RC only shares the results of its operational planning analyses if the results indicate the need for specific operational actions to prevent or mitigate an instance of exceeding an operating limit. WECC Reliability Coordination, Operations Planning, Version 3.0, June 22, 2011, at 6, *available at* http://www.wecc.biz/awareness/Reliability/WECC RC Operating Procedures/WECC RC Operations Planning.pdf.

nondisclosure agreement. As this report was being finalized, less than 30 of the approximately 100 discrete entities within WECC had signed the agreement.[68]

Finding 3 Sub-100 kV Facilities Not Adequately Considered in Next-Day Studies:

- **In conducting next-day studies, some affected TOPs focus primarily on the TOPs' internal SOLs and the need to stay within established Rated Path limits, without adequate consideration of some lower voltage facilities. As a result, these TOPs risk overlooking facilities that may become overloaded and impact the reliability of the BPS. Similarly, the RC does not study sub-100 kV facilities that impact BPS reliability unless it has specifically been alerted to issues with such facilities by individual TOPs or the RC has otherwise identified a particular sub-100 kV facility as affecting the BPS.**

Recommendation 3:

- **TOPs and RCs should ensure that their next-day studies include all internal and external facilities (including those below 100 kV) that can impact BPS reliability.**

The September 8th event showed that some sub-100 kV facilities can have significant impacts on BPS reliability, such as causing instability or cascading outages. Yet, it appears that these facilities are not adequately considered in the day-ahead timeframe. For example, IID's 92 kV network runs parallel to two major transmission Paths: (1) Path 44, which connects to the SWPL via the Palo Verde-Devers 500 kV line (part of Path 49) and runs to the north of IID; and (2) the SWPL, which runs to the south of IID. Given the parallel nature of its system, IID's 92 kV system is forced to carry a significant portion of any east-west power flows whenever segments of Path 44 or the SWPL are out of service.

Because none of the affected TOPs, besides IID, considered IID's 92 kV network in their next-day studies, they were not aware how their internal contingencies could affect IID's 92 kV network, or how an overload on IID's 92 kV network could affect their systems. For example, APS does not routinely study IID's lower voltage facilities, including the CV and Ramon transformers, in the day-ahead timeframe. APS uses seasonal studies and its operations manual as its tools in the day-ahead timeframe. While the model used for the seasonal studies physically has IID's 92 kV network represented, neither the model nor the operations manual are used to consider the next day's specific configuration and operation, such as transmission or generation outages external to APS's footprint that were not anticipated at the time the seasonal study and

[68] The agreement does address market concerns by requiring entities who participate in data-sharing to respect the separation of market and operations functions.

manual were updated. As a result, APS was not able to predict what occurred on IID's system—increased flows and overloading on its 92 and 161 kV transformers and transmission lines—when H-NG tripped offline. Similarly, affected TOPs other than IID do not consider in their day-ahead planning how the loss of the CV and Ramon transformers, leading to the S Line RAS operation, could adversely affect their internal systems. Accordingly, TOPs should revise their next-day study practices to account for all facilities, including those operated below 100 kV, that impact BPS reliability.

WECC RC also did not adequately consider sub-100 kV facilities not identified as BES that can have significant impacts on BPS reliability. While WECC RC does model IID's CV transformers in its next-day studies, prior to September 8, 2011, it did not "flag" them in its studies for active monitoring.[69] This means that WECC RC had data showing that the transformers would overload under certain conditions, but the overloads were not identified by alarms to be seen by RC operators. WECC RC did not actively monitor the CV transformers in its next-day studies because they are below 100 kV and IID had not alerted WECC RC to any issues that would warrant monitoring of the transformers. Given the CV transformers' impact on BPS reliability, WECC RC should actively monitor these transformers.[70]

Finding 4 Flawed Process for Estimating Scheduled Interchanges:

- WECC RC's process for estimating scheduled interchanges is not adequate to ensure that such values are accurately reflected in its next-day studies. As a result, its next-day studies may not accurately predict actual power flows and contingency overloads.

Recommendation 4:

- **WECC RC should improve its process for predicting interchanges in the day-ahead timeframe.**

Interchanges are energy transfers that cross BA Areas. Interchanges can affect flows across transmission systems, so forecasting accurate interchanges is important in the day-ahead timeframe to plan for potential overloading. WECC RC's process for estimating scheduled interchanges is not adequate to ensure that the scheduled interchanges incorporated into its next-day studies are accurate. Under this process, by 10:00 AM each day BAs provide WECC RC with all interchanges they have approved for

---

[69] To aid in effectively and efficiently processing and analyzing reliability data for the entire Western Interconnection, WECC RC has the option of flagging a subset of facilities for active monitoring in its studies. It has since updated this feature to flag the CV transformers for monitoring.

[70] WECC RC has implemented new procedures since September 8, 2011, to monitor RTCA results for the CV transformers.

the next day. The BAs typically submit this information once per day without any subsequent updates. WECC RC then validates these scheduled interchanges by comparing the values with what the BAs provided the prior day and with what WECC RC's state estimator observed in the prior days and weeks.

The accuracy of interchange data in WECC RC's next-day studies could be improved by allowing for updates closer to real time. BAs' interchange data are likely to change after their 10:00 AM submittal to WECC RC. Some BAs have automated systems, which send updates of interchange data to WECC RC. Most BAs submit the data manually, only once at 10:00 AM. Inclusion of a process or requirement for BAs to update their scheduled interchanges after their 10:00 AM submission would increase the likelihood of accurate interchange data.

The accuracy of interchange data affected WECC RC's next-day study for September 8, 2011. Specifically, the scheduled interchanges reflected in WECC RC's next-day study for September 8, 2011, were not sufficiently accurate to predict that IID's CV 230/92 kV transformers would overload to their trip point upon the loss of H-NG. After the event, WECC RC ran its next-day study using *actual* interchanges, and found that the CV transformers would overload beyond their tripping threshold upon the loss of H-NG. If WECC RC had used more accurate net interchange data and flagged the CV transformers for monitoring, it could have learned of the issues with these transformers and alerted IID or issued directives for control actions to mitigate the situation, such as increasing generation or shedding load.

Seasonal Planning

- ### Background

Following a set of disturbances in the Western Interconnection during the summer of 1996, WECC established a new seasonal planning structure designed to avert system-wide disturbances while maximizing the commercial availability of transmission capacity. This new structure involved the creation of the Operating Transfer Capability Policy Committee (OTCPC). The purpose of the OTCPC was to provide coordinated standard development and determination of seasonal Operating Transfer Capabilities (OTCs), or Operating Transfer Limits,[71] within the Western Interconnection.[72]

---

[71] OTCs are now known as SOLs.

[72] The OTCPC itself was abolished and replaced with a new structure in June 2011; however, planning for the seasonal period in which the blackout occurred was performed under the OTCPC structure, so the inquiry's analysis focused on the OTCPC structure.

Among other things, the OTCPC was designed to be responsible for determining which transmission Paths should be studied, facilitating OTC dispute resolution, ensuring that seasonal studies maintain consistent standards and methodologies, and approving seasonal studies of OTC limits. To that end, the OTCPC was charged with reviewing and approving study plans and technical simulation results; developing policies and procedures addressing seasonal OTCs; establishing working groups such as subregional study groups and the Operating Procedures Review Group; addressing OTC seams issues between subregions; and providing technical guidance.

The seasonal study plans that are reviewed and approved by the OTCPC were created by a set of four subregional study groups (sometimes referred to as SRSGs or simply subregions). There were four groups: (1) the California/Mexico Operations Study Subcommittee (OSS); (2) the Northwest Operational Planning Study Group (NOPSG); (3) the Rocky Mountain Subregional Study Group (RMSG); and (4) the Southwest Area Study Group (SASG). The affected entities were members of two of these groups: the OSS (CAISO, SDG&E, SCE, CFE, and IID) and the SASG (APS, WALC).

On an annual basis, each subregional study group reviewed the Paths in its subregion to determine which Paths should be studied and the system conditions under which they should be studied. Then, seasonally, the four subregional study group chairs submitted their recommendations of which Paths to study to the OTCPC for review and approval. Following OTCPC's approval, the studies were performed in accordance with the OTC study process. This process began with establishment of an initial "base case" by WECC staff, with input from representatives of each subregional group. The "base case" is a computer model of projected or starting power system conditions for a specific point in time. For the 2010-2011 planning year, five base cases were used.[73] Once the comments from the four subregional representatives were incorporated, the final cases were made available via WECC's web site for adjustment and modification by subregional members in order to forecast expected seasonal conditions on the system. The subregional members performed their own seasonal studies, and then met to discuss the results. A subregional seasonal planning case was produced on this basis, but no further studies were performed. Subregional seasonal cases were shared among the four subregions via liaisons from the other subregions. No comprehensive WECC-wide Path rating study was prepared on the basis of the four subregional studies.

[73] These included low summer load, high summer load, low winter load, high winter load, and high spring load.

In addition to, and apart from, the seasonal planning studies just described, TOPs also conduct their own seasonal studies focusing on their own internal networks. These internal studies follow a different process from the seasonal Path rating studies, though both begin with the WECC base case. Internal seasonal studies, however, are not aggregated or reviewed at the subregional level. Instead, TOPs generally replace the information from the WECC base case with more accurate and granular detail for their own areas only. Once updated, the TOPs perform contingency analyses for their own internal purposes. They then share with their neighbors the results of these operational studies, which typically contain only the default data from the WECC base case for everything outside of their own areas.

The inquiry identified a number of issues relating to both types of seasonal planning by the affected entities. These issues impaired the accuracy and effectiveness of the seasonal studies by excluding, in various ways, pertinent issues and information that should have been taken into consideration.

Finding 5 Lack of Coordination in Seasonal Planning Process:

- **The seasonal planning process in the WECC region lacks effective coordination. Specifically, the four WECC subregions do not adequately integrate and coordinate studies across the subregions, and no single entity is responsible for ensuring a thorough seasonal planning process. Instead of conducting a full contingency analysis based on all of the subregions' studies, the subregions rely on experience and engineering judgment in choosing which contingencies to discuss. As a result, individual TOPs may not identify contingencies in one subregion that may affect TOPs in the same or another subregion.**

Recommendation 5:

- **WECC RE should ensure better integration and coordination of the various subregions' seasonal studies for the entire WECC system. To ensure a thorough seasonal planning process, at a minimum, WECC RE should require a full contingency analysis of the entire WECC system, using one integrated seasonal study, and should identify and eliminate gaps between subregional studies. Individual TOPs should also conduct a full contingency analysis to identify contingencies outside their own systems that can impact the reliability of the BPS within their system and should share their seasonal studies with TOPs shown to affect or be affected by their contingencies.**

No comprehensive WECC-wide seasonal studies are performed. With respect to seasonal Path rating studies, a representative or leader from each subregion adapts the WECC base case on the basis of input from subregional members, and then makes these revised cases available to the other subregional members for review, comment, and approval. The subregional leader then conducts the seasonal studies concentrating only on the rated Paths in the subregion. The results of the seasonal Path rating studies are shared and discussed first among the subregion's members, and then with the other subregions, but neither WECC RE nor the OTCPC performs or mandates any further seasonal studies, and no new WECC-wide seasonal study is performed to reflect the input of all of the subregions. Instead, representatives of the subregional groups gather informally to discuss the results of their seasonal studies and rely on experience and engineering judgment to identify and resolve any issues.

The events of September 8, 2011, illustrate that this process is not adequate: the tripping of one line in a rated Path—H-NG, which is part of Path 49—ultimately led to the tripping of other lines in other rated Paths, including Paths 44 and 45. Focusing exclusively on Path ratings—and solely on a subregional basis—ignores network facilities that can impact rated Paths (and vice-versa) and does not account for the interrelationships of Paths and other facilities across WECC's subregions.

With respect to the internal seasonal studies, there is even less coordination. TOPs generally perform internal seasonal studies using models that include detailed data for their own system, but default to WECC base case data, which may not be sufficiently detailed or updated, for everything else. TOPs perform contingency analysis for their own internal areas using this model. No study is done to identify the impact of external contingencies on the TOP's system, or the impact of the TOP's internal contingencies on the SOLs of other TOPs. TOPs provide the results of their internal seasonal studies to neighboring TOPs for informational purposes, after which those TOPs may or may not provide comments.

In all, this situation indicates that the TOPs' internal seasonal planning studies are too heavily reliant upon the assumptions underlying and reflected in a single WECC base case, and do not consider and study impacts of variations from that base case.

The September 8th event demonstrated one example where better integration of seasonal studies across two subregions is needed. When H-NG (part of Path 49) tripped, approximately 12% of the flow from that line, which is located in the SASG subregion, was transferred across IID's 230/92kV transformers, via the IID 92kV local network to the southern IID 161 kV network, which are all in the OSS subregion. This additional flow on IID's CV transformers ultimately resulted in cascading outages and impacted Paths 44 and 45. The affected entities were unaware of this potential inter-Path impact, because the SASG and OSS studies had not been jointly considered. Moreover, since the subregional studies concentrate only on Path ratings, this flow transfer was not apparent. If the seasonal studies of SASG and OSS had been better coordinated and more rigorously analyzed, the potential for the loss of H-NG to overload IID's 92 kV network could have been identified and mitigation plans developed.

Finding 6 **External and Lower-Voltage Facilities Not Adequately Considered in Seasonal Planning Process:**

- **Seasonal planning studies do not adequately consider all facilities that may affect BPS reliability, including external facilities and lower-voltage facilities.**

Recommendation 6:

- **TOPs should expand the focus of their seasonal planning to include external facilities and internal and external sub-100 kV facilities that impact BPS reliability.**

As noted above, TOPs performing subregional Path rating studies do not sufficiently account for the impact of facilities external to their subregion, or facilities within their subregion that are not part of a rated Path. Moreover, no WECC-wide Path rating study is performed to harmonize and analyze the impact of one subregion on the rest of the subregions.

The problem with this approach is illustrated in the example cited above: The tripping of a part of one rated Path, H-NG, which is part of Path 49, led to the tripping of portions of other rated Paths. The mechanism whereby these other trips were triggered was the transfer of flow across low-voltage (below 100 kV) facilities that were located in a different subregion. Under the approach to Path rating studies in place at the time, it would have been impossible for WECC RE or TOPs to anticipate and study this possibility, because it occurred across subregions, indirectly, via lower-voltage facilities. Even if seasonal Path rating studies had been performed across subregions, these studies would not have anticipated this possibility, unless they also took into account lower-voltage facilities, which they presently do not.

The internal seasonal planning studies of the various TOPs are subject to similar omissions, although these studies encompass more than just the rated Paths and contain more detail than the Path rating studies. The practices of individual TOPs differ, but none contains sufficient detail and accuracy with respect to facilities outside their own footprints, as well as lower-voltage facilities. IID, for example, has explained that it "does not identify or study components outside of the IID territory below 100 kV for impacts on the BPS reliability in its territory," nor does it "identify or study components inside of the IID territory below 100 kV for impacts on the BPS reliability outside of its territory."

Similarly, while CAISO studies in its seasonal planning process "all of the transmission components that it operates, some of which are below 100 kV," it has also acknowledged that it "does not have the necessary information to accurately study transmission components below 100 kV outside of its territory to determine if they have an impact on the BPS reliability in [CAISO's] service territory."

The events of September 8, 2011, demonstrate that sub-100 kV facilities in parallel with BPS systems can have a significant effect on BPS reliability. The loss of H-NG caused the overloading and tripping of both 230/92 kV transformers at CV, which in turn caused another sub-100 kV transformer to trip at Ramon, which led to the cascading outages discussed in detail above. This possibility was not studied as part of the seasonal studies by any of the TOPs, other than IID, because the CV transformers' secondary windings are below 100 kV. The seasonal studies conducted by affected TOPs, other than IID, did not study the impact of the CV transformers. If the CV transformer contingency overloads had been identified as limiting elements in the seasonal plans, the cascading outages might have been avoided or lessened by having pre-contingency mitigation in place, such as increasing generation on IID's 92 kV system.

Finding 7 Failure to Study Multiple Load Levels:

- **TOPs do not always run their individual seasonal planning studies based on the multiple WECC base cases (heavy and light load summer, heavy and light load winter, and heavy spring), but, instead, may focus on only one load level. As a result, contingencies that occur during the shoulder seasons (or other load levels not studied) might be missed.**

Recommendation 7:

- **TOPs should expand the cases on which they run their individual planning studies to include multiple base cases, as well as generation maintenance outages and dispatch scenarios during high load shoulder periods.**

WECC created five base cases for the 2010-2011 season— heavy and light load summer, heavy and light load winter, and heavy spring—intended to capture the spectrum of possible loading configurations at different times of the year. The inquiry found that some of the affected TOPs deemed it unnecessary to run individual planning studies based on the multiple WECC base cases. Instead, these TOPs identified some subset of these base cases that they concluded were most relevant to their concerns and ran studies based on only that subset of base cases. Some TOPs employed only one base case—the heavy load summer base case—for planning the season during which the September 8, 2011 blackout occurred. By limiting the run of planning studies to a small subset of base cases, TOPs restrict their ability to anticipate and respond to contingencies arising in the context of load levels that vary significantly from those in the subset of base cases upon which their studies were predicated.

As noted above, September 8, 2011 was a very hot day in the region, and scheduled flows in the IID footprint were near record peaks. The high demand on September 8th was indeed similar to what would have been modeled in a heavy load summer seasonal study. The generation picture, however, was very different. By September 8, 2011 generation maintenance—which is not typically scheduled for summer peak days—had begun. The "heavy peak" summer study base cases that were actually used for September 8th therefore had built into them the incorrect assumption that there would be minimal maintenance—i.e., that most generation would be on line—and thus did not account for the normal resumption of facility maintenance in the shoulder season.

If IID's seasonal studies had assumed even a modest decrease in the available generation, they might have enabled IID to anticipate and prevent the events that occurred on its system. IID was unaware of the TDM maintenance outages, but if it had conducted a shoulder season study, it might have been operating in a mode that more accurately reflected actual operating conditions on that day and could have potentially avoided the overloading of CV transformers to the tripping point. This lack of awareness illustrates the risks of not separately modeling the shoulder months such as September, when facility maintenance has begun but demand could remain or become very high. During these times, generation to serve load may come from other areas, changing flow patterns from those that typically occur on a normal summer peak day in which most generation is on line.

Finding 8 Not Sharing Overload Relay Trip Settings:

- **In the seasonal planning process, at least one TOP did not share with neighboring TOPs overload relay trip settings on transformers and transmission lines that impacted external BPS systems.**

Recommendation 8:

- **TOPs should include in the information they share during the seasonal planning process the overload relay trip settings on transformers and transmission lines that impact the BPS, and separately identify those that have overload trip settings below 150% of their normal rating, or below 115% of the highest emergency rating, whichever of these two values is greater.**

As discussed in greater detail below, the relay trip settings of IID's CV 230/92 kV transformers were set very low, just above the facilities' emergency rating. These settings effectively meant that IID's system operators had very little time to respond to the overload resulting from the loss of H-NG beyond emergency ratings and could not rely on post-contingency mitigation. If IID's neighbors had been aware of the relay trip settings on these transformers when preparing their seasonal studies, they would have been able to plan for the possibility of the CV transformers tripping at a lower trip point.

As a general matter, TOPs should be aware of the relay trip settings of facilities in neighboring areas that have the potential to impact portions of the BPS within their own areas, regardless of whether or not those facilities have been defined as, or deemed to be, BES facilities. This concern is particularly acute where the overload trip points of the facility in question are set below 150% of their normal rating, or below 115% of their emergency rating, because, as discussed below, such settings sharply limit the amount of time available for operators to implement post-contingency mitigation measures. These settings require that all entities that could be affected are aware and able to implement pre-contingency mitigation.

Near-and Long-Term Planning

- ### Background

TPs and PCs conduct near- and long-term studies to ensure their systems are planned for reliable operation under normal operating conditions. In addition, the system facilities must remain stable in the event of single and multiple contingency scenarios. Near-term studies consider potential contingencies one to five years past the study date, and long-term studies consider potential contingencies six to ten years past the study date. The near- and long-term planning process in the WECC region involves a coordinated effort among individual TPs and PCs at the local level, Subregional Planning Groups (SPGs).[74] at the regional level, and WECC RE at the Interconnection-wide level. It is a multi-step process, performed annually.

First, TPs and PCs submit data about their internal networks to their respective SPG for each horizon year studied (i.e., years one through ten). These data include forecasted load levels and facilities projected to be in or out of service. Also, these data assume peak load conditions and, thus, reflects that most internal generation is online. Second, SPGs add information to these data based on their broad knowledge of planning projects and reliability issues within their respective regions. For example, an SPG

[74] There are five SPGs in the WECC region, each representing a specific area and composed of various members and stakeholders, including individual owners and operators of transmission networks, representatives of local government agencies, and independent developers. SPGs allow for the joint consideration of issues among individual members. APS, IID, and WALC are members of WestConnect, which performs the SPG function in the Southwest region. SDG&E and SCE are members of CAISO, which performs the SPG function in parts of California. The SPGs are involved in near- and long-term planning only and are unrelated to the SRSGs, discussed above, which deal with seasonal planning.

might add data for a particular horizon year based on its knowledge of a merchant generator's desire to connect to the grid. SPGs also consider future projects needed for reliability and the effect of environmental regulations on the future operation of generator units. Third, SPGs merge all of their members' cases to create a regional case. Fourth, WECC RE merges the various regional cases from all the SPGs to create the base case for each horizon year. WECC RE makes these cases available on its website for TPs, PCs, and SPGs to access. Finally, TPs and PCs add their own subtransmission facilities to the base cases to run their near- and long-term studies. TPs and PCs typically choose a list of contingencies to study based on past experience and engineering judgment.

As discussed below, this multi-step process has several shortcomings, which left the affected entities unprepared for the September 8th event.

Finding 9 Gaps in Near- and Long-Term Planning Process:

- **Gaps exist in WECC RE's, TPs' and PCs' processes for conducting near- and long-term planning studies, resulting in a lack of consideration for: (1) critical system conditions; (2) the impact of elements operated at less than 100 kV on BPS reliability; and (3) the interaction of protection systems, including RASs. As a consequence, the affected entities did not identify during the planning process that the loss of a single 500 kV transmission line could potentially cause cascading outages. Planning studies conducted between 2006 and 2011 should have identified the critical conditions that existed on September 8th and proposed appropriate mitigation strategies.**

Recommendation 9:

- **WECC RE should take actions to mitigate these and any other identified gaps in the procedures for conducting near- and long-term planning studies. The September 8th event and other major events should be used to identify shortcomings when developing valid cases over the planning horizon and to identify flaws in the existing planning structure. WECC RE should then propose changes to improve the performance of planning studies on a subregional- and Interconnection-wide basis and ensure a coordinated review of TPs' and PCs' studies. TOPs, TPs and PCs should develop study cases that cover critical system conditions over the planning horizon; consider the benefits and potential adverse effects of all protection systems, including RASs, Safety Nets (such as the SONGS separation scheme), and overload protection schemes; study the interaction of RASs and Safety Nets; and consider the impact of elements operated at less than 100 kV on BPS reliability.**

The affected entities' near- and long-term planning studies for horizon year 2011 (i.e., the studies conducted in 2001 through 2010) did not identify that the loss of a single 500 kV line in APS's territory would cause cascading outages across the territories of SDG&E, CFE, IID, and WALC. Several gaps in the near- and long-term planning process contributed to these omissions. First, TPs and PCs submit peak load data to

WECC for incorporation into the base case and, thus, the data assume that most internal generation is online to meet peak conditions. As a result, the models for 2011 did not contain accurate, realistic representations of online generation. Running studies under the assumption that most generation is online provided an unrealistic portrayal of system transfers on the day of the event.

Indeed, system transfers following the loss of H-NG were higher than the transfers seen in the base case used for near- and long-term studies. Significant flows from H-NG transferred across IID's and WALC's systems and onto Path 44. Flow on Path 44 increased by approximately 84% following the loss of the line. These large system transfers went undetected in near- and long-term studies, and the affected entities were not alerted to the need to plan for these critical system conditions. To avoid this problem in the future, TPs and PCs should study more generation dispatch scenarios to provide a more realistic projection of system transfers following contingencies.

Second, TPs and PCs do not run a full list of external contingencies during the near- and long-term planning process. Instead, they rely on experience and engineering judgment, focusing on previously identified contingencies. This can be particularly problematic in today's operating environment in which the nature and limitations of the system are rapidly changing. For example, as part of its near- and long-term planning IID studied potential contingencies on four WECC Rated Paths, but did not study the loss of H-NG. As a result, IID was not prepared for the effect on its system when that line tripped. Also, while IID's CV 230/92 kV transformers are included in the base case, some of the affected TPs and PCs did not study the potential loss of these facilities. By not considering a complete list of external contingencies that could impact their systems, TPs' and PCs' studies for horizon year 2011 were not sufficient to identify and plan for the impact of external contingencies on their internal systems or internal contingencies on neighboring systems.

Third, TPs and PCs do not study external subtransmission facilities in the near- and long-term planning process. Individual TPs and PCs add their own subtransmission facilities after the base case has been created by WECC RE, but do not add external subtransmission equipment. If external subtransmission systems were included in the base case, entities could identify the parallel flow on such lower-voltage systems that can result from transmission contingency outages. This consideration is particularly important for lower voltage systems that parallel external high voltage systems. For example, when APS's H-NG tripped, approximately 12% of its flow transferred to IID's 92 kV system. This increased flow and overloading on IID's system had a ripple effect, causing cascading outages throughout neighboring territories. Because the affected entities did not study external subtransmission systems in their near- and long-term studies, they did not identify the potential for overloading on IID's 92 kV system or the impact on their systems from this overloading.

Fourth, TPs and PCs do not sufficiently study the interaction of protection systems in external networks in their near- and long-term planning studies. For example, some of the affected TPs and PCs did not study the interaction between the overload protection on IID's three 230/92 kV transformers, or between the protection on these transformers and the S Line RAS. Based on the pre-event conditions, the loss of one CV transformer would automatically result in the loss of the second, followed automatically by the loss of the Ramon transformer, which in turn, would result in either voltage collapse and load shedding, or overloading on the S Line. The S Line RAS is designed to mitigate overloads by tripping generation in Mexico that supplies power to IID. However, operation in this manner only served to further overload IID and WALC facilities and exacerbate system conditions on the day of the event. The affected entities should have studied the interaction of these schemes to prepare for the impacts on their systems.

Finding 10 Benchmarking WECC Dynamic Models:

- **The inquiry obtained a very good correlation between the simulations and the actual event until the SONGS separation scheme activated. After activation of the scheme, however, neither the tripping of the SONGS units nor the system collapse of SDG&E and CFE could be detected using WECC dynamic models because some of the elements of the event are not explicitly included in those models. Sample simulations of the islanded region showed that by adding known details from the actual event, including UFLS programs and automatic capacitor switching, the simulation and event become more closely aligned following activation of the SONGS separation scheme.**

Recommendation 10:

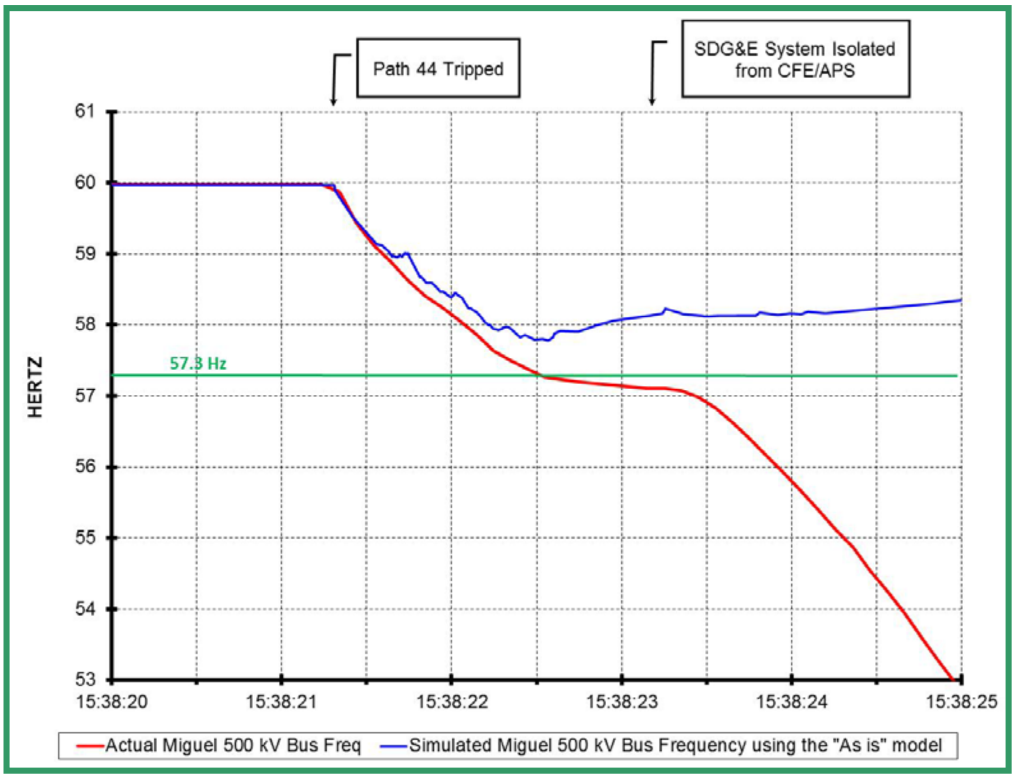
- **WECC dynamic models should be benchmarked by TPs against actual data from the September 8th event to improve their conformity to actual system performance. In particular, improvements to model performance from validation would be helpful in analysis of under and/or over frequency events in the Western Interconnection and the stability of islanding scenarios in the SDG&E and CFE areas.**

The inquiry simulated the dynamic system response of the September 8th event from prior to the loss of H-NG through the separation of Path 44 and the unsuccessful islanding of SDG&E and CFE. The team obtained very good correlation between the simulation model and the actual event until the SONGS separation scheme activated. However, neither the tripping of the SONGS units nor the system collapse of SDG&E and

CFE could be predicted using existing WECC dynamic models entities use to perform near- and long-term planning.

This inability to use the existing system models to reproduce the actual event is also evident in the post-event analysis that was prepared by SDG&E on the effectiveness of UFLS programs following the September 8th event.[75] The SDG&E post-event analysis shows that the UFLS performance should have prevented the SDG&E system from frequency collapse, similar to the "as is" results shown in ***Figure* 14**, below. However, the SDG&E analysis does not explain why the simulation results are so different than the actual system responses—i.e., successful islanding operation versus system collapse.

Figure 14: Actual and Simulated Frequency at Miguel 500 kV Bus



The inquiry's Modeling and Simulation team was able to obtain a simulation more closely aligned with actual measured performance by performing several sensitivity

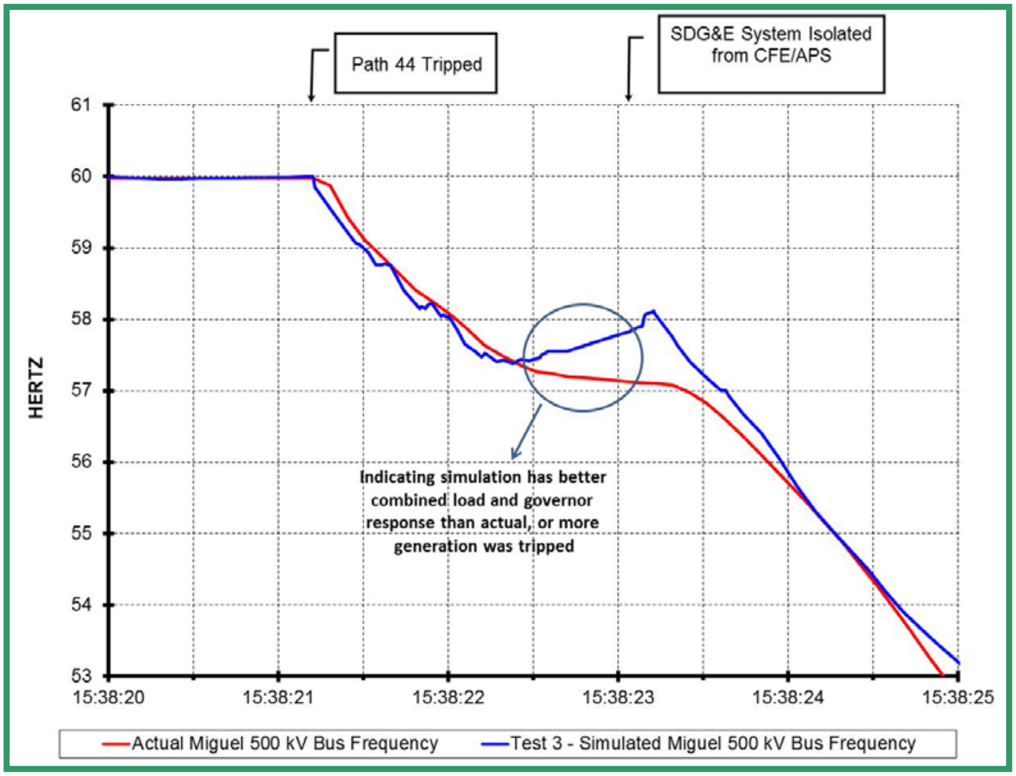
[75] Preliminary Analysis of SDG&E Off-Nominal UFLS Program Effectiveness Following September 8, 2011 Pacific Southwest Event, Performed by SDG&E, December 7, 2011.

studies and adding details from the actual event, including UFLS performance, PMU data, and generation tripped in CFE's and SDG&E's territories. For example, one sensitivity study (referred to here as "Test 3") simulated approximately:

a) 3,080 MW of UFLS in SDG&E 1.3 seconds after Path 44 tripped (compared to 2,760 MW in "as-is" case)
b) 520 MW of UFLS in CFE after Path 44 tripped, but prior to SDG&E separation from CFE/APS (compared to 900 MW modeled in "as-is" case)
c) 589 MW of generation tripped in CFE after Path 44 tripped, but prior to SDG&E separation from CFE/APS (compared to zero in "as-is" case)
d) 1,000 MW of generation tripped in SDG&E immediately after SDG&E separated from CFE/APS (compared to zero in "as-is" case)

***Figure* 15**, below, shows results of "Test 3." As can be seen, this simulation more closely follows the actual event than the "as-is" model used in Figure 14.

Figure 15: Miguel Frequency Actual and Simulated for "Test 3"



The simulation studies explain the ineffectiveness of the UFLS program, despite up to 75% of SDG&E load that was shed within 1.3 seconds of the SONGS separation scheme operating. The simulation analysis confirmed findings in the inquiry's SOE that the frequency collapse was caused by generation trips and UFLS misoperations within

CFE shortly after Path 44's separation, followed by additional generation trips within SDG&E around the time it separated from CFE/APS.

B. Situational Awareness

Background

TOPs, BAs, and RCs have system operators who constantly monitor their networks to maintain situational awareness of system conditions, identify potential system disturbances, and institute mitigating measures, as necessary. The affected entities utilize a range of tools to perform these functions. All of the entities use SCADA systems as their main monitoring tool. SCADA systems typically consist of a central computer that receives information from various RTUs and intelligent electronic devices (IEDs), located throughout the system. SCADA systems provide control center operators with real-time measurements of system conditions and can send alarms to signal a problem.

Most of the affected entities also use several other tools to study and analyze the information received from their SCADA systems. Two of the most important tools are State Estimator and RTCA. State Estimator gathers the available measurements from the SCADA system and calculates estimated real-time values for the whole system. RTCA then takes the information from State Estimator and studies "what if" scenarios. For example, RTCA determines the potential effects of losing a specific facility, such as a generator, transmission line, or transformer, on the rest of the system. In addition to studying the effects of various contingencies, RTCA can prioritize contingencies. It can also provide mitigating actions and send alarms (visual and/or audible) to operators to alert them to potential contingencies.

While most of the affected entities have and use these tools, the inquiry identified several concerns with entities' ability to adequately monitor, identify, and plan for the next most critical contingency in real time. Several areas for improvement are described in the findings below.

PMUs did not play a role in observing the September 8th event in real time, but may prove increasingly important in situational awareness. Of the affected entities, CAISO, SCE, and APS are equipped with PMUs. PMUs are widely distributed throughout WECC as the result of a WECC-wide initiative known as the Western Interconnection Synchrophasor Program (WISP). Their high sampling speed (up to 30 samples per second) and excellent GPS-based time synchronization offer new granularity in information about voltage phase angles and other grid conditions. PMUs are expected to be used to identify and monitor for grid stress, grid robustness, dangerous oscillations, frequency instability, voltage instability, and reliability margins. While not yet sufficiently integrated to have been used by the affected entities in their control rooms on September 8th, as discussed earlier, PMU data proved valuable in constructing the sequence of events and other post-event analysis.

Finding 11 Lack of Real-Time External Visibility:

- **Affected TOPs have limited real-time visibility outside their systems, typically monitoring only one external bus. As a result, they lack adequate situational awareness of external contingencies that could impact their systems. They also may not fully understand how internal contingencies could affect SOLs in their neighbors' systems.**

Recommendation 11:

- **TOPs should engage in more real-time data sharing to increase their visibility and situational awareness of external contingencies that could impact the reliability of their systems. They should obtain sufficient data to monitor significant external facilities in real time, especially those that are known to have a direct bearing on the reliability of their system, and properly assess the impact of internal contingencies on the SOLs of other TOPs. In addition, TOPs should review their real-time monitoring tools, such as State Estimator and RTCA, to ensure that such tools represent critical facilities needed for the reliable operation of the BPS.**

Although all of the affected TOPs use SCADA to monitor their own systems, some TOPs' situational awareness is hindered by their limited visibility into neighboring systems. Some of the affected TOPs' real-time external visibility is limited to one or two buses outside their systems. The September 8, 2011, event demonstrated that more expansive visibility into neighboring systems is necessary for these TOPs to maintain situational awareness of external conditions and contingencies that could impact their systems and internal conditions and contingencies that could impact their neighbors' systems. During the 11-minute time span of the September 8th event, entities observed changes in flows into their systems, but were unable to understand the cause or significance of these changes and lacked sufficient time to take corrective actions. If affected entities had seen and run studies based on real-time external conditions prior to the event, they could have been better prepared to redispatch generation or take other control actions and deal with the impacts when the event started.

IID, for example, is adjacent to APS, and the changes in flows on APS's system, especially on its 500 kV lines, can affect the flows on IID's system and vice versa. Yet, IID's visibility into APS's system is limited to information about the tie line between them. In fact, IID's visibility into all of its neighbors is limited to one or two buses outside its system.[76] As a result, IID did not learn in real-time that H-NG tripped. IID also did not understand prior to the event how changes in flows or the loss of H-NG would affect its system. Immediately after H-NG tripped, IID observed loading on its CV transformers escalate rapidly, but it had not been prepared for this escalation.

If IID had greater visibility into APS's system and IID had an equivalent on its RTCA that modeled the external network using APS's real-time data instead of pseudo-generators modeled at the end of each tie line, IID's RTCA could have more accurately studied the results of a post-contingency loss of H-NG on its system before it occurred. After seeing the more accurate RTCA results, IID could have initiated appropriate control actions before H-NG tripped. Also, having real-time status of the H-NG would have better prepared IID to deal with the effects of its loss in real time.

In addition to IID not having adequate situational awareness of APS's system, the affected TOPs and BAs external to IID were not aware in real time of the effect of the post-contingency loss of IID's three 230/92 kV transformers on their systems. Losses of the CV and Ramon transformers can cause SOL violations on neighboring systems. Indeed, on September 8th, these transformer outages had a significant ripple effect and led to the cascading nature of the event. Yet, entities outside IID's footprint were not prepared for these outages and, except for WECC RC, were unaware of the outages in real time because of a lack of adequate visibility into IID's system. For example, at the time of the event, CAISO's visibility into IID's system stopped at the tie line into IID's El Centro station.

The September 8th event exposed the negative consequences of TOPs having limited external visibility into neighboring systems. Providing TOPs with the ability to observe and model external system conditions and events on a continuous real-time basis will allow them to study and plan for the impact of external conditions and contingencies before it is too late to react, as was the case on September 8th.

---

76 IID has made efforts, even before the September 8th event, to receive more data points from adjacent utilities and is currently continuing this effort with all of its neighbors.

Finding 12 Inadequate Real-Time Tools:

- **Affected TOPs' real-time tools are not adequate or, in one case, operational to provide the situational awareness necessary to identify contingencies and reliably operate their systems.**

Recommendation 12:

- TOPs should take measures to ensure that their real-time tools are adequate, operational, and run frequently enough to provide their operators the situational awareness necessary to identify and plan for contingencies and reliably operate their systems.

Although many of the affected TOPs have and use real-time tools such as State Estimator and RTCA, some of the tools are not adequate or operational to provide the situational awareness necessary to effectively monitor and operate their systems. Also, some TOPs run or view these tools infrequently, while others run RTCA, for example, every five minutes.

The alarming function on IID's RTCA provides an example of a real-time tool that does not adequately maximize situational awareness capabilities. IID's RTCA does not provide operators with any audible alarms or pop-up visual alerts when an overload is predicted to occur. Instead, IID's RTCA uses color codes on a display that the operator must call up manually to learn of significant potential contingencies. For example, IID's RTCA might show that on the next contingency, a specific element will become overloaded. However, as currently designed, the operator must go to the specific page related to this element to view this result. The result will be color coded on this page, but this code does not function as an alarm.

This design feature of IID's RTCA had negative consequences on the day of the event. Forty-four minutes prior to the loss of H-NG, IID's RTCA results showed that the N-1 contingency loss of the first CV transformer would result in overloading of the second CV transformer to its tripping point. If IID had taken action at this pre-contingency stage, it could have avoided the loss of both transformers. The IID operator, however, did not view the appropriate RTCA display and, therefore, was not alerted to the need to take action. If the operator had reviewed the RTCA results and taken necessary corrective actions, he could have relieved loading on the transformers at this pre-event stage, and thus mitigated the severe effects on the CV transformers that resulted when H-NG tripped.[77]

[77] Since the event, IID has initiated changes to its RTCA program. First, it is working with a vendor to install an audible alarm feature. Second, IID has instructed its operators to constantly leave the RTCA result display screen on, rather than periodically calling it up.

One affected entity, APS, has State Estimator and RTCA capability, but neither tool is operational. As a result, APS has limited capability to monitor and operate its system to withstand potential real-time contingencies. Instead of using RTCA, APS relies on a set of previously studied contingencies and pre-determined plans to mitigate them. These studies are included in a manual that is created annually and usually updated several times a year.[78] By relying on pre-determined studies, APS cannot account and prepare for all potential contingency scenarios in real time. RTCA would provide APS with a more realistic analysis of its next potential contingency because the RTCA analysis is based on real-time conditions, as measured by State Estimator. Without RTCA, APS operators are not fully prepared to identify and plan for the next most critical contingency on its system.

RTCA would have allowed APS operators to study the impact of the loss of its H-NG. Although APS could have studied this contingency in its manual and seasonal studies, it could not have studied it *based on real-time operating conditions* that only State Estimator can provide. For example, APS's manual and seasonal studies did not study the loss of H-NG together with the multiple generator outages that existed on the day of the event.[79] As a result, APS was unprepared for the actual consequences of losing H-NG on September 8, 2011, including overloads on IID's 92 kV system and potential difficulty reclosing H-NG due to large phase angle differences.[80]

---

78 APS can also ask WECC RC or an APS engineer for a current-day study, but it usually relies on its manual for operations. APS also relies on WECC RC to notify it of any major post-contingency issues detected by WECC RC's RTCA results, but WECC RC might not consistently and promptly notify individual TOPs of all major issues.

79 APS has indicated that it has had difficulty obtaining generator outage information from other BAs due to market and/or tariff concerns.

80 Prior to the event, APS had been working with a vendor to build its RTCA capability and, since the event; it has accelerated its efforts to make RTCA operational.

Finding 13 Reliance on Post-Contingency Mitigation Plans:

- **One affected TOP operated in an unsecured N-1 state on September 8, 2011, when it relied on post-contingency mitigation plans for its internal contingencies and subsequent overload and tripping, while assuming there would be sufficient time to mitigate the contingencies. Post-contingency mitigation plans are not viable under all circumstances, such as when equipment trips on overload relay protection that prevents operators from taking timely control actions. If this TOP had used pre-contingency measures on September 8th, such as dispatching additional generation, to mitigate first contingency emergency overloads for its internal contingencies, the cascading outages that were triggered by the loss of H-NG might have been avoided with the prevailing system conditions on September 8, 2011.**

Recommendation 13:

- TOPs should review existing operating processes and procedures to ensure that post-contingency mitigation plans reflect the time necessary to take mitigating actions, including control actions, to return the system to a secure N-1 state as soon as possible but no longer than 30 minutes following a single contingency. As part of this review, TOPs should consider the effect of relays that automatically isolate facilities without providing operators sufficient time to take mitigating measures.

Before September 8, 2011, IID consistently relied on post-contingency mitigation plans, rather than proactively responding on a pre-contingency basis, for RTCA results showing that the N-1 loss of one CV transformer would result in overloading on the second CV transformer. Post-contingency plans can work to prevent a second contingency as long as operators have sufficient time to take mitigating actions. Post-contingency mitigation is not an appropriate choice for the CV transformers, which are set to trip by overload protection relays without allowing operators enough time to take mitigating actions. Specifically, the transformers' overload protection scheme is set with a thin margin between the emergency rating and the relay trip point. The normal rating of the transformers is 150 MVA, the emergency rating is 165 MVA, and the relay trip point is set at 190.5 MVA, or 127% of the normal rating. Thus, when the transformers reach their emergency rating, operators may have the mistaken belief that they have sufficient time to take mitigating actions, when, in fact, the operators will have very little time before the transformers will trip offline, because they will soon reach the relay trip setting. As shown below, pre-contingency mitigation measures are necessary when operators are faced with settings that leave such little margin between the emergency rating and overload trip point.

On multiple days during the summer of 2011, IID's RTCA results showed that an N-1 contingency tripping of one of the CV transformers would result in overloading on the second transformer. IID continued to operate in this state on multiple days without taking any pre-contingency mitigating actions. For example, IID did not dispatch additional generation on a pre-contingency basis to control the loading on one CV transformer to prevent overloading on the second CV transformer. There were potentially severe consequences of not taking pre-contingency actions. Specifically, IID's next-day study for September 8th detailed that the loss of both CV transformers would overload: (1) IID's Ramon transformer to its trip point; and (2) the S Line, which, in turn, would cause the S Line RAS to trip generation in Mexico that supplies power to the Imperial Valley substation. In short, on multiple days in summer 2011, IID's RTCA results showed that the loss of one CV transformer would overload the second transformer, and IID's next-day study revealed the cascading outages that would stem from the loss of both transformers. Yet, IID did not institute pre-contingency mitigating measures, such as dispatching additional generation.

Instead, IID relied on post-contingency plans. On most days in summer 2011, the level of overloading on the CV transformers gave IID just enough time to successfully use a post-contingency mitigation plan to start generation after the loss of the first transformer to avoid the loss of the second transformer. However, on at least two days observed by the inquiry, a post-contingency plan would not allow the operator enough time to implement necessary procedures to mitigate the problem. On those two days, the loading on both CV transformers was high enough that only pre-contingency mitigation measures could have prevented the loss of the second transformer upon the loss of the first. On the first of those two days, IID was simply fortunate that the N-1 contingency loss of the first transformer never occurred. The second of the two days was September 8, 2011.

Forty-four minutes prior to the loss of H-NG, IID's RTCA results showed that the N-1 contingency loss of the first CV transformer would result in overloading of the second transformer to approximately 139% of its normal rating—leading to the loss of the transformer by relay action. If IID had taken action at this pre-contingency stage, IID might have been able to avoid the loss of both transformers.[81] After H-NG tripped, the relays took less than 40 seconds to trip both CV transformers. Operators had no time to mitigate the overloads before the transformers were removed from service.

[81] The inquiry understands that the IID operator did not see these RTCA results and, thus, would not have known of the need for pre-contingency mitigating measures. There is no indication, however, that IID would have used pre-contingency measures regardless of the results. IID consistently relied on post-contingency measures.

Finding 14 WECC RC Staffing Concerns:

- **WECC RC staffs a total of four operators at any one time to meet the functional requirements of an RC, including continuous monitoring, conducting studies, and giving directives. The September 8th event raises concerns that WECC RC's staffing is not adequate to respond to emergency conditions.**

Recommendation 14:

- **WECC RC should evaluate the effectiveness of its staffing level, training and tools. Based on the results of this evaluation, it should determine what actions are necessary to perform its functions appropriately as the RC and address any identified deficiencies.**

WECC RC performs its reliability coordination functions through two offices. Although each office is capable of monitoring the entire Interconnection, during normal operations the offices have primary responsibility for monitoring different parts of the Western Interconnection. WECC RC's Vancouver, Washington, office is primarily responsible for monitoring the Pacific Northwest (excluding PacifiCorp East), California, and CFE's territory in Mexico. WECC RC's Loveland, Colorado, office is primarily responsible for monitoring the Desert Southwest area, Rocky Mountain area, PacifiCorp's East area, Sierra Pacific Power Company's area, IID's area, and the Los Angeles intermountain area. Each office staffs two on-shift operators at all times. Each center dedicates an operator to the real-time desk (real-time operator) and the other operator to the study desk (study desk operator).

The real-time operator's primary responsibilities include monitoring limits and operating parameters, identifying exceedances, evaluating mitigation plans, and directing corrective actions. The study desk operator's primary responsibilities include monitoring expected post-contingency conditions to identify potential exceedances, evaluating actions being taken, and directing corrective action as necessary. The study desk operator also reviews WECC RC's next-day study for accuracy, conducts real-time studies to evaluate system conditions, and monitors EMS applications, such as RTCA, to identify any performance issues and request corrective actions, as necessary. The real-time operator and study desk operator also have some joint responsibilities, including reporting events that impact the BPS, identifying events or system conditions that require notification to adjacent RCs, and monitoring and testing primary and backup internal communication systems. Through these responsibilities, WECC RC is responsible for the reliable operation of the BPS in the WECC footprint, and it has the ultimate authority to prevent or mitigate emergency operating situations in both next-day and real-time timeframes.

In addition, WECC RC is responsible for providing information to the entities in its footprint, including the 53 TOPs and 37 BAs. Some of this information is provided over the telephone. During the event, in addition to performing the many RC functions they are responsible for performing, the RC operators had to answer phone calls providing or seeking information on the disturbance.

Given WECC RC's responsibility and authority, four total operators—two in each regional office—might not be sufficient to effectively perform its function, particularly during emergency conditions. Several examples from the September 8th event highlight this concern.

First, after the loss of H-NG, many alarms began sounding in WECC RC's control rooms, as voltage dropped and facilities overloaded. With so many alarms sounding in an emergency situation, the real-time operator had a difficult time prioritizing which alarms to monitor. WECC RC has eight unique categories, or "buckets," of alarms within its EMS applications, grouped according to importance. Buckets 1 and 2 contain the highest priority alarms. Bucket 1 includes all 500 and 345 kV circuit breaker status changes, frequency and Path violations, status of generators greater than 50 MW and associated circuit breakers, and critical bus voltages. Bucket 2 includes all 220/230 kV circuit breaker status changes and automatic voltage regulator status.[82] Buckets 3 through 8 include lesser priority items, such as RAS status changes, non-critical bus voltages, and circuit breaker status changes below 220 kV. Operators receive audible alarms for buckets 1 and 2 and typically leave bucket 1's display on the screen constantly and use one other screen to display all other buckets. It is a constant process to continually monitor the alarms, even during normal operating conditions, and it might not be possible for one real-time operator to keep track of and prioritize multiple alarms sounding at once. Also, both operators had numerous phone calls to field from entities throughout the affected areas, reporting and requesting information. Overburdening the real-time operator in this way could undermine his or her ability to perform the critical functions of monitoring system conditions and directing necessary corrective actions. Accordingly, WECC RC should consider whether additional operators are necessary to adequately perform these functions.

A second indication that the current RC staffing levels might not be sufficient came during the September 8th event when the study desk operator had to abandon his duties in order to provide support to the real-time operator by fielding phone calls and monitoring conditions. On this day, the RC operators were able to call for an engineer to

[82] The CV 230/92 kV transformers are included in bucket 2.

conduct some studies. Because the September 8th event occurred during the afternoon, an engineer was available. Finding an engineer to substitute for the study desk operator may not always be so easy. Late at night and early in the morning, no engineers are on duty. That the study desk operator needed to leave his responsibilities to support the real-time operator may indicate that one real-time operator and one study desk operator per office might not be sufficient to fulfill WECC's reliability coordination functions.

Alternatively, additional training and enhanced tools may enable an entity to accomplish more with the same number of personnel. While the inquiry observed a sampling of WECC RC's tools to be adequate during its site visit, WECC RC is in the best position to identify the combination of additional staff, enhanced tools, or training that best addresses the concerns identified by this report.

Finding 15 Failure to Notify WECC RC and Neighboring TOPs Upon Losing RTCA:

- **On September 8, 2011, at least one affected TOP lost the ability to conduct RTCA more than 30 minutes prior to and throughout the course of the event due to the failure of its State Estimator to converge. The entity did not notify WECC RC or any of its neighboring TOPs, preventing this entity from regaining situational awareness.**

Recommendation 15:

- **TOPs should ensure procedures and training are in place to notify WECC RC and neighboring TOPs and BAs promptly after losing RTCA capabilities.**

When entities temporarily lose their RTCA capability due to technical issues, they become blind to the next most severe contingency on their system, and they do not know what pre-contingency measures might be necessary. Thus, when they lose RTCA, they must take immediate action to try to regain their situational awareness. For example, after losing RTCA an entity should contact WECC RC, so the RC can monitor the entity's system and inform it of any significant issues. In such instances, the RC should also notify neighboring entities of any major contingencies that could impact their systems.

Between 13:59 and the start of the event on September 8, 2011, WALC lost its RTCA when its State Estimator stopped solving.[83] As a result, WALC lost its ability to identify and study post-contingency violations and to take pre-contingency mitigating measures, as necessary. When it lost its RTCA, WALC should have contacted WECC RC and asked it to monitor WALC's area. WECC RC could have then notified WALC regarding any significant problems and could have also contacted WALC's neighbors if it

[83] By not solving, or converging, the State Estimator stopped providing estimated values for the system.

learned of any SOLs in WALC that were impacting the neighbors' systems.[84] Prior to the event on September 8, 2011, WALC experienced several post-contingency SOL violations, but, without its RTCA capability, remained unaware of them. WECC RC's RTCA results showed these violations. WALC, however, did not notify WECC RC when it lost RTCA and, thus, WECC RC was unaware that it should notify WALC of the violations. An entity should never be operating in an unknown state, as WALC was when it lacked functional RTCA and State Estimator, and did not ask any other entity to assist it with situational awareness.

Finding 16 Discrepancies Between RTCA and Planning Models:

- **WECC's model used by TOPs to conduct RTCA studies is not consistent with WECC's planning model and produces conflicting solutions.**

Recommendation 16:

- **WECC should ensure consistencies in model parameters between its planning model and its RTCA model and should review all model parameters on a consistent basis to make sure discrepancies do not occur.**

The usefulness of RTCA study results and other real-time studies depend on the models used in the studies. Inaccurate models jeopardize the accuracy of studies, as well as entities' ability to respond appropriately to potential contingencies identified by the studies. The inquiry's simulation of the September 8th event discovered that a discrepancy exists between WECC RC's model used to conduct RTCA studies and the model used for WECC's planning studies. Specifically, the impedance of IID's CV transformers differed by a factor of two between the WECC models. WECC's planning model has an impedance of 0.1 per unit, while WECC RC's RTCA model has an impedance of 0.05 per unit. This difference resulted in an error of approximately 16% in the RTCA model compared to the planning model with respect to loading on the CV transformers.

Although the inquiry did not perform a comprehensive comparison of all parameters in WECC's various models, this discrepancy between the RTCA and planning models on such important facilities calls into question the validity of other parameters in WECC's models.

I. System Analysis

[84] While not at issue in this event, the RC should also notify TOPs if it loses its RTCA, so that TOPs know that the RC is not able to observe their systems.

Consideration of BES Equipment

- ### Background

The BES is generally defined as all facilities operating at voltages above 100 kV, although certain sub-100 kV facilities with a significant impact on the BPS may be considered a part of the BES. Each RE currently determines its specific procedure for determining what is or is not BES. If a facility is not considered BES, relevant TOPs, BAs, and RCs may not study and model the impact of that facility.

Finding 17 Impact of Sub-100 kV Facilities on BPS Reliability:

- **WECC RC and affected TOPs and BAs do not consistently recognize the adverse impact sub-100 kV facilities can have on BPS reliability. As a result, sub-100 kV facilities might not be designated as part of the BES, which can leave entities unable to address the reliability impact they can have in the planning and operations time horizons. If, prior to September 8, 2011, certain sub-100 kV facilities had been designated as part of the BES and, as a result, were incorporated into the TOPs' and RC's planning and operations studies, or otherwise had been incorporated into these studies, cascading outages may have been avoided on the day of the event.**

Recommendation 17:

- **WECC, as the RE, should lead other entities, including TOPs and BAs, to ensure that all facilities that can adversely impact BPS reliability are either designated as part of the BES or otherwise incorporated into planning and operations studies and actively monitored and alarmed in RTCA systems.**

WECC RC, as well as TOPs and BAs impacted by the event, did not consider IID's 92 kV network and facilities (including the CV and Ramon transformers) as BES elements. IID did not reconsider whether the CV and Ramon transformers should be studied like BES facilities even after a draft study sponsored by CFE (and shared with IID) suggested the existence of a through-flow issue between the 500 kV substations at Devers and Imperial Valley, adversely impacting IID's 92 kV network (including the CV and Ramon transformers) during contingencies on BPS systems, including H-NG.[85] Because the Reliability Standards apply to BES facilities, if the CV transformers had been considered BES facilities, IID would have been required to study the impact they could have on BPS reliability.[86] Also, WECC RC and the affected TOPs would likely have included the facilities in their studies and been aware of the impact the loss of H-NG

---

[85] *See* CFE's Path 45 Increase Rating Phase 2 Study Report, January 12, 2011, at 19.

[86] *See, e.g.*, NERC Reliability Standard TOP-002-2b R11 (TOPs "shall perform seasonal, next-day, and current-day Bulk Electric System studies to determine SOLs").

would have on IID's 92 kV system, as well as the impact various trips within IID's 92 kV system would have on the rest of the BPS. The inquiry determined that, during the event, approximately 12% (168 MW) of the original flow on H-NG was transferred through IID's 92 kV system, making the 92 kV system part of a bulk power path as well as a significant looped transmission facility. The cascading outages that resulted from the loss of H-NG demonstrated the significant potential for IID's 92 kV system, including the CV transformers, to impact BPS reliability.

IROL Derivations

- ### Background

In order to ensure the reliable operation of the BPS, entities are required to identify and plan for IROLs, which are SOLs that, if violated, can cause instability, uncontrolled separation, and cascading outages. Once an IROL is identified, system operators are then required to create plans to mitigate the impact of exceeding such a limit to maintain system reliability.

Finding 18 Failure to Establish Valid SOLs and Identify IROLs:

- **The cascading nature of the event that led to uncontrolled separation of San Diego, IID, Yuma, and CFE indicates that an IROL was violated on September 8, 2011, even though WECC RC did not recognize any IROLs in existence on that day. In addition, the established SOL of 2,200 MW on Path 44 and 1,800 MW on H-NG are invalid for the present infrastructure, as demonstrated by the event.**

Recommendation 18.1:

- **WECC RC should recognize that IROLs do exist on its system and, thus, should study IROLs in the day-ahead timeframe and monitor potential IROL exceedances in real-time.**

Recommendation 18.2:

- **WECC RC should work with TOPs to consider whether any SOLs in the Western Interconnection constitute IROLs. As part of this effort, WECC RC should: (1) work with affected TOPs to consider whether Path 44 and H-NG should be recognized as IROLs; and (2) validate existing SOLs, and ensure that they take into account all transmission and generation facilities and protection systems that impact BPS reliability.**

The NERC Glossary defines an IROL as an SOL that, if violated, could expose a widespread area of the BPS to instability, uncontrolled separation, or cascading outages that adversely impact the reliability of the BPS. Each IROL is associated with a maximum time limit (Tv) that the IROL can be exceeded before the risk to the Interconnection or another RC area becomes greater than acceptable. The time limit can vary, but any IROL's Tv must be less than or equal to 30 minutes.[87]

For this event, the loss of H-NG should have been associated with an IROL with a Tv for this N-1 contingency of essentially no minutes, because the cascading from the loss of H-NG began within seconds. However, neither WECC RC nor any of the affected entities have previously identified this IROL. The WECC region historically has maintained an operating philosophy of not recognizing IROLs.[88] Instead, entities in the WECC region believe that as long as they operate within the conditions they have studied, they will not face the risk of IROLs and will not need to calculate IROLs. The September 8th event undermines this philosophy.

Prior to the event, the WECC system was supplying loads in the various balancing authority areas in the range of 85-95% of their recorded peak loads. The power flows on all the Paths in the WECC region were below their maximum ratings and voltages were within acceptable levels. In particular, the two major transmission corridors into the blackout area, namely Path 44 and H-NG, were loaded respectively to 1,302 MW and

---

[87] As defined by the NERC Glossary of Terms, an IROL's Tv is "[t]he maximum time that an [IROL] can be violated before the risk to the interconnection or other Reliability Coordinator Area(s) becomes greater than acceptable. Each [IROL's] Tv shall be less than or equal to 30 minutes." NERC Glossary of Terms, February 8, 2012, at 26.

[88] As described by WECC in a February 16, 2012 Webinar on its SOL Methodology revision, "***The WECC operating philosophy is to operate only in conditions that have been studied. Therefore, under these normal operating conditions, there are never IROL conditions (only SOLs).*** An IROL condition may be created by the occurrence of one or more unanticipated contingencies. When this occurs, under WECC Reliability Standards, bulk electric system operators are required to resolve the IROL condition within 20 minutes (stability) or 30 minutes (thermal)." http://www.wecc.biz/awareness/Reliability/Documents /SOL Methodology Presentation 02.16.2012.pdf (emphasis in original).

1,372 MW. Compared to their maximum SOL ratings of 2,200 MW and 1,800 MW, these loadings represent 59% and 78% of their maximum ratings—well within current limits. Path 44 and H-NG ratings of 2,200 MW and 1,800 MW may be invalid for the present infrastructure because cascading outages due to a single contingency occurred at loadings well below the SOL ratings.

During the 11-minute disturbance, the single contingency of the sudden loss of H-NG resulted in a series of cascading outages, with multiple elements exceeding their applicable ratings and leading to a widespread blackout of the area.

Accordingly, WECC RC should lead all relevant TOPs in the blackout area to study and report on the appropriateness of identifying Path 44 and H-NG as IROL paths. WECC RC should similarly assess transfer Paths outside this blackout area to ensure that there are no other similar reliability issues in the Western Interconnection. Existing operating processes and procedures should be reviewed to ensure corrective control capabilities are provided to system operators to enable them to return the system to a secure N-1 state as soon as possible, but no longer than 30 minutes following a single contingency.

WECC RC has a proposed new SOL Methodology document (current effective date of June 4, 2012), which acknowledges the need to establish IROLs, and the RC's responsibility to monitor IROLs.[89] It recognizes that "Stability SOLs may qualify as IROLs depending on the potential consequences of exceeding the limit and the impact on BES reliability. WECC RC makes this determination by collaborating with TOPs to understand the nature of the stability SOL, understanding the conditions that result in the establishment of the stability SOL, and determining the BES impacts of exceeding the stability SOL."[90] WECC RC also has a proposed multi-step process for determining whether thermal or voltage SOLs are IROLs. In general, WECC RC will look at whether potential IROLs cause "Widespread Adverse System Impacts," or "potential cascading." "Widespread Adverse System Impacts" is defined as "loading of three or more additional BES Facilities beyond 125% of their applicable emergency thermal Facility Rating, or [t]hree or more additional BES Facilities with bus voltages experiencing voltages less than 90%."[91] "Potential cascading" is defined as "when studies indicate that a

contingency results in severe loading on a Facility, triggering a chain reaction of Facility disconnection by relay action, equipment failure, or forced immediate manual disconnection of the Facility (for example, public safety concerns, or no time for the operator to implement mitigation actions)."[92]

Impact of Protection Systems on Event

Protection System Coordination

When an abnormal system condition is detected on the BPS, relay protection systems operate to isolate the problem while causing minimum disturbance to the power system. This requires the relay to be selective in determining which elements to interrupt. The only method of obtaining this selectivity is to perform coordination studies. The inquiry discovered that two TOs did not properly coordinate a protection system and a third TO implemented a protection scheme without performing any coordination studies at all. This lack of coordination of protection systems resulted in circuits unnecessarily being interrupted, which had an undesirable effect on BPS reliability during the September 8th event.

Finding 19 Lack of Coordination of the S Line RAS:

- **Several TOs and TOPs did not properly coordinate a RAS by: (1) not performing coordination studies with the overload protection schemes on the facilities that the S Line RAS is designed to protect; and (2) not assessing the impact of setting relays to trip generation sources and a 230 kV transmission tie line prior to the operation of a single 161/92 kV transformer's overload protection. As a result, BES facilities were isolated in excess of those needed to maintain reliability, with adverse impact on BPS reliability.**

Recommendation 19:

- The TOs and TOPs responsible for design and coordination of the S Line RAS should revisit its design basis and protection settings to ensure coordination with other protection systems in order to prevent adverse impact to the BPS, premature operation, and excessive isolation of facilities. TOs and TOPs should share any changes to the S Line RAS with TPs and PCs so that they can accurately reflect the S Line RAS when planning.

Operation of the S Line RAS isolates facilities beyond what is necessary to ensure reliability. The S Line RAS is a directional overload scheme, located at the Imperial Valley substation, which is jointly owned by SDG&E and IID. The S Line RAS was originally implemented to protect the sole 230/161 kV transformer at El Centro from

---

92 *Id.*

overloads due to increased flow on the S Line.[93] At the time, this was the only transfer point from the 230 kV line to the 161 kV system, and subsequently the 92 kV system, in IID's southern area. After implementing this RAS, IID has since installed a 230/92 kV transformer at El Centro, providing another path from the 230 kV system to the lower voltage networks.

IID's current intention for the S Line RAS is to reduce loading on the S Line by tripping generation and, if insufficient to reduce flow, tripping the S Line at Imperial Valley Substation before transformer overload protection operates to trip the 161/92 kV transformer at El Centro. Tripping the S Line before allowing the El Centro 161/92 kV transformer's overload protection to take action effectively results in the removal of the 230 kV source at the El Centro substation, which normally feeds a 230/92 kV transformer and a 230/161 kV transformer. Thus, the design of the S Line RAS intentionally isolates networked BES facilities to mitigate an overload on a non-BES facility (El Centro 161/92 kV transformer) to support reliability of the local system. While this action alone does not constitute miscoordination, proper coordination of a RAS should take into account, through system studies, the potential impact on BPS reliability, including potential interaction with other RASs and protection systems.

During the September 8th event, the S Line RAS operated as designed, in that it tripped when it reached the settings that IID had prescribed. However, if one considers the purpose of the S Line RAS, which was to protect the El Centro transformer from overloads, the S Line RAS operated long before it was needed. At the time that the S Line RAS operated, the El Centro 161/92 transformer was only loaded to 38% of its normal rating, and its overload trip point is 178% of its normal rating. Thus, the El Centro 161/92 transformer could have carried at least four times as much load before the transformer's overload protection system would have operated. Even though the El Centro transformer that the S Line RAS was designed to protect was nowhere near overloading, the S Line RAS tripped important generation and a 230 kV line. This calls into question the coordination of the S Line RAS with the transformer overload protection systems at El Centro.

IID provided SDG&E with the S Line RAS settings to implement. IID did not perform any studies to coordinate the S Line RAS with IID's protection systems. SDG&E did some studies to verify that the RAS coordinated with SDG&E's protection systems. There is no indication that the S Line RAS was coordinated with IID's transformer

---

[93] The S Line RAS also serves as secondary protection for other IID facilities if a RAS on the Imperial Valley to Miguel 500 kV line fails to operate.

overload protection at the El Centro station at which the S Line terminates. At a minimum, IID, SDG&E and CAISO (as the TOP for SDG&E) should work together to ensure the proper coordination of the S Line RAS.

To make matters worse, during the September 8th event, San Diego was relying on generation at Imperial Valley from the south when the S Line RAS tripped that generation. Loss of the Imperial Valley generation caused San Diego to pull even more power from the north, increasing the loading on Path 44 and causing the SONGS separation scheme to further exceed its trip point. If not tripped by the S Line RAS, generation at Imperial Valley could have helped SDG&E survive after the operation of the SONGS separation scheme. The inquiry's simulation showed that, had the S Line RAS tripped only the S Line without tripping the generation, the SONGS separation scheme would not have operated, and only IID would have lost power.[94]

Finding 20 **Lack of Coordination of the SONGS Separation Scheme:**

- **SCE did not coordinate the SONGS separation scheme with other protection systems, including protection and turbine control systems on the two SONGS generators. As a result, SCE did not realize that Units 2 and 3 at SONGS would trip after operation of the separation scheme.**

Recommendation 20:

- **SCE should ensure that the SONGS separation scheme is coordinated with other protection schemes, such as the generation protection and turbine control systems on the units at SONGS and UFLS schemes.**

SCE, the TO and TOP of the SONGS separation scheme, did not perform any protection system coordination studies for the separation scheme it implemented at SONGS. The scheme is intended to isolate five 230 kV lines simultaneously if its preset value is exceeded for a sustained period. If SCE had coordinated the separation scheme with other protection and generation control systems at SONGS, it may have recognized the potential for the operation of the SONGS separation scheme to cause the SONGS generators to trip. Coordination in this context requires system studies to assess the impact of operation of the RAS on the power system, including potential interaction with other RASs and protection systems, such as UFLS schemes.

In addition to the consequences at SONGS itself, the lack of coordination of the systems means that, when the scheme operates, the system enters an unknown state.

---

[94] *See* footnote 53.

During the event, the operation of the protection scheme significantly contributed to the blackout of SDG&E, CFE, and Yuma—an effect neither coordinated nor adequately studied prior to the event. The inquiry's simulation indicates that SDG&E, CFE and, Yuma would not have been blacked out if the SONGS separation scheme had not operated, with limited impact to the rest of the Western Interconnection.

Finding 21 Effect of SONGS Separation Scheme on SONGS Units:

- **The SONGS units tripped due to their turbine control systems detecting unacceptable acceleration following operation of the SONGS separation scheme.**

Recommendation 21:

- **GOs and GOPs should evaluate the sensitivity of the acceleration control functions in turbine control systems to verify that transient perturbations or fault conditions in the transmission system resulting in unit acceleration will not result in unit trip without allowing time for protective devices to clear the fault on the transmission system.**

When the SONGS separation scheme operated, turbines at SONGS began to accelerate in excess of their control system setting causing both units to trip offline. The tripping of the SONGS units in this manner raises questions about the sensitivity of the turbine control system's settings. The units are expected to withstand severe faults on the transmission system and allow the transmission protection systems to operate without the generators tripping offline. The coordination required for this protection is not a traditional relay-to-relay coordination; rather, the setting for the acceleration function should be coordinated with capabilities of the turbine and with the system response anticipated following operation of transmission protection systems for faults under various system conditions. The setting should also be coordinated with the system response following operation of the SONGS separation scheme. Had the turbine control system acceleration function been coordinated in this manner, the trip of the units may have been avoided.

Protection System Studies

Finding 22 Lack of Review and Studying Impact of SPSs:

- **Although WECC equates SPSs with RASs, prior to October 1, 2011, WECC's definition of RAS excluded many protection systems that would be included within NERC's definition of SPS. As a result, WECC did not review and assess all NERC-defined SPSs in its region, and WECC's TOPs did not perform the required review and assessment of all NERC-defined SPSs in their areas.**

Recommendation 22:

- **WECC RE, along with TOs, GOs, and Distribution Providers (DPs), should periodically review the purpose and impact of RASs, including Safety Nets and Local Area Protection Schemes, to ensure they are properly classified, are still necessary, serve their intended purposes, are coordinated properly with other protection systems, and do not have unintended consequences on reliability. WECC RE and the appropriate TOPs should promptly conduct these reviews for the SONGS separation scheme and the S Line RAS.**

The NERC definition of an SPS concludes with "Also called Remedial Action Scheme."[95] This implies that all SPSs are RASs and vice versa, but prior to October 1, 2011, the WECC region did not equate SPSs with RASs.[96] WECC created four classifications of protection systems that fall under the NERC definition of SPS, and, instead of including all of these classifications in the RAS definition, WECC only identified a subset of those protection systems as RASs. Safety Nets, Wide Area Protection Systems (WAPS), and Local Area Protection Systems (LAPS) were excluded from the WECC definition of a RAS even though they are SPSs as defined by NERC.

For example, SCE did not study the impact of the SONGS separation scheme on BPS reliability because it believed, by classifying this scheme as a Safety Net, that it was not required to be studied. SCE also did not submit the separation scheme to WECC for review by the Remedial Action Scheme Reliability Subcommittee (RASRS). The inquiry determined that the SONGS separation scheme is indeed an SPS/RAS as defined by NERC, because it altered the BPS configuration by separating Path 44 and redistributing generation in the absence of any faulted equipment. WECC, SDG&E, and SCE did not study the impact that the SONGS separation scheme could have on BPS reliability and,

95 NERC Glossary of Terms, February 8, 2012, at 46.

96 On October 1, 2011, WECC revised its definition of RAS to include Safety Nets and Local Area Protection Schemes.

thus, were unaware of its severe impact on the BPS when the scheme operated: blacking out SDG&E and CFE and leading to the loss of the SONGS generators.

Another protection system that did not get the necessary scrutiny due to WECC's narrow definition of RAS was the S Line RAS. The S Line is a 230 kV transmission line that serves as a major tie between SDG&E & IID. It runs from IID's and SDG&E's jointly owned Imperial Valley station on one end to IID's El Centro station on the other. The S Line RAS, as IID and SDG&E called it, was classified as a LAPS by WECC, which called it the "S Line Scheme." Thus, the RAS received no periodic assessments. Like the SONGS scheme, the S Line RAS appears to be a SPS/RAS as defined by NERC, because it is an automatic protection system that took action other than isolating a faulted facility by tripping generation in Mexico for loading on a tie line between SDG&E and IID.

The S Line RAS was implemented for two reasons: (1) to protect IID's system from overload during an N-2 event at SDG&E's Miguel substation; and (2) to protect IID's lone 230/161kV transformer at El Centro from overloads due to generation additions at Imperial Valley substation. The inquiry questions whether the scheme is still necessary, as both of the concerns that originally triggered installation of the S Line RAS have been mitigated. IID added a new transformer bank at El Centro, mitigating the concern for overloads on the 230/161kV transformer. Also, reconfigurations at Miguel along with the modifications to a RAS at Miguel have mitigated the concern of adverse effects on IID's system as a result of an N-2 event at Miguel. Since LAPSs are not periodically reviewed, the arguably outdated S Line RAS was still active during the September 8th event, and its operation contributed to IID's uncontrolled separation and the operation of the SONGS separation scheme by tripping over 400 MW of generation before the S Line itself tripped. At a minimum, SDG&E, IID and CAISO should participate in the review of the S Line RAS.

The SPSs that operated during the event suggest that WECC's previous exclusion of certain NERC-defined SPSs from WECC's RAS definition had an adverse impact on BPS reliability.

Finding 23 Effect of Inadvertent Operation of SONGS Separation Scheme on BPS Reliability:

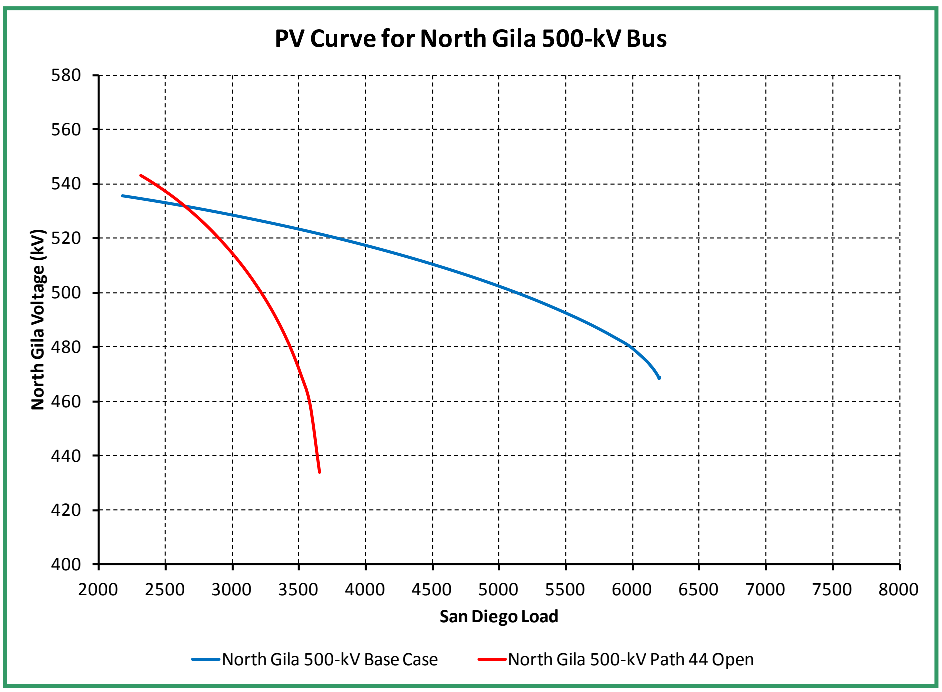
- **The inquiry's simulation of the event shows that the inadvertent operation of the SONGS separation scheme under normal system operations could lead to a voltage collapse and blackout in the SDG&E areas under certain high load conditions.**

Recommendation 23:

- **CAISO and SCE should promptly verify that the inadvertent operation of the SONGS separation scheme does not pose an unacceptable risk to BPS reliability. Until this verification can be completed, they should consider all actions to minimize this risk, up to and including temporarily removing the SONGS separation scheme from service.**

The inquiry conducted a simulation to evaluate what would happen if the SONGS separation scheme inadvertently operated during normal system operations (e.g., in the absence of any outages, overloads, or SOL violations). Based on this simulation, the inquiry determined that under certain high load conditions, the operation of the scheme could result in voltage collapse and a blackout in SDG&E's and CFE's territories. The inquiry conducted a voltage stability study using a Power-Voltage (P-V) curve to estimate the amount of SDG&E load that could reliably be supplied after an inadvertent operation of the SONGS separation scheme. The P-V curve below in ***Figure* 16** demonstrates that such operation would lead to a voltage collapse and a blackout in the SDG&E and CFE territories under certain high load conditions.

Figure 16: PV Curve for North Gila 500 kV Bus



Specifically, the system is most likely to collapse when the SDG&E load exceeds 3,500 MW. In 2010, SDG&E's load exceeded this amount for 851 hours,[97] meaning that the system was exposed to a potential blackout for approximately 10% of the year. This shows the potential risk to BPS reliability during normal system operations as a result of the inadvertent operation of the SONGS separation scheme. Accordingly, given the lack of studies done on the scheme, the inquiry recommends that the inadvertent operation of the SONGS separation scheme be reviewed promptly to ensure it does not pose an unacceptable risk to BPS reliability. Until this verification can be completed, CAISO and SCE should consider all actions needed to minimize this risk, up to and including temporarily removing the scheme from service.

Moreover, if SCE and CAISO were to decide to temporarily remove the scheme from the service, the inquiry does not believe that BPS reliability would be jeopardized. Indeed, inquiry simulations conducted for the day of the event show that if the scheme had not operated, the system, with the exception of collapses in the IID and Yuma areas, would have stabilized with minor overloads in the area around SONGS, acceptable voltages in the SDG&E area, and sufficient reactive margins in the critical portion of SCE's system.

Finding 24 Not Recognizing Relay Settings When Establishing SOLs:

- **An affected TO did not properly establish the SOL for two transformers, as the SOL did not recognize that the most limiting elements (protective relays) were set to trip below the established emergency rating. As a result, the transformers tripped prior to the facilities being loaded to their emergency ratings during the restoration process, which delayed the restoration of power to the Yuma load pocket.**

Recommendation 24:

- **TOs should reevaluate their facility ratings methodologies and implementation of the methodologies to ensure that their ratings are equal to the most limiting piece of equipment, *including relay settings*. No relay settings should be set below a facility's emergency rating. When the relay setting is determined to be the most limiting piece of equipment, consideration should be given to reviewing the setting to ensure that it does not unnecessarily restrict the transmission loadability.**

TOs are required to designate and share their facilities' SOLs. An SOL is the value that satisfies the most limiting element of a facility beyond which the system

[97] SDG&E Annual Electric Balancing Authority Area and Planning, FERC Form No. 714 (2010).

cannot operate reliably. The inquiry's relay loadability calculations show that APS failed to properly establish the SOL for two of its 500/69 kV transformers in North Gila, because the transformers' relay loadability or load limit was actually set below their emergency ratings. A facility cannot operate above its relay load limit, as operation in excess of a load limit results in the facility being removed from service. Thus, these settings prevented the TOP from taking advantage of the short term emergency ratings identified by the transformers' SOLs. These settings resulted in difficulties restoring power to the Yuma load pocket, as operators believed they could load the transformers up to their emergency rating. Instead, the transformers tripped below the emergency rating, delaying the restoration of power to Yuma.

If the SOL derivation had considered the transformer relay load limit, the TO could have (1) provided an SOL that accurately reflected the relay load limit so the system operator could have limited the transformer loading appropriately, or (2) reviewed the relay load limit to determine whether it unnecessarily limited the transformer loadability, and if so, raised the transformer relay setting threshold above the transformer emergency rating while coordinating the setting with the transformer short-time thermal capability.

Load-Responsive Phase Protection Systems Set Too Close to Normal or Emergency Ratings

BES facilities at a minimum are required to have normal and emergency ratings. The normal rating is a continuous rating or a rating that a facility can be operated to on a daily basis that specifies the amount of electrical loading a facility can support. The emergency rating specifies the level of electrical loading a facility can support for a finite period of time. Operating a facility beyond its normal and/or emergency rating for an extended period of time will expose certain equipment in that facility to the risk of thermal damage. In order to prevent thermal damage to facilities, some TOs implement overload protection systems that are designed to automatically isolate the facilities if operated beyond their emergency rating.

A problem arises when overload protection systems are set in close proximity to a facility's normal or emergency ratings. Setting the overload protection close to the normal or emergency ratings restricts facility loading and prevents operators from having sufficient time to take remedial action to mitigate an overload before the facility is automatically isolated by the overload protection system.[98] As the Commission stated

[98] NERC Reliability Standard PRC-023-1 R1.11 provides the following guidance on setting of overload protection systems on transformers: "Set the relays to allow the transformer to be operated at an overload level of at least

in Order No. 733, "manual mitigation of thermal overloads is best left to system operators, who can take appropriate actions to support Reliable Operation of the Bulk-Power System."[99] Protective relay settings limited transmission loadability with extremely conservative overload protection settings, resulting in cascading outages during the September 8th event. These settings resulted in facilities being automatically removed from service by relays before operators had an opportunity to take remedial action.

Finding 25 Margin Between Overload Relay Protection Settings and Emergency Rating:

- **Some affected TOs set overload relay protection settings on transformers just above the transformers' emergency rating, resulting in facilities being automatically removed from service before TOPs have sufficient time to take control actions to mitigate the resulting overloads. One TO in particular set its transformers' overload protection schemes with such narrow margins between the emergency ratings and the relay trip settings that the protective relays tripped the transformers following an N-1 contingency.**

Recommendation 25:

- **TOs should review their transformers' overload protection relay settings with their TOPs to ensure appropriate margins between relay settings and emergency ratings developed by TOPs. For example, TOs could consider using the settings of Reliability Standard PRC-023-1 R.1.11 even for those transformers not classified as BES. PRC-023-1 R.1.11 requires relays to be set to allow the transformer to be operated at an overload level of at least 150% of the maximum applicable nameplate rating, or 115% of the highest operator established emergency transformer rating, whichever is greater.**

Relay loadability calculations indicate that the relay settings on a number of transmission facilities limited transmission loadability to slightly above the emergency rating. For example, the relays on IID's CV transformers were set to trip at 127% of their normal rating. The parallel CV transformers were loaded to 130%, which was above their 127% overload relay trip point, immediately after the loss of H-NG. Both transformers tripped less than 40 seconds later. If the transformers' overload trip point had been in accordance with PRC-023-1 R.1.11, the trip point would not have been exceeded immediately after the loss of the H-NG, and IID operators might have had time to take actions to prevent cascading.[100]

150% of the maximum applicable nameplate rating, or 115% of the highest operator established emergency transformer rating, whichever is greater."

[99] *Transmission Relay Loadability Reliability Standard*, 130 FERC ¶ 61,221, at P 212 (2010).

[100] IID originally used conservative settings because the CV transformers are rare, expensive, load-serving transformers. IID has indicated, however, that it will increase the overload relay settings on the CV transformers

During the September 8th event, IID was unaware that the overload relay setting for the Ramon 230/92 kV transformer had been mistakenly set at 207% of its normal rating. IID intended the Ramon transformer to have been set to trip at 120% of its normal rating. After the event, IID reduced the Ramon transformer's trip setting from 207% to 120%, making it more likely to trip during high-loading conditions or conditions similar to those that precipitated the blackout, decreasing the opportunity for its operators to take mitigating actions during such conditions. This setting actually increased the risk of future cascading outages like the one which occurred on September 8, 2011.

Finding 26 Relay Settings and Proximity to Emergency Ratings:

- **Some TOs set relays to isolate facilities for loading conditions slightly above their thirty minute emergency ratings. As a result, several transmission lines and transformers tripped within seconds of exceeding their emergency ratings, leaving TOPs insufficient time to mitigate overloads.**

Recommendation 26:

- **TOs should evaluate load responsive relays on transmission lines and transformers to determine if the settings can be raised to provide more time for TOPs to take manual action to mitigate overloads that are within the short-time thermal capability of the equipment instead of allowing relays to prematurely isolate the transmission lines. If the settings cannot be raised to allow more time for TOPs to take manual action, TOPs must ensure that the settings are taken into account in developing facility ratings and that automatic isolation does not result in cascading outages.**

In addition to the problematic protection settings of the CV transformers, which precipitated the cascade, the inquiry discovered that several other facilities, including a number of IID's 161 kV transmission lines and two of WALC's 161/69 kV transformers, had relay protection settings which were only slightly above those facilities' emergency ratings. These conservative settings severely limited TOPs' response time before the facilities were isolated, preventing the operators from taking effective mitigating action against the cascade. While the inquiry did not determine whether less conservative relay settings on these other facilities would have mitigated the cascade, the applied settings nevertheless do not leave operators sufficient time to take mitigating steps to prevent or ameliorate the consequences of future events.

Angular Separation

to 150% of their normal rating, and will relocate an additional 230/92 kV transformer from another substation to CV.

When a transmission line trips or goes out of service, the phase angle will generally increase between its two terminal points. When angle differences become large, facilities connected to the system can lose synchronization, causing the system to become unstable. Also, if the phase angle is too large, closing the line breaker back into service with a large angle difference may result in damage to nearby generator turbine shafts, and the resulting power swings and oscillations could lead to system instability or collapse. To enable successful reclosing, studies should be run to determine the maximum phase angle difference allowable for a line to be closed back in and safeguards be put into place to prevent reclosure with excessive phase angle difference. Should the phase angle difference exceed the established limit, generation or load must be adjusted to reduce it to the level that allows the line to be closed.

Finding 27 Phase Angle Difference Following Loss of Transmission Line:

- **A TOP did not have tools in place to determine the phase angle difference between the two terminals of its 500 kV line after the line tripped. Yet, it informed the RC and another TOP that the line would be restored quickly, when, in fact, this could not have been accomplished.**

Recommendation 27:

- **TOPs should have: (1) the tools necessary to determine phase angle differences following the loss of lines; and (2) mitigation and operating plans for reclosing lines with large phase angle differences. TOPs should also train operators to effectively respond to phase angle differences. These plans should be developed based on the seasonal and next-day contingency analyses that address the angular differences across opened system elements.**

The inquiry's simulation shows that after H-NG tripped, the voltage phase angle between the two terminals increased from 20 degrees to approximately 72 degrees. On the day of the event, APS's synchro-check relay was set at 60 degrees,[101] meaning APS would not have been able to reclose H-NG until it reduced the phase angle difference from 72 to 60 degrees, or changed the relay setting to allow the breaker to close. Specifically, the 60 degree setting would not have allowed APS to reclose H-NG until appropriate generation on both sides of North Gila was dispatched or load reductions in the areas west of North Gila were implemented to reduce the difference of the voltage phase angle to 60 degrees.

[101] Based on additional studies, APS has since determined the maximum settings on its synchro-check relay at North Gila to allow a maximum phase angle difference of 75 degrees to reclose a line. To add margin, APS has implemented the relay setting at 70 degrees.

Although APS operators are trained to effectively respond to phase angle differences,[102] APS currently lacks the tools necessary to determine phase angle differences following the loss of a transmission line until the line is reenergized.[103] The training, therefore, does little good if the operators cannot determine whether a phase angle difference exists in the first place. Generally, APS operators can monitor phase angles through SCADA, but in order to receive and review this data, the transmission line must be energized. After H-NG tripped, and prior to reenergizing the line, for example, APS had no way to know if the line could be reclosed within the permissive 60 degree setting of its synchro-check relay. It lacked situational awareness of the phase angle difference. Yet, APS informed WECC RC and CAISO that it believed the line could be reclosed quickly, when, in fact, this could not have been done due to the phase angle difference.[104]

To avoid a similar situation in the future, TOPs should ensure that they have adequate tools to determine phase angles after the loss of transmission lines. For example, they can install PMUs throughout their system, as APS plans to do, to increase their situational awareness of phase angles. Moreover, TOPs should ensure that their operators are trained to respond to phase angle differences by, for example, redispatching generation. In addition, TOPs should not underestimate the time required to reclose a line, particularly without first knowing the phase angle difference. Here, for example, APS likely could not have reclosed the line quickly, even had it known the phase angle difference, given system conditions on the day of the event.

Indeed, the inquiry conducted a series of power flow simulations and found that significant amounts of generation redispatch were needed to close the phase angle difference. ***Figure* 17**, on the next page, shows the relationship between the voltage phase angle of H-NG as generation is redispatched between California and Arizona. The dispatched approach adjusts the available generation nearest the Hassayampa and North Gila buses. As generation is dispatched to its maximum output in the vicinity of the two

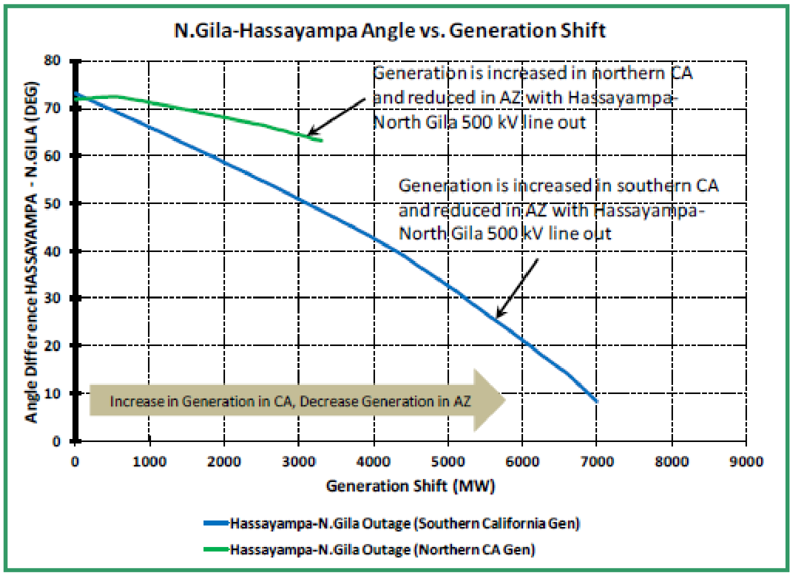
102 APS provides its certified operators with two training classes, Power System Dynamics and Dynamics of Disturbances, both of which address power angles and their ramifications. In addition, APS provides its new operator trainees with training on power angles.

103 APS plans to expand its use of PMUs to enable it to determine phase angle differences even without a line being energized. Through the PMU data, APS would be able to determine voltage and angle measurements on live buses in its substations, through which it could calculate phase angle differences.

104 APS did not intentionally mislead WECC RC and CAISO with this statement. Rather, it did not expect that there would have been such a large phase angle difference, as it had not previously experienced such a difference. Moreover, APS determined that the line was not damaged and, thus, it did not believe there would be any issues closing the line.

stations, other generators farther out are adjusted to effect the change in voltage phase angles.

Figure 17: Phase Angle of H-NG vs. Generation Shift



The blue line in Figure 17 illustrates that with the particular conditions of the September 8th event, approximately 1,800 MW needed to be redispatched on both ends of H-NG (and close to the terminals, in Southern California and Arizona) in order to close the voltage phase angle from 72 degrees to 60 degrees (i.e., to within the permissive 60 degree setting of the synchro-check relay). The green line shows that more generation—more than twice as much—must be redispatched if units are chosen in Northern California to close the angle between Hassayampa and North Gila.

While system operators could redispatch generation from available spinning reserves or commit units in the Southern and/or Northern California area, it is questionable how quickly 1,800 MW could be dispatched.

Appendix A: List of Acronyms Used in Report

ACE	Area Control Error
APS	Arizona Public Service
BA	Balancing Authority
BES	Bulk Electric System
BPS	Bulk-Power System
CAISO	California Independent System Operator, Inc.
CFE	Comisión Federal de Electricidad
CV	Coachella Valley
EMS	Energy Management System
GO	Generator Owner
GOP	Generator Operator
H-NG	APS's Hassayampa-North Gila 500 kV transmission line
IEEE	Institute of Electrical and Electronics Engineers
IID	Imperial Irrigation District
IROL	Interconnection Reliability Operating Limit
kV	Kilovolt
LAPS	Local Area Protection System
MVA	Megavolt-ampere
MW	Megawatt
NERC	North American Electric Reliability Corporation
OSS	California/Mexico Operations Study Subcommittee
OTC	Operating Transfer Capabilities
OTCPC	Operating Transfer Capability Policy Committee
PC	Planning Coordinator
PMU	Phasor Measurement Unit
RAS	Remedial Action Scheme
RC	Reliability Coordinator
RE	Regional Entity
RTCA	Real-Time Contingency Analysis
SASG	Southwest Area Study Group
SCADA	Supervisory Control and Data Acquisition
SCE	Southern California Edison
SDG&E	San Diego Gas & Electric
SE	State Estimator
SOE	Sequence of Events
SOL	System Operating Limit
SONGS	San Onofre Nuclear Generating Station
SPS	Special Protection System

WALC	Western Area Power Administration – Lower Colorado
WAPS	Wide Area Protection System
WECC	Western Electricity Coordinating Council
YCA	Yuma Cogeneration Associates

Appendix B: Table of Findings and Recommendations

The following table provides a complete list of findings and corresponding recommendations, each of which are discussed in detail at Section IV of the report.

NEXT-DAY PLANNING		
FINDING	**RECOMMENDATION**	**APPLICABLE ENTITIES**
Finding 1 – Failure to Conduct and Share Next-Day Studies: Not all of the affected TOPs conduct next-day studies or share them with their neighbors and WECC RC. As a result of failing to exchange studies, on September 8, 2011 TOPs were not alerted to contingencies on neighboring systems that could impact their internal system and the need to plan for such contingencies.	*Recommendation 1*: All TOPs should conduct next-day studies and share the results with neighboring TOPs and the RC (before the next day) to ensure that all contingencies that could impact the BPS are studied.	TOPs
Finding 2 – Lack of Updated External Networks in Next-Day Study Models: When conducting next-day studies, some affected TOPs use models for external networks that are not updated to reflect next-day operating conditions external to their systems, such as generation schedules and transmission outages. As a result, these TOPs' next-day studies do not adequately predict the impact of external contingencies on their systems or internal contingencies on external systems.	*Recommendation 2*: TOPs and BAs should ensure that their next-day studies are updated to reflect next-day operating conditions external to their systems, such as generation and transmission outages and scheduled interchanges, which can significantly impact the operation of their systems. TOPs and BAs should take the necessary steps, such as executing nondisclosure agreements, to allow the free exchange of next-day operations data between operating entities. Also, RCs should review the procedures in the region for coordinating next-day studies, ensure adequate data exchange among BAs and TOPs, and facilitate the next-day studies of BAs and TOPs.	TOPs, BAs, RCs
Finding 3 –Sub-100 kV Facilities Not Adequately Considered in Next-Day Studies: In conducting next-day studies, some affected TOPs focus primarily on the TOPs' internal SOLs and the need to stay within established Rated Path limits, without adequate consideration of some lower voltage facilities. As a result, these TOPs risk overlooking facilities that may become overloaded and impact the reliability of the BPS. Similarly,	*Recommendation 3*: TOPs and RCs should ensure that their next-day studies include all internal and external facilities (including those below 100 kV) that can impact BPS reliability.	TOPs, RCs

the RC does not study sub-100 kV facilities that impact BPS reliability unless it has specifically been alerted to issues with such facilities by individual TOPs or the RC has otherwise identified a particular sub-100 kV facility as affecting the BPS.		
Finding 4 – Flawed Process for Estimating Scheduled Interchanges: WECC RC's process for estimating scheduled interchanges is not adequate to ensure that such values are accurately reflected in its next-day studies. As a result, its next-day studies may not accurately predict actual power flows and contingency overloads.	*Recommendation 4*: WECC RC should improve its process for predicting interchanges in the day-ahead timeframe.	WECC RC
SEASONAL PLANNING		
FINDING	**RECOMMENDATION**	**APPLICABLE ENTITIES**
Finding 5 – Lack of Coordination in Seasonal Planning Process: The seasonal planning process in the WECC region lacks effective coordination. Specifically, the four WECC subregions do not adequately integrate and coordinate studies across the subregions, and no single entity is responsible for ensuring a thorough seasonal planning process. Instead of conducting a full contingency analysis based on all of the subregions' studies, the subregions rely on experience and engineering judgment in choosing which contingencies to discuss. As a result, individual TOPs may not identify contingencies in one subregion that may affect TOPs in the same or another subregion.	*Recommendation 5*: WECC RE should ensure better integration and coordination of the various subregions' seasonal studies for the entire WECC system. To ensure a thorough seasonal planning process, at a minimum, WECC RE should require a full contingency analysis of the entire WECC system, using one integrated seasonal study, and should identify and eliminate gaps between subregional studies. Individual TOPs should also conduct a full contingency analysis to identify contingencies outside their own systems that can impact the reliability of the BPS within their system and should share their seasonal studies with TOPs shown to affect or be affected by their contingencies.	WECC RE, TOPs
Finding 6 –External and Lower-Voltage Facilities Not Adequately Considered in Seasonal Planning Process: Seasonal planning studies do not adequately consider all facilities that may affect BPS reliability, including external facilities and lower-voltage facilities.	*Recommendation 6*: TOPs should expand the focus of their seasonal planning to include external facilities and internal and external sub-100 kV facilities that impact BPS reliability.	TOPs
Finding 7 – Failure to Study Multiple Load Levels: TOPs do	*Recommendation 7*: TOPs should expand the cases on which they run their individual	TOPs

not always run their individual seasonal planning studies based on the multiple WECC base cases (heavy and light load summer, heavy and light load winter, and heavy spring), but, instead, may focus on only one load level. As a result, contingencies that occur during the shoulder seasons (or other load levels not studied) might be missed.	planning studies to include multiple base cases, as well as generation maintenance outages and dispatch scenarios during high load shoulder periods.	
Finding 8 – Not Sharing Overload Relay Trip Settings: In the seasonal planning process, at least one TOP did not share with neighboring TOPs overload relay trip settings on transformers and transmission lines that impacted external BPS systems.	*Recommendation 8*: TOPs should include in the information they share during the seasonal planning process the overload relay trip settings on transformers and transmission lines that impact the BPS, and separately identify those that have overload trip settings below 150% of their normal rating, or below 115% of the highest emergency rating, whichever of these two values is greater.	TOPs
NEAR- AND LONG-TERM PLANNING		
FINDING	**RECOMMENDATION**	**APPLICABLE ENTITIES**
Finding 9 – Gaps in Near- and Long-Term Planning Process: Gaps exist in WECC RE's, TPs' and PCs' processes for conducting near- and long-term planning studies, resulting in a lack of consideration for: (1) critical system conditions; (2) the impact of elements operated at less than 100 kV on BPS reliability; and (3) the interaction of protection systems. As a consequence, the affected entities did not identify during the planning process that the loss of a single 500 kV transmission line could potentially cause cascading outages. Planning studies conducted between 2006 and 2011 should have identified the critical conditions that existed on September 8th and proposed appropriate mitigation strategies.	*Recommendation 9*: WECC RE should take actions to mitigate these and any other identified gaps in the procedures for conducting near- and long-term planning studies. The September 8th event and other major events should be used to identify shortcomings when developing valid cases over the planning horizon and to identify flaws in the existing planning structure. WECC RE should then propose changes to improve the performance of planning studies on a subregional- and Interconnection-wide basis and ensure a coordinated review of TPs' and PCs' studies. TOPs, TPs and PCs should develop study cases that cover critical system conditions over the planning horizon; consider the benefits and potential adverse effects of all protection systems, including RASs, Safety Nets (such as the SONGS separation scheme), and overload protection schemes; study the interaction of RASs and Safety Nets; and consider the impact of elements operated at less than 100 kV on BPS reliability.	WECC RE, TOPs, TPs, PCs
Finding 10 – Benchmarking WECC Dynamic Models: The inquiry obtained a very good correlation between the simulations and the actual event until the SONGS separation scheme activated. After	*Recommendation 10*: WECC dynamic models should be benchmarked by TPs against actual data from the September 8th event to improve their conformity to actual system performance. In particular, improvements to model performance from validation would be helpful in analysis of	TPs

activation of the scheme, however, neither the tripping of the SONGS units nor the system collapse of SDG&E and CFE could be detected using WECC dynamic models because some of the elements of the event are not explicitly included in those models. Sample simulations of the islanded region showed that by adding known details from the actual event, including UFLS programs and automatic capacitor switching, the simulation and event become more closely aligned following activation of the SONGS separation scheme.	under and/or over frequency events in the Western Interconnection and the stability of islanding scenarios in the SDG&E and CFE areas.	
SITUATIONAL AWARENESS		
FINDING	**RECOMMENDATION**	**APPLICABLE ENTITIES**
Finding 11 – Lack of Real-Time External Visibility: Affected TOPs have limited real-time visibility outside their systems, typically monitoring only one external bus. As a result, they lack adequate situational awareness of external contingencies that could impact their systems. They also may not fully understand how internal contingencies could affect SOLs in their neighbors' systems.	*Recommendation 11*: TOPs should engage in more real-time data sharing to increase their visibility and situational awareness of external contingencies that could impact the reliability of their systems. They should obtain sufficient data to monitor significant external facilities in real time, especially those that are known to have a direct bearing on the reliability of their system, and properly assess the impact of internal contingencies on the SOLs of other TOPs. In addition, TOPs should review their real-time monitoring tools, such as State Estimator and RTCA, to ensure that such tools represent critical facilities needed for the reliable operation of the BPS.	TOPs
Finding 12 – Inadequate Real-Time Tools: Affected TOPs' real-time tools are not adequate or, in one case, operational to provide the situational awareness necessary to identify contingencies and reliably operate their systems.	*Recommendation 12*: TOPs should take measures to ensure that their real-time tools are adequate, operational, and run frequently enough to provide their operators the situational awareness necessary to identify and plan for contingencies and reliably operate their systems.	TOPs
Finding 13 – Reliance on Post-Contingency Mitigation Plans: One affected TOP operated in an unsecured N-1 state on September 8, 2011, when it relied on post-contingency mitigation plans for its internal contingencies and subsequent overload and tripping, while assuming there would be	*Recommendation 13*: TOPs should review existing operating processes and procedures to ensure that post-contingency mitigation plans reflect the time necessary to take mitigating actions, including control actions, to return the system to a secure N-1 state as soon as possible but no longer than 30 minutes following a single contingency. As part of this review, TOPs should consider the effect of relays that automatically isolate	TOPs

sufficient time to mitigate the contingencies. Post-contingency mitigation plans are not viable under all circumstances, such as when equipment trips on overload relay protection that prevents operators from taking timely control actions. If this TOP had used pre-contingency measures on September 8th, such as dispatching additional generation, to mitigate first contingency emergency overloads for its internal contingencies, the cascading outages that were triggered by the loss of H-NG might have been avoided with the prevailing system conditions on September 8, 2011.	facilities without providing operators sufficient time to take mitigating measures.	
Finding 14 – WECC RC Staffing Concerns: WECC RC staffs a total of four operators at any one time to meet the functional requirements of an RC, including continuous monitoring, conducting studies, and giving directives. The September 8th event raises concerns that WECC RC's staffing is not adequate to respond to emergency conditions.	*Recommendation 14*: WECC RC should evaluate the effectiveness of its staffing level, training and tools. Based on the results of this evaluation, it should determine what actions are necessary to perform its functions appropriately as the RC and address any identified deficiencies.	WECC RC
Finding 15 – Failure to Notify WECC RC and Neighboring TOPs Upon Losing RTCA: On September 8, 2011, at least one affected TOP lost the ability to conduct RTCA more than 30 minutes prior to and throughout the course of the event due to the failure of its State Estimator to converge. The entity did not notify WECC RC or any of its neighboring TOPs, preventing this entity from regaining situational awareness.	*Recommendation 15*: TOPs should ensure procedures and training are in place to notify WECC RC and neighboring TOPs and BAs promptly after losing RTCA capabilities.	TOPs
Finding 16 – Discrepancies Between RTCA and Planning Models: WECC's model used by TOPs to conduct RTCA studies is not consistent with WECC's planning model and produces conflicting solutions.	*Recommendation 16*: WECC should ensure consistencies in model parameters between its planning model and its RTCA model and should review all model parameters on a consistent basis to make sure discrepancies do not occur.	WECC
CONSIDERATION OF BES EQUIPMENT		

FINDING	RECOMMENDATION	APPLICABLE ENTITIES
Finding 17 – Impact of Sub-100 kV Facilities on BPS Reliability: WECC RC and affected TOPs and BAs do not consistently recognize the adverse impact sub-100 kV facilities can have on BPS reliability. As a result, sub-100 kV facilities might not be designated as part of the BES, which can leave entities unable to address the reliability impact they can have in the planning and operations time horizons. If, prior to September 8, 2011, certain sub-100 kV facilities had been designated as part of the BES and, as a result, were incorporated into the TOPs' and RC's planning and operations studies, or otherwise had been incorporated into these studies, cascading outages may have been avoided on the day of the event.	*Recommendation 17*: WECC, as the RE should lead other entities, including TOPs and BAs, to ensure that all facilities that can adversely impact BPS reliability are either designated as part of the BES or otherwise incorporated into planning and operations studies and actively monitored and alarmed in RTCA systems.	WECC RE, TOPs, BAs
IROL DERIVATIONS		
FINDING	**RECOMMENDATION**	**APPLICABLE ENTITIES**
Finding 18 – Failure to Establish Valid SOLs and Identify IROLs: The cascading nature of the event that led to uncontrolled separation of San Diego, IID, Yuma, and CFE indicates that an IROL was violated on September 8, 2011, even though WECC RC did not recognize any IROLs in existence on that day. In addition, the established SOL of 2,200 MW on Path 44 and 1,800 MW on H-NG are invalid for the present infrastructure, as demonstrated by the event.	*Recommendation 18.1*: WECC RC should recognize that IROLs do exist on its system and, thus, should study IROLs in the day-ahead timeframe and monitor potential IROL exceedances in real-time. *Recommendation 18.2*: WECC RC should work with TOPs to consider whether any SOLs in the Western Interconnection constitute IROLs. As part of this effort, WECC RC should: (1) work with affected TOPs to consider whether Path 44 and H-NG should be recognized as IROLs; and (2) validate existing SOLs, and ensure that they take into account all transmission and generation facilities and protection systems that impact BPS reliability.	WECC RC, TOPs
PROTECTION SYSTEMS		
FINDING	**RECOMMENDATION**	**APPLICABLE ENTITIES**
Finding 19 – Lack of Coordination of the S Line RAS: Several TOs and TOPs did not properly coordinate a RAS by: (1)	*Recommendation 19*: The TOs and TOPs responsible for design and coordination of the S Line RAS should revisit its design basis and protection settings to ensure	TOs, TOPs

not performing coordination studies with the overload protection schemes on the facilities that the S Line RAS is designed to protect; and (2) not assessing the impact of setting relays to trip generation sources and a 230 kV transmission tie line prior to the operation of a single 161/92 kV transformer's overload protection. As a result, BES facilities were isolated in excess of those needed to maintain reliability, with adverse impact on BPS reliability.	coordination with other protection systems in order to prevent adverse impact to the BPS, premature operation, and excessive isolation of facilities. TOs and TOPs should share any changes to the S Line RAS with TPs and PCs so that they can accurately reflect the S Line RAS when planning.	
Finding 20 – Lack of Coordination of the SONGS Separation Scheme: SCE did not coordinate the SONGS separation scheme with other protection systems, including protection and turbine control systems on the two SONGS generators. As a result, SCE did not realize that Units 2 and 3 at SONGS would trip after operation of the separation scheme.	*Recommendation 20*: SCE should ensure that the SONGS separation scheme is coordinated with other protection schemes, such as the generation protection and turbine control systems on the units at SONGS and UFLS schemes.	SCE
Finding 21 – Effect of SONGS Separation Scheme on SONGS Units: The SONGS units tripped due to their turbine control systems detecting unacceptable acceleration following operation of the SONGS separation scheme.	*Recommendation 21*: GOs and GOPs should evaluate the sensitivity of the acceleration control functions in turbine control systems to verify that transient perturbations or fault conditions in the transmission system resulting in unit acceleration will not result in unit trip without allowing time for protective devices to clear the fault on the transmission system.	GOs, GOPs
Finding 22 – Lack of Review and Studying Impact of SPSs: Although WECC equates SPSs with RASs, prior to October 1, 2011, WECC's definition of RAS excluded many protection systems that would be included within NERC's definition of SPS. As a result, WECC did not review and assess all NERC-defined SPSs in its region, and WECC's TOPs did not perform the required review and assessment of all NERC-defined SPSs in their areas.	*Recommendation 22*: WECC RE, along with TOs, GOs, and Distribution Providers (DPs), should periodically review the purpose and impact of RASs, including Safety Nets and Local Area Protection Schemes, to ensure they are properly classified, are still necessary, serve their intended purposes, are coordinated properly with other protection systems, and do not have unintended consequences on reliability. WECC RE and the appropriate TOPs should promptly conduct these reviews for the SONGS separation scheme and the S Line RAS.	WECC RE, TOs, GOs, DPs, TOPs

Finding 23 – Effect of Inadvertent Operation of SONGS Separation Scheme on BPS Reliability: The inquiry's simulation of the event shows that the inadvertent operation of the SONGS separation scheme under normal system operations could lead to a voltage collapse and blackout in the SDG&E areas under certain high load conditions.	*Recommendation 23*: CAISO and SCE should promptly verify that the inadvertent operation of the SONGS separation scheme does not pose an unacceptable risk to BPS reliability. Until this verification can be completed, they should consider all actions to minimize this risk, up to and including, temporarily removing the SONGS separation scheme from service.	CAISO, SCE
Finding 24 – Not Recognizing Relay Settings When Establishing SOLs: An affected TO did not properly establish the SOL for two transformers, as the SOL did not recognize that the most limiting elements (protective relays) were set to trip below the established emergency rating. As a result, the transformers tripped prior to the facilities being loaded to their emergency ratings during the restoration process, which delayed the restoration of power to the Yuma load pocket.	*Recommendation 24*: TOs should reevaluate their facility ratings methodologies and implementation of the methodologies to ensure that their ratings are equal to the most limiting piece of equipment, including relay settings. No relay settings should be set below a facility's emergency rating. When the relay setting is determined to be the most limiting piece of equipment, consideration should be given to reviewing the setting to ensure that it does not unnecessarily restrict the transmission loadability.	TOs
Finding 25 – Margin Between Overload Relay Protection Settings and Emergency Rating: Some affected TOs set overload relay protection settings on transformers just above the transformers' emergency rating, resulting in facilities being automatically removed from service before TOPs have sufficient time to take control actions to mitigate the resulting overloads. One TO in particular set its transformers' overload protection schemes with such narrow margins between the emergency ratings and the relay trip settings that the protective relays tripped the transformers following an N-1 contingency.	*Recommendation 25*: TOs should review their transformers' overload protection relay settings with their TOPs to ensure appropriate margins between relay settings and emergency ratings developed by TOPs. For example, TOs could consider using the settings of Reliability Standard PRC-023-1 R.1.11 even for those transformers not classified as BES. PRC-023-1 R.1.11 requires relays to be set to allow the transformer to be operated at an overload level of at least 150% of the maximum applicable nameplate rating, or 115% of the highest operator established emergency transformer rating, whichever is greater.	TOs, TOPs
Finding 26 –Relay Settings and Proximity to Emergency Ratings: Some TOs set relays to isolate facilities for loading conditions slightly above their thirty minute emergency ratings. As a result, several transmission lines and transformers tripped	*Recommendation 26*: TOs should evaluate load responsive relays on transmission lines and transformers to determine if the settings can be raised to provide more time for TOPs to take manual action to mitigate overloads that are within the short-time thermal capability of the equipment instead of allowing relays to prematurely isolate the	TOs, TOPs

within seconds of exceeding their emergency ratings, leaving TOPs insufficient time to mitigate overloads.	transmission lines. If the settings cannot be raised to allow more time for TOPs to take manual action, TOPs must ensure that the settings are taken into account in developing facility ratings and that automatic isolation does not result in cascading outages.	

ANGULAR SEPARATION		
FINDING	**RECOMMENDATION**	**APPLICABLE ENTITIES**
Finding 27 – Phase Angle Difference Following Loss of Transmission Line: A TOP did not have tools in place to determine the phase angle difference between the two terminals of its 500 kV line after the line tripped. Yet, it informed the RC and another TOP that the line would be restored quickly, when, in fact, this could not have been accomplished.	*Recommendation 27*: TOPs should have: (1) the tools necessary to determine phase angle differences following the loss of lines; and (2) mitigation and operating plans for reclosing lines with large phase angle differences. TOPs should also train operators to effectively respond to phase angle differences. These plans should be developed based on the seasonal and next-day contingency analyses that address the angular differences across opened system elements.	TOPs

Appendix C: Comparison of August 2003 and September 2011 Blackouts

On August 14, 2003, an estimated 50 million people throughout the Midwest and Northeast United States and Ontario, Canada, experienced an electric power blackout. A day later, the joint U.S.-Canada Power System Outage Task Force began investigating the causes of the blackout and considering ways to prevent such outages in the future. The task force detailed its findings and recommendations in an April 2004 report.[105] A comparison of the findings and recommendations in this April 2004 report and the instant report on the September 8, 2011, blackout reveals commonalities between the two events.

Although the August 2003 and September 2011 blackouts were triggered by different initiating events—tree touches in 2003 compared to a switching error in 2011—both blackouts had common underlying causes. First, affected entities in both events did not conduct adequate long-term and operations planning studies necessary to understand vulnerabilities on their systems. Second, affected entities in both events had inadequate situational awareness leading up to and during the disturbances. In addition to these two underlying causes, both events were exacerbated by protection system relays that tripped facilities without allowing operators sufficient time to take mitigating measures. These similarities are highlighted below, with excerpts from both reports to illustrate specific comparisons.

Inadequate Long-Term and Operations Planning

The 2003 Blackout Report states that "FirstEnergy was not [operating its system securely] because the company had not conducted the long-term and operational planning studies needed to understand [certain] vulnerabilities and their operational implications."[106] Similarly, this inquiry's report found that several entities' operational and long-term studies did not adequately ensure the reliable operation of their systems. Specifically, both reports described relevant planning studies that: (1) did not adequately identify and study critical external facilities; (2) did not adequately analyze potential contingency scenarios; and (3) were based on inaccurate models and invalid system operating limits (SOLs).

105 Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations (U.S.-Canada Power System Outage Task Force: April 2004) (2003 Blackout Report).

106 2003 Blackout Report at 23.

Inadequate Long Term and Operations Planning

Issue	2003 Blackout	2011 Blackout
Insufficient Analysis in Seasonal Studies	"[T]he studies FirstEnergy relied on . . . were not robust, thorough, or up-to-date. This left FE's planners and operators with a deficient understanding of their system's capabilities and risks under a range of system conditions." (P. 39). "FE's 2003 Summer Study focused primarily on single-contingency (N-1) events, and did not consider significant multiple contingency losses and security. . . . Overall, the summer study posited less stressful system conditions than actually occurred August 14, 2003 (when load was well below historic peak demand)." (P 39).	"TOPs do not always run their individual seasonal planning studies based on the multiple WECC base cases (heavy and light load summer, heavy and light load winter, and heavy spring), but, instead, may focus on only one load level." (Finding 7) "Seasonal planning studies do not adequately consider all facilities that may affect BPS reliability, including external facilities and lower-voltage facilities."(Finding 6) "In the seasonal planning process, at least one TOP did not share with neighboring TOPs overload relay trip settings on transformers and transmission lines that impacted external BPS systems." (Finding 8)
Inadequate Identification and Study of Critical External Facilities	"On August 14 four or five capacitor banks within the Cleveland-Akron area had been removed from service for routine inspection. . . . These static reactive power sources are important for voltage support. . . . The unavailability of the critical reactive resources was not known to those outside of FirstEnergy." (PP. 26-27). "NERC policy requires that critical facilities be identified and that neighboring control areas and reliability coordinators be made aware of the status of those facilities to identify the impact of those conditions on their own facilities. However, FE never identified these capacitor banks as critical and so did not pass on status information to others." (P. 27).	"Not all of the affected TOPs conduct next-day studies or share them with their neighbors and WECC RC. . . .TOPs were not alerted to contingencies on neighboring systems that could impact their internal system and the need to plan for such contingencies." (Finding 1) "In conducting next-day studies, some affected TOPs focus primarily on the TOPs' internal SOLs and the need to stay within established Rated Path limits, without adequate consideration of some lower voltage facilities." (Finding 3) "[In conducting next-day studies,] . . . the RC does not study sub-100 kV facilities that impact BPS reliability unless it has specifically been alerted to issues with such facilities by individual TOPs..." (Finding 3)

Inaccurate Dynamic Models	"The after-the-fact models developed to simulate August 14 conditions and events found that the dynamic modeling assumptions for generator and load power factors in regional planning and operating models were frequently inaccurate." (P. 160).	". . . neither the tripping of the SONGS units nor the system collapse of SDG&E and CFE could be detected using WECC dynamic models because some of the elements of the event are not explicitly included in those models." (Finding 10)

To mitigate these concerns, the 2003 Blackout Report recommended that "NERC should work with the regional reliability councils to establish regional power system models that enable the sharing of consistent and validated data among entities in the region,"[107] and "[c]larify criteria for identification of operationally critical facilities, and improve dissemination of updated information on unplanned outages."[108] This inquiry's report likewise recommends that entities cooperate and coordinate more effectively across all planning horizons, especially by increasing visibility in both external systems and lower voltage facilities that could impact BPS reliability.

Inadequate Situational Awareness

The 2003 Blackout Report stated, "A principal cause of the August 14 blackout was a lack of situational awareness, which was in turn the result of inadequate reliability tools and backup capabilities."[109] Similarly, the instant inquiry determined that inadequate real-time situational awareness contributed to the cascading outages. In both events, for example, the affected entities' real-time monitoring tools were not adequate to alert operators to system conditions and contingencies. Also, some of the affected entities in both events did not use their real-time tools to monitor system conditions. As a result of these situational awareness issues, affected entities in both events were not aware that they were no longer operating in a secure N-1 state and were not alerted to the need to take corrective actions.

Inadequate Situational Awareness		
Issue	2003 Blackout	2011 Blackout
System Visibility	"MISO [the Reliability Coordinator] had interpretive and operational tools and a large amount of system data, but had a limited view of FE's system." (P. 67).	"Affected TOPs have limited real-time visibility outside their systems, typically monitoring only one external bus. As a result, they lack adequate situational awareness of external contingencies that could impact

[107] 2003 Blackout Report at 160.

[108] 2003 Blackout Report at 3.

[109] 2003 Blackout Report at 159.

Inadequate Situational Awareness		
Issue	2003 Blackout	2011 Blackout
		their systems. They also may not fully understand how internal contingencies could affect SOLs in their neighbors' systems." (Finding 11)
Inadequate Real-Time Monitoring Tools	"FE's operational monitoring equipment was not adequate to alert FE's operators regarding important deviations in operating conditions and the need for corrective action." (P. 19). "FE's control room operators lost the alarm function that provided audible and visual indications when a significant piece of equipment changed from an acceptable to a problematic condition." (P. 51). MISO's incomplete tool set and the failure to supply its state estimator with correct system data on August 14 contributed to the lack of situational awareness." (P. 159).	"Affected TOPs' real-time tools are not adequate or, in one case, operational to provide the situational awareness necessary to identify contingencies and reliably operate their systems." (Finding 12) ". . . a TOP lost the ability to conduct [Real Time Contingency Analysis] RTCA more than 30 minutes prior to and throughout the course of the event ...[and] did not notify WECC RC or any of its neighboring TOPs..."(Finding 15)
Operating in an Unsecure State	"FE's operators were not aware that the system was operating outside first contingency limits . . . because they did not conduct a contingency analysis." (P. 64). "MISO's reliability coordinators were using non-real-time data to support real-time "flowgate" monitoring. This prevented MISO from detecting an N-1 security violation in FE's system and from assisting FE in necessary relief actions." (P. 19). "Since FE's operators were not aware and did not recognize events as they were occurring, they took no actions to return the system to a reliable state." (P. 65).	"The cascading nature of the event that led to uncontrolled separation of San Diego, IID, Yuma, and CFE indicates that an [interconnection reliability operating limit] IROL was violated . . . In addition, the established SOLs of 2,200 MW on Path 44 and 1,800 MW on H-NG are invalid..."(Finding 18) "One affected TOP operated in an unsecured N-1 state. . . . when it relied on post-contingency mitigation plans for its internal contingencies and subsequent overloads and trips, while assuming there would be sufficient time to mitigate the contingencies." (Finding 13)

To remedy these weaknesses in situational awareness, the 2003 Blackout Report recommended that entities [e]valuate and adopt better real-time tools for operators and reliability coordinators."[110] Similarly, this inquiry's report recommends that operators develop and effectively utilize the real-time tools at their disposal and include all facilities that can impact BPS reliability.

Protection Systems

During both events, protection system settings exacerbated and accelerated the cascading nature of the outages. As stated in the 2003 Blackout Report, zone 3 relay settings "did not cause the blackout, [but] it is certain that they greatly expanded and accelerated the spread of the cascade."[111] Similarly, load responsive relay settings accelerated the September 8th cascade and effectively eliminated the window in which operators could have taken mitigating actions.

Protection Systems		
Issue	**2003 Blackout**	**2011 Blackout**
Overly Conservative Relay Protection Settings	"A few lines have zone 3 settings designed with overload margins close to the long-term emergency limit of the line. . . .Thus, it is possible for a zone 3 relay to operate on line load or overload in extreme contingency conditions even in the absence of a fault." (P. 80)	"Some affected TOs set overload relay protection settings on transformers just above the transformers' emergency rating, resulting in facilities being automatically removed from service before TOPs have sufficient time to take control actions . . . following an N-1 contingency." (Finding 25)
Cascading Relay Overload Trips	"[B]ecause these zone 2 and 3 relays tripped after each line overloaded, these relays were the common mode of failure that accelerated the geographic spread of the cascade." (P. 80)	"Some TOs set relays to isolate facilities for loading conditions slightly above their thirty minute emergency ratings. As a result, several transmission lines and transformers tripped within seconds of exceeding their emergency ratings, leaving TOPs insufficient time to mitigate overloads." (Finding 26)
Relay Protection Acting Too Quickly to Allow System Operators to Take Action	"[T]he speed of the zone 2 and 3 operations across Ohio and Michigan eliminated any possibility . . . that either operator action or automatic intervention could have limited or mitigated the growing cascade." (P. 80).	"Some affected TOs set overload relay protection settings on transformers just above the transformers' emergency rating, resulting in facilities being automatically removed from service before TOPs have

[110] 2003 Blackout Report at 159.

[111] 2003 Blackout Report at 82. Zone 3 relays "provide breaker failure and relay backup for remote distance faults on a transmission line." *Id.* at 80.

Protection Systems		
Issue	**2003 Blackout**	**2011 Blackout**
		sufficient time to take control actions...” (Finding 25) “. . . several transmission lines and transformers tripped within seconds of exceeding their emergency ratings, leaving TOPs insufficient time to mitigate overloads. (Finding 26)

After seeing the consequences of conservative zone 3 settings, the 2003 Blackout Report recommended that “[i]ndustry is to review zone 3 relays on lines of 230 kV and higher.”[112] This inquiry’s report similarly recommends that Transmission Owners review their facilities’ overload relay protection settings to ensure the appropriate margin between relay settings and emergency ratings.

[112] 2003 Blackout Report at 158.

Appendix D: Benchmarking the Model

I. Introduction and Background

The inquiry's Modeling and Simulation Team replicated system conditions on September 8, 2011, and the events leading up to the blackout. The model reflects the state of the electric system before and during the event, with the real power output of generators dispatched to the values recorded in SCADA data. With any major event on the BPS, it is important to accurately model the system before and during the event in order to: (1) verify the Sequence of Events; (2) support reconciliation of disparate measurement data; and (3) simulate and evaluate hypothetical scenarios, or "what-if" scenarios.

In order to ensure the accuracy of these tasks, the Modeling and Simulation Team benchmarked the model to recorded SCADA and PMU measurements using the following guidelines. Key facilities and interfaces in the affected area were generally benchmarked to within 5% or 10 MVA accuracy to the measured data. Generator reactive outputs were also checked against recorded values to ensure that the representation of reactive power margin was reasonably accurate. The team also monitored most other facilities in the affected area to ensure that the flows and voltage were reasonably close to measured data. Many of these other facilities also met the same guidelines used to benchmark the key facilities and interfaces.

The iterative process between benchmarking and case alteration has traditionally been time-consuming. The team pursued methods that would ultimately decrease the amount of time spent benchmarking so that results could quickly be used to identify problem areas in the case and make appropriate adjustments. Because the team received SCADA and PMU measurement data from many sources and entities, the data was: (1) organized into a consistent format, useful for automated benchmarking; and (2) cross-checked and verified for accuracy. In organizing the data, the team also considered how each data point would map back to both power flow and dynamics results. The team ultimately achieved a single process to: (1) import power flow results; (2) import dynamics results; (3) compare the results to measured data from many sources at various quasi-steady state times during the event; (4) export tables showing the percentage accuracy; and (5) export graphs showing the accuracy of the results relative to measured data throughout the event.

II. Discussion

The locations and measurements that the team selected for benchmarking were naturally predicated on the available measurements. While the team compared each available data point to the model results, it did not benchmark the model to all available data points. Instead the team focused its benchmarking effort on a "study area" that included SDG&E, IID, the APS Yuma load pocket, and portions of CFE and SCE. The team gave preference to measurements that were available in multiple data sources with some reasonable agreement between the different sources, and particular preference to those locations where PMU measurements were available, because these measurements could also be benchmarked against a full dynamics simulation.

Following each set of simulations, the team reviewed the benchmarking data both graphically and tabularly, and tuned the modeling case and simulation parameters in an attempt to bring the case closer to measured reality. The team would then re-run the simulation, and repeat this process.

Custom Interfaces

Even though the team selected the best possible set of benchmarking data, and a substantial amount of work went into calibrating the study area of the modeling case to those measurements, inconsistencies between some data points persisted. These inconsistencies arose due to the multitude of subtle settings and parameters for equipment, such as a changed tap on a single transformer affecting reactive power flow. For this reason, the team developed "custom interfaces" to benchmark an aggregation of points. If an aggregated, modeled sub-system was very close to the actual measurements for that system, then the simulation could be trusted to accurately reflect the system. For example, if reactive power flow was misallocated to a pair of adjacent transformers sourcing a sub-system, the specific reactive flow on each transformer may not be of particular importance to the model. However, the reactive flow to the aggregate load being served by those transformers may have a significant impact on a neighboring sub-system, and be crucial to effective benchmarking.

The custom interfaces were also defined so as to indicate the amount of flow into or across a particular sub-system. For example, the calculated flows at the "IID North 92 kV System" interface give an idea of the amount and nature of the load in the northern IID 92 kV system. The custom interfaces selected include:

- **IID North 92 kV System:** All transmission sources for the northern IID 92 kV system, including the 230/92 kV transformers at Coachella Valley and Ramon, the 161/92 kV transformers at Coachella Valley and Avenue 58, and the 92 kV lines between the northern and southern IID systems.

- **IID South 92 kV System:** All transmission sources for the southern IID 92 kV system, including the 230 kV transformer at El Centro, the 161/92 kV transformers at El Centro and Niland, and the 92 kV lines between the southern and northern IID systems.
- **Yuma Pocket:** Interfaces between the Yuma area 69 kV system (including portions of both APS and WALC service territories) and higher-voltage systems, including the 500/69 kV transformers at N. Gila, the 161/69 kV transformers at Gila, and the 161 kV line from Pilot Knob to Yucca.
- **Southwest California Desert Imports:** All transmission sources into the IID/SDG&E/CFE/Yuma area other than Path 44.

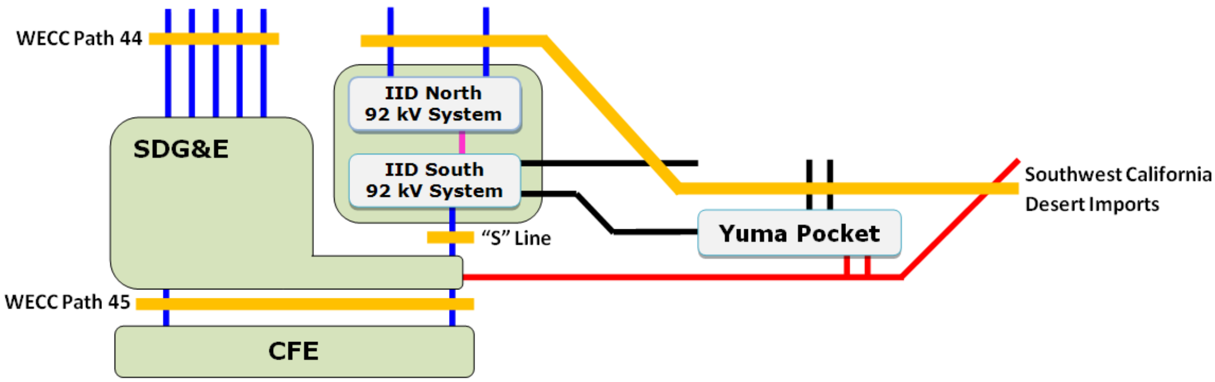

Figure 1: Key Facilities and Interfaces

Key Facilities and Interfaces

The team chose key facilities and interfaces in the affected area as a way to quickly evaluate the model before fine-tuning it on a more granular level. These key facilities and interfaces were benchmarked to within 5% or 10 MVA accuracy to the measured data throughout the entire event. The key facilities and interfaces are listed below.

- WECC Path 44
- Southwest California Desert Imports
- IID Northern 92 kV System
- Niland-Blythe 161 kV Transmission Line
- IID Southern 92 kV System
- Imperial Valley-El Centro 230 kV Transmission Line ("S" Line)
- Miguel-Imperial Valley 500 kV Transmission Line
- Yuma Pocket
- El Centro-Pilot Knob 161 kV Transmission Line
- Pilot Knob-Knob 161 kV Transmission Line
- Pilot Knob-Yucca 161 kV Transmission Line
- Julian Hinds-Mirage 230 kV Transmission Line
- Julian Hinds-Eagle Mountain 230 kV Transmission Line

III. Results

The following graphs demonstrate the benchmarking results. Each plot gives both power flow (see "TSS" in graph legend)[113] and dynamic simulation (see "DYD" in graph legend)[114] results at each selected time step, with the corresponding SCADA and/or PMU measurement, as available. In some instances, known issues with measured data are annotated on the charts, such as SCADA measurement errors for Coachella Valley during the interval following the initiating event.

The simulated MW values follow the measurements more closely than the simulated MVAR values. This is due to complexity involved in tuning voltage at each bus due to incomplete data, such as unknown tap values on large transformers. Overall, the MVA values are within our benchmarking guidelines.

The team also provided a table that compares: (1) the base case at 15:27:00 to the measured data; and (2) the case just prior to the loss of the Coachella Valley transformers at 15:28:11 to the measured data. This table does not compare the dynamics values to the base case at 15:27:00 because the power flow base case was the foundation for the dynamics simulation, meaning the values would be equal.

115 Large differences due to SCADA measurement errors at Coachella Valley and Ramon

116 Id.

117 The team experienced difficulty in calibrating the MVAR flows in this area, but are generally confident in the benchmarking because the MW values are within 10 MW. The MVA differences in the model appear to increase during this event. The representation of the system in this area of the model appears to assume that the IID South 92 kV system is a load serving local network. However, the actual transmission system operates in parallel with the rest of the BPS. It was difficult to calibrate the flows at the 92 kV to 161 kV interfaces because of the differences between the representation of the system in the model versus the parallel nature of the actual system.

Summary of Development and Complete Record of Development

Summary of Development

Summary of Development History

The development record for proposed Reliability Standards IRO-018-1 and IRO-010-1 is summarized below.

I. Overview of the Standard Drafting Team

When evaluating a proposed Reliability Standard, the Commission is expected to give "due weight" to the technical expertise of the ERO.[1] The technical expertise of the ERO is derived from the standard drafting team selected to lead each project in accordance with Section 4.3 of the NERC Standards Process Manual.[2] For this project, the standard drafting team consisted of industry experts, all with a diverse set of experiences. A roster of the standard drafting team members is included in Exhibit I.

II. Standard Development History

A. Standard Authorization Request Development

In April 2015, the Standards Committee (SC) appointed a new Standard Authorization Request (SAR) Drafting Team (DT) to resume development on Project 2009-02 Real-time Monitoring and Analysis Capabilities. This project originated in 2009 in response to work done by the NERC Operating Committee's Real-time Tools Best Practices Task Force (RTBP Task Force) but was paused in 2011. In determining the recommended scope for standards development, the SAR DT reviewed previous work associated with this project along with recommendations from the 2008 RTBP Task Force report, FERC Order No. 693 directives, and recommendations from the 2011 Southwest Outage Report. Additionally, an industry technical conference was conducted on June 4, 2015, to solicit feedback and recommendations from

---

1 Section 215(d)(2) of the Federal Power Act; 16 U.S.C. §824(d) (2) (2012).

2 The NERC *Standard Processes Manual* is available at http://www.nerc.com/comm/SC/Documents/Appendix_3A_StandardsProcessesManual.pdf.

industry stakeholders. A SAR for Project 2009-02 was submitted in June 18, 2015. The SAR and a supporting white paper were posted for 30-day formal comment from July 16, 2015 through August 17, 2015. The SC accepted the SAR on September 23, 2015.

B. First Posting - Comment Period, Initial Ballot and Non-Binding Poll

Proposed Reliability Standards IRO-018-1 and TOP-010-1 were posted for a 45-day formal comment period from September 24, 2015 through November 9, 2015, with parallel initial ballots and non-binding polls held during the last 10 days of the comment period from October 30, 2015 through November 9, 2015. Several documents were posted for guidance with the first draft, including the Unofficial Comment Form, the SAR, the SAR Justification White Paper, the Violation Risk Factors (VRFs) and Violation Severity Levels (VSLs) Justification document, and the Consideration of Directives document. The initial ballot for IRO-018-1 received 84.59% quorum, and 47.36% approval. The initial ballot for TOP-010-1 received 84.49% quorum, and 48.01% approval. The Non-Binding Poll for IRO-018-1 received 82.71% quorum and 54.61% of supportive opinions. The Non-Binding Poll for TOP-010-1 received 83.94% quorum and 56.25% of supportive opinions. There were 42 sets of responses, including comments from approximately 133 different individuals and approximately 102 companies, representing 8 of the 10 industry segments.[3]

C. Second Posting- Comment Period, Additional Ballots and Non-Binding Polls

Proposed Reliability Standards IRO-018-1 and TOP-010-1 were posted for a 45-day formal comment period from December 10, 2015 through January 26, 2016, with parallel additional ballots and nonbinding polls held during the last 10 days of the comment period from

---

[3] NERC, *Consideration of Comments*, Project 2009-02, (December 8, 2015), *available at* http://www.nerc.com/pa/Stand/Project%20200902%20Rela%20Time%20Monitotring%20Analysis%20Capa/2009-02_RTMAC_Consideration_of_comments_120815.pdf.

January 15, 2016 through January 26, 2016.[4] The additional ballot for IRO-018-1 reached quorum at 82.88% of the ballot pool, and received 72.14% approval. The additional ballot for TOP-010-1 reached quorum at 82.18% of the ballot pool, and received 68.01% approval. The related Non-Binding Poll for IRO-018-1 reached quorum 81.95% of the ballot pool, and 81.76% of supportive opinions. The related Non-Binding Poll for TOP-010-1 reached quorum 81.02% of the ballot pool, with 76.27% of supportive opinions. There were 38 sets of responses, including comments from approximately 93 different individuals and approximately 69 companies, representing 7 of the 10 industry segments.[5]

D. Final Ballot

Proposed Reliability Standards IRO-018-1 and TOP-010-1 were posted for a 10-final ballot period from February 17, 2016 through February 26, 2016. The ballot for the proposed Reliability Standard IRO-018-1 and associated documents reached quorum at 88.36% of the ballot pool, and the standard received sufficient affirmative votes for approval, receiving support from 75.68% of the voters. The ballot for the proposed Reliability Standard TOP-010-1 and associated documents reached quorum at 87.79% of the ballot pool, and the standard received sufficient affirmative votes for approval, receiving support from 73.86% of the voters.

E. Board of Trustees Adoption

Proposed Reliability Standards IRO-018-1 and TOP-010-1 were adopted by the NERC Board of Trustees on May 5, 2016.

---

4 The ballots and non-binding polls were extended an additional day from January 25, 2016 to reach quorum.

5 NERC, *Consideration of Comments*, Project 2009-02, (February 17, 2016), *available at* http://www.nerc.com/pa/Stand/Project%20200902%20Rela%20Time%20Monitotring%20Analysis%20Capa/Consideration_of_Comments_Feb_12_rev.pdf.

Complete Record of Development History

Project 2009-02 Real-time Reliability Monitoring and Analysis Capabilities

Related Files

Status

Final ballots for **IRO-018-1 - Reliability Coordinator Real-time Monitoring and Analysis Capabilities** and **TOP-010-1 - Real-time Reliability Monitoring and Analysis Capabilities** concluded **8 p.m. Eastern, Friday, February 26, 2016**. The voting results can be accessed via the links below. The standards will be submitted to the Board of Trustees for adoption and then filed with the appropriate regulatory authorities.

Background

Project 2009-02 is included in the 2015-2017 Reliability Standards Development Plan (RSDP) approved by the NERC Board of Trustees (Board) on November 13, 2014. Formal development of this project was paused in 2011 and has resumed to address outstanding Federal Energy Regulatory Commission (FERC) directives and issues that were not consolidated into Project 2014-03 TOP/IRO Revisions.

Project 2009-02 was initiated in response to work done by the NERC Operating Committee's Real-time Tools Best Practices Task Force (RTBPTF). From 2009 to 2011, a SAR drafting team developed a SAR and technical white paper to establish requirements for the "functionality, performance, and maintenance of Real-time Monitoring and Analysis Capabilities." Since that time, new TOP and IRO standards have been developed that affect the scope of Project 2009-02.

Standard(s) Affected - Two new standards are being proposed: IRO-018-1 - Reliability Coordinator Real-time Monitoring and Analysis Capabilities and TOP-010-1 - Real-time Reliability Monitoring and Analysis Capabilities.

Purpose/Industry Need

The proposed standards will establish requirements for Real-time monitoring and analysis capabilities used by System Operators in support of reliable System operations. The SAR addresses selected recommendations in the RTBPTF Report www.nerc.com/comm/OC/Pages/RTBPTF/Real-time-Tools-Best-Practices-Task-Force.aspx, Federal Energy Regulatory Commission (FERC) Order 693 directives, and Bulk Electric System event reports as explained in the SAR Justification White Paper available at the link in the table below.

Unofficial Nomination Form for Real-time Tools SAR Drafting Team (Project 2009-02)

Please use the electronic nomination form located at the link below to submit your nomination by **June 25, 2009** to participate on the SAR Drafting Team. If you have any questions, please contact David Taylor at david.taylor@nerc.net.

http://www.nerc.com/filez/standards/Project2009-02_Real_Time_Tools.html

By submitting the following information you are indicating your willingness and agreement to actively participate in the SAR development process and SAR Drafting Team meetings if appointed to the SAR Drafting Team by the Standards Committee.

Name:	
Organization:	
Address:	
Telephone:	
E-mail:	

Project 2009-02 Real Time Tools - The SAR calls for developing a new standard or standards to establish requirements for the functionality, performance, and management of Real-time tools for Reliability Coordinators, Transmission Operators, and Balancing Authorities for use by their System Operators in support of reliable System operations.

Please briefly describe your experience and qualifications directly related to the issues to be addressed by the Real-time Tools SAR Drafting Team. We are seeking a cross section of the industry to participate on the team, but in particular are seeking individuals who collectively have experience in real time operations and knowledge of supervisory control and data acquisition (SCADA) and energy management system (EMS) applications used to support real time operations. Experience in developing would be beneficial as the team will be assisting the requester in exploring the gray area between “what” and “how” in this SAR.

Are you currently a member of any NERC or Regional Entity SAR or standard drafting team? If yes, please list each team here.

☐ No

☐ Yes:

Have you previously worked on any NERC or Regional Entity SAR or standard drafting teams? If yes, please list them here. ☐ No ☐ Yes:
Please identify the NERC Reliability Region(s) in which your company operates and for which you are able to represent your company's position relative to the applicable issues while serving on the SAR drafting team:

☐ ERCOT ☐ FRCC	☐ MRO ☐ NPCC	☐ RFC ☐ SERC	☐ SPP ☐ WEC

☐ Not Applicable or None of the Above

Please identify the Industry Segment(s) for which you are able to represent on behalf of your company while serving on the SAR drafting team:

☐	1 — Transmission Owners
☐	2 — RTOs and ISOs
☐	3 — Load-serving Entities
☐	4 — Transmission-dependent Utilities
☐	5 — Electric Generators
☐	6 — Electricity Brokers, Aggregators, and Marketers
☐	7 — Large Electricity End Users
☐	8 — Small Electricity End Users
☐	9 — Federal, State, and Provincial Regulatory or other Government Entities
☐	10 — Regional Reliability Organizations and Regional Entities
☐	Not applicable

Which of the following Functional Entities[1] do you have expertise or responsibilities for which you are able to represent on behalf of your company while serving on the SAR drafting team:

[1] These functions are defined in the NERC Functional Model, which is available on the NERC Web site.

☐ Balancing Authority	☐ Planning Coordinator
☐ Compliance Enforcement Authority	☐ Transmission Operator
☐ Distribution Provider	☐ Transmission Owner
☐ Generator Operator	☐ Transmission Planner
☐ Generator Owner	☐ Transmission Service Provider
☐ Interchange Authority	☐ Purchasing-selling Entity
☐ Load-serving Entity	☐ Resource Planner
☐ Market Operator	☐ Reliability Coordinator

Please provide the names and contact information for two references who could attest to your technical qualifications and your ability to work well in a group which you give us permission to contact in the event it is deemed necessary to do so.

Standards Announcement

Nomination Period Opens for Standard Authorization Request (SAR) Drafting Team
June 9–25, 2009

Now available at: http://www.nerc.com/filez/standards/Project2009-02_Real_Time_Tools.html

Nominations for SAR Drafting Team (Project 2009-02 — Real-time Tools)

The Standards Committee is seeking industry experts to serve on the Real-time Tools SAR Drafting Team (see project background below). The SAR drafting team will assist the requester in further developing the SAR and considering stakeholder comments.

If you are interested in serving on this SAR drafting team, please complete the following electronic nomination form **by June 25, 2009**: https://www.nerc.net/nercsurvey/Survey.aspx?s=3d8635074fd24fcd92689c04919d9e97

Please contact Dave Taylor at david.taylor@nerc.net with any questions about the team.

Project Background:

According to the *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*, dated April 2004, a principal cause of the August 14 blackout was a lack of situational awareness, due in part to inadequate reliability tools. Recommendation 22 of the report states, "Evaluate and adopt better real-time tools for operators and reliability coordinators." NERC's Operating Committee formed the Real-time Tools Best Practices Task Force (RTBPTF) to evaluate real-time tools and their usage within the industry. The Task Force produced a report, *Real-Time Tools Survey Analysis and Recommendations*, in March 2008 that included recommendations for the functionality, performance, and management of real-time tools.

The SAR addresses selected recommendations in the RTBPTF Report as determined by the Real-time Best Practices Standards Study Group: Project 2009-02. The intent is to describe "what" needs to be done but not "how" to do it.

More information about the project is available on the following page: http://www.nerc.com/filez/standards/Project2009-02_Real_Time_Tools.html

Standards Development Process

The Reliability Standards Development Procedure contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

Standard Authorization Request Form

Title of Proposed Standard: Project 2009-02: Real-time Tools	
Request Date: May 11, 2009	
Approved by SC: June 4, 2009	

SAR Requester Information	**SAR Type** (*Check a box for each one that applies.*)	
Name: Jack Kerr	X	New Standard(s)
Primary Contact: Dominion Virginia Power	☐	Revision to existing Standard
Telephone: 1.804.273.3393 Fax: 1.804.273.2405	☐	Withdrawal of existing Standard
E-mail: jack.kerr@dom.com	☐	Urgent Action

Purpose (Describe what the standard action will achieve in support of bulk power system reliability.)

The new standard or standards will establish requirements for the functionality, performance, and management of Real-time tools for Reliability Coordinators, Transmission Operators, and Balancing Authorities for use by their System Operators in support of reliable System operations.

Industry Need (Provide a justification for the development or revision of the standard, including an assessment of the reliability and market interface impacts of implementing or not implementing the standard action.)

According to the *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations,* dated April 2004, a principal cause of the August 14 blackout was a lack of situational awareness, which was in turn the result of inadequate reliability tools. In addition, the failure of control computers and alarm systems, incomplete tool sets, and the failure to supply network analysis tools with correct System data on August 14 contributed directly to this lack of situational awareness. Also, the need for improved visualization capabilities over a wide geographic area has been a recurrent theme in blackout investigations.

Recommendation 22 of the Blackout Report states "Evaluate and adopt better real-time tools for operators and reliability coordinators." NERC's Operating Committee formed the Real-time Tools Best Practices Task Force (RTBPTF) to evaluate real-time tools and their usage within the industry. The Task Force produced a report "*Real-Time Tools Survey Analysis and Recommendations*", dated March 13, 2008 that included recommendations for the functionality, performance, and management of Real-time tools.

This SAR addresses selected recommendations in the RTBPTF Report as determined by the Real-time Best Practices Standards Study Group: Project 2009-02.

Brief Description (Provide a paragraph that describes the scope of this standard action.)

The scope of the SAR is to establish requirements for the functionality, performance, and management of tools used in support of Real-time System Operations. The intent is to describe 'what' needs to be done but not 'how' to do it.

Detailed Description (Provide a description of the proposed project with sufficient details for the standard drafting team to execute the SAR.)

Develop a standard(s) to require the following functionality:

- Alarming – Applications or methods that emit Real-time visible and audible signals to alert Operators to events and conditions affecting the state of the Bulk Electric System (BES).

- Telemetry – Applications and methods that provide status and analog values in Real-time or near-Real-time operation.

- Network analysis – Applications and methods to be used for determining the current state of the system and simulating the impact of 'what if' system events on the current or future state of the system.

Develop a standard(s) to require that responsible entities meet identified performance metrics for the above listed functionalities including but not limited to the consideration of:

- Availability
- Quality

Those entities shall also have procedures for the above listed functionalities including but not limited to the consideration of:

- Change management
- Maintenance coordination
- Failure notification

Revise the Glossary definition of Real-time given that the acquisition and dissemination of operating data has inherent time delays. The current definition of Real-time is: Current time, as opposed to future time.

Reliability Functions

The Standard will Apply to the Following Functions *(Check box for each one that applies.)*		
X	Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area view.
X	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports Interconnection frequency in real time.
☐	Interchange Authority	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced interchange schedules between Balancing Authority Areas.
☐	Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area.
☐	Resource Planner	Develops a >one year plan for the resource adequacy of its specific loads within a Planning Coordinator area.
☐	Transmission Planner	Develops a >one year plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator area.
☐	Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).
☐	Transmission Owner	Owns and maintains transmission facilities.
X	Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
☐	Distribution Provider	Delivers electrical energy to the End-use customer.
☐	Generator Owner	Owns and maintains generation facilities.
X	Generator Operator	Operates generation unit(s) to provide real and reactive power.
☐	Purchasing-Selling Entity	Purchases or sells energy, capacity, and necessary reliability-related services as required.
☐	Market Operator	Interface point for reliability functions with commercial functions.
☐	Load-Serving Entity	Secures energy and transmission service (and reliability-related services) to serve the End-use Customer.

Reliability and Market Interface Principles

Applicable Reliability Principles *(Check box for all that apply.)*	
X	1. Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
X	2. The frequency and voltage of interconnected bulk power systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
X	3. Information necessary for the planning and operation of interconnected bulk power systems shall be made available to those entities responsible for planning and operating the systems reliably.
☐	4. Plans for emergency operation and system restoration of interconnected bulk power systems shall be developed, coordinated, maintained and implemented.
X	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk power systems.
☐	6. Personnel responsible for planning and operating interconnected bulk power systems shall be trained, qualified, and have the responsibility and authority to implement actions.
X	7. The security of the interconnected bulk power systems shall be assessed, monitored and maintained on a wide area basis.
☐	8. Bulk power systems shall be protected from malicious physical or cyber attacks.

Does the proposed Standard comply with all of the following Market Interface Principles? *(Select 'yes' or 'no' from the drop-down box.)*
1. A reliability standard shall not give any market participant an unfair competitive advantage. Yes
2. A reliability standard shall neither mandate nor prohibit any specific market structure. Yes
3. A reliability standard shall not preclude market solutions to achieving compliance with that standard. Yes
4. A reliability standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes

Unofficial Comment Form for Real-time Tools SAR (Project 2009-02)

Please **DO NOT** use this form. Please use the electronic comment form located at the link below to submit comments on the proposed Real-time Tools SAR. Comments must be submitted by **July 11, 2009**. If you have questions please contact Ed Dobrowolski at ed.dobrowolski@nerc.net or by telephone at 609-947-3673.

http://www.nerc.com/filez/standards/Project2009-02_Real_Time_Tools.html

Background Information:
According to the *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations,* dated April 2004, a principal cause of the August 14 blackout was a lack of situational awareness, which was in turn the result of inadequate reliability tools. In addition, the failure of control computers and alarm systems, incomplete tool sets, and the failure to supply network analysis tools with correct System data on August 14 contributed directly to this lack of situational awareness. Also, the need for improved visualization capabilities over a wide geographic area has been a recurrent theme in blackout investigations.

Recommendation 22 of the Blackout Report states "Evaluate and adopt better real-time tools for operators and reliability coordinators." NERC's Operating Committee formed the Real-time Tools Best Practices Task Force (RTBPTF) to evaluate real-time tools and their usage within the industry. The Task Force produced a report "*Real-Time Tools Survey Analysis and Recommendations*", dated March 13, 2008 that included recommendations for the functionality, performance, and management of Real-time tools.

This SAR addresses selected recommendations in the RTBPTF Report as determined by the Real-time Best Practices Standards Study Group: Project 2009-02. The SAR proposes developing requirements for the functionality, performance, and management of Real-time tools for Reliability Coordinators, Transmission Operators, and Balancing Authorities for use by their System Operators in support of reliable System operations, with a focus on the following functionality:

> Alarming — Applications or methods that emit Real-time visible and audible signals to alert Operators to events and conditions affecting the state of the Bulk Electric System (BES).
>
> Telemetry — Applications and methods that provide status and analog values in Real-time or near-Real-time operation.
>
> Network analysis — Applications and methods to be used for determining the current state of the system and simulating the impact of 'what if' system events on the current or future state of the system.

Please review the SAR and then answer the following questions by using the electronic comment form.

1. Do you agree that either there is a reliability-related need for the proposed standards action?

   ☐ Yes
   ☐ No
   Comments:

2. Do you agree with the scope of the proposed standards action?

   ☐ Yes
   ☐ No
   Comments:

3. The SAR emphasizes functionality, performance, and management of tools as opposed to naming specific tools. The intent is to describe 'what' needs to be done as opposed to 'how' to do it. Do you agree with this approach? If not, please state specific reasons why not.

   ☐ Yes
   ☐ No
   Comments:

4. The SAR focuses on alarming, telemetry, and network analysis. Do you agree that this is the right set of functions? If not, please state specific reasons why not.

   ☐ Yes
   ☐ No
   Comments:

5. The SAR details the need for performance metrics for availability, quality, change management, maintenance coordination, and failure notification. Do you agree that this is the correct set of metrics? If not, please state specific reasons why not.

   ☐ Yes
   ☐ No
   Comments:

6. The SAR proposes to re-define Real-time. Do you agree that a new definition is needed? If not, please state specific reasons why not. If possible, specific suggested wording for a new definition would be appreciated.

   ☐ Yes
   ☐ No
   Comments:

7. The SAR includes the Generator Operator (GOP) as a possible applicable entity. Do you agree that a potential Standards Drafting Team should have the freedom to consider the GOP as an applicable entity? If not, please state specific reasons why not.

   ☐ Yes
   ☐ No
   Comments:

8. Do you believe the proposed requirements should reside in a reliability standard or should be addressed as part of the certification process?

   ☐ Reliability Standard

   ☐ Certification Process

   Comments:

9. If you are aware of the need for a regional variance or business practice that we should consider with this SAR, please identify it here.

   Regional Variance:

   Business Practice:

   Comments:

10. If you have any other comments on this SAR that you have not already provided in response to the prior questions, please provide them here.

    Comments:

Real-Time Tools Survey Analysis and Recommendations

Final Report

March 13, 2008

Prepared by the

Real-Time Tools Best Practices Task Force

TABLE OF CONTENTS

Acknowledgments

Development of the Real-Time Tools Survey and preparation of this report between January 2004 and January 2007 would not have been possible without the contributions of many individuals working in electric power industry and for U.S. government agencies, energy companies, and regulatory organizations.

The authors wish to thank the following organizations and individuals in particular:

- The U.S. Department of Energy — Office of Electricity Delivery and Energy Reliability for the financial support to complete this work.

- Thanh Luong of the Federal Energy Regulatory Commission (FERC) for current information about FERC activities.

- Chris Bolduc of Lawrence Berkeley National Laboratory for the hardware and software to conduct the Real-Time Tools Survey.

- Steve Lee of the Electric Power Research Institute (EPRI) for guidance regarding survey development.

- Joe Eto of Lawrence Berkeley National Laboratory for his wisdom and guidance throughout the survey and report preparation process. The authors express special thanks for his ability to quickly identify and supply resources that were critical to completion of this report.

- Editors Nan Wishner and Moya Melody for the many hours they spent organizing this report into a single fluid document.

The North American Electric Reliability Corporation (NERC) thanks the members of the Real-Time Tools Best Practices Task Force (RTBPTF) for their work in developing the Real-Time Tools Survey and writing this report. NERC also acknowledges the companies for which the RTBPTF members work, for allowing the members the time necessary to complete the task force's scope of work:

Jack Kerr — Chairman, Real-Time Tools Best Practices Task Force
Dominion Virginia Power

Ed Batalla — Vice-chairman, Real-Time Tools Best Practices Task Force
Florida Power & Light Co.

Robert Kingsmore
Duke Energy Corporation

James Hartwell
Northeast Power Coordinating Council

Kenneth Thomas, Darryl G. Schrift, Jr.
PJM Interconnection, LLC

Gary Bullock
Tennessee Valley Authority

John Dumas, Tim Mortensen
Electric Reliability Council of Texas

Ed Germain
New England Independent System Operator

Alan Martin
Southern Company Services, Inc.

Bert Bressers
Southwest Power Pool

Kevin Sherd
Midwest Independent System Operator, Inc.

Grant McDonald, Rich Fetsick
Allegheny Power Systems

Vinit Gupta
Entergy

Note that the views and opinions expressed in this report are those of the contributing individuals and do not necessarily represent the views of their companies.

The authors also acknowledge the contributions of NERC staff:

- Don Benjamin helped inspire the original concept of surveying industry practices by facilitating the first RTBPTF meeting following the August 14, 2003 blackout.

- Jeff Norman and Larry Kezele coordinated the efforts of each contributor to complete the survey and assemble the final report and recommendations.

- Brian Nolan and the NERC Information Technology staff provided online access to the survey.

Finally, RTBPTF thanks all of the organizations whose responses to the survey allowed the task force to understand how real-time tools are used throughout the electric power industry in the wake of the August 14, 2003 blackout. Those organizations are listed in Appendix B, Survey Participation.

Acronyms and Abbreviations

ACE	area control error
AEC	Alabama Electric Cooperative, Inc.
AECI	Associated Electric Cooperative, Inc.
AEP	American Electric Power
AESO	Alberta Electric System Operator
AGC	automatic generation control
AP	Allegheny Power
ATC	American Transmission Company or available transfer capability
AVR	automatic voltage regulator
BA	balancing authority
BOT	Board of Trustees (NERC)
BPAT `	Bonneville Power Administration
CFE	Comision Federal De Electricidad
CFLA	critical facility loading assessment
CIN	Cinergy Corporation
CLEC	Cleco Corporation

TSIN	Transmission System Information Network
TT	thermal tracking

TVA	Tennessee Valley Authority
TTC	total transfer capability
TX	transformer
UFLS	under-frequency load-shed
UVLS	under-voltage load shed
VACAR	Virginia Carolinas (subregion of SERC)
var	volt ampere reactive
VEDI	Vectren Energy Delivery of Indiana
VSA	voltage stability analysis
VTWG	visualization tools working group
WAUW	Western Area Power Administration — Upper Great Plains Region
WEC	Wisconsin Energy Corporation
WPEL	Aquila, Inc.
WR	Westar

How to Read this Document

Because this document is long and full of survey findings, readers may find it helpful to start by skimming the **Table of Contents** to identify areas of particular interest and reviewing the **Executive Summary** for highlights of the main findings and recommendations. The table immediately following the Executive Summary lists of all of the report's recommendations.

Readers will find the in-depth overview presented in the **Introduction** helpful for understanding the interrelationships among the tools and practices covered in the report and the larger context for any particular topic of interest. The Introduction summarizes the history of Real-Time Tools Best Practices Task Force (RTBPTF), the task force's charge, the task force's comprehensive Real-Time Tools Survey of electric industry practices, the major findings and recommendations resulting from the analysis of the survey results, and proposals for next steps.

Readers interested in specific subjects will find it helpful, after reading the Introduction, to read the introductory sections on those subjects: **1.0, Real-Time Data Collection; 2.0, Reliability Tools for Situational Awareness; 3.0, Situational Awareness Practices; 4.0, Power System Models; 5.0, Support and Maintenance Tools**.

Following each introductory section are **specific subsections (1.1., 1.2, 1.3, 2.1, etc.)** that treat in detail the individual tools and practices investigated in this report. These sections define the tool, summarize the survey findings regarding it, and, if applicable, present recommendations related to the tool and its performance as well as noting areas for further research and analysis.

Readers interested in the details of where the industry should go next with real-time tools standards will find **Section 6.0, Next Steps** of interest.

Following the main text, **Appendices** describe the task force's survey development, participation, and analysis methodology as well as the Examples of Excellence discovered in the survey results. Aggregate survey responses are also available as pdfs at http://www.nerc.com/~filez/rtbptf.html.

Finally, a **Glossary** and an **Acronym** list are included to help readers manage the technical vocabulary of the document. The glossary will be especially useful for understanding the new technical terms and concepts the task force introduces in this report, including: "bulk electric system elements list," "critical applications monitoring," "critical equipment," "critical real-time tool," and "wide-area-view boundary."

Executive Summary

This report presents the findings and recommendations of the North American Electric Reliability Corporation (NERC) Real-Time Tools Best Practices Task Force (RTBPTF) regarding minimum acceptable capabilities and best practices for real-time tools necessary to ensure reliable electric system operation and reliability coordination.

RTBPTF's mission is primarily based on the U.S.-Canada Power System Outage Task Force findings that key causes of the August 14, 2003 northeast blackout included lack of situational awareness and inadequate reliability tools. That report also notes the need for visualization display systems to monitor system reliability.[1]

RTBPTF's recommendations result from an extensive, three-year process of fact-finding and analysis supported by the results of the Real-Time Tools Survey, the most comprehensive survey ever conducted of current electric industry practices.

Recommendations

RTBPTF makes major recommendations in three key areas to establish requirements that apply to reliability coordinators (RCs), transmission operators (TOPs), and other entities with similar responsibility:

1. Reliability Toolbox[2] — Require five real-time tools as well as performance and availability metrics and maintenance practices for each. The required tools are:

- Telemetry data systems
- Alarm tools
- Network topology processor
- State estimator
- Contingency analysis

2. Enhanced Operator Situational Awareness — Require standards and guidelines for situational awareness practices, including:

- Power-flow simulations
- Conservative operations plans
- Load-shed capability awareness
- Critical applications and facilities monitoring
- Visualization techniques

---

[1] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April. (Referred to in the text of this document as the *Outage Task Force Final Blackout Report*.)

[2] The relationships among the required tools are illustrated in Figure 4 of the Introduction following this Executive Summary.

The task force also recommends that NERC:

3. Address Six Major Issues to enhance the effectiveness of real-time tools:

1) Definition of the bulk electric system
2) Definition of the wide-area-view boundary
3) Development of system models and standards for exchange of model information
4) Specification of acceptable reactive reserves
5) Determination of adequate load-shed capability
6) Provision of adequate funding and staffing for maintaining and upgrading real-time tools

In addition to the major recommendations listed above, the task force makes a number of other specific recommendations related to particular real-time tools, all of which are listed in Table ES-1.

Presentation of Recommendations

The recommendations in Table ES-1 are presented throughout this report as color coded text boxes in accordance with the following color scheme:

1. Blue – Recommendations for new or revised reliability standards
2. Green – Recommendations for operating guides
3. Red – Recommendations regarding areas requiring more analysis
4. Blue-Green – Recommendations to address issues to enhance the effectiveness of real-time operation

Real-Time Tools Survey

RTBPTF's findings and recommendations are firmly grounded in the results of the Real-Time Tools Survey, a more than 300-page, web-based document with nearly 2,000 questions on a broad scope of current industry practices and plans for using real-time tools. All 17 North American RCs participated in the survey along with an additional 42 TOPs and/or Balancing Authorities (BAs) (that are not also RCs), which represent about one-third of the total number of TOPs and BAs. Thus, the survey responses reflect the current status and practices of a significant and geographically diverse portion of the North American electric industry.[3]

Focus on Situational Awareness

In this report, RTBPTF focuses on real-time tools that support system operators' situational awareness, as called for in the *Outage Task Force Final Blackout*

[3] The geographic locations of the survey participants are shown in Figure 2 (for RCs) and Figure 3 (for TOPs and BAs) of the Introduction following this Executive Summary.

Report. Situational awareness, as RTBPTF understands it, means ensuring that accurate information on current system conditions, including the likely effects of future contingencies, is continuously available in a form that allows operators to quickly grasp and fully understand actual operating conditions and take corrective action when necessary to maintain or restore reliable operations.

Next Steps

Much work lies ahead to implement the task force's recommendations for revised standards and operating guidelines to improve reliability through better real-time operating tools and practices and to conduct needed additional analyses. In the short term, RTBPTF proposes to finish work on the following activities, which will complete the remainder of the task force's assigned scope of work:

- Append recommendations for revised standards to the existing Standards Review Forms
- Provide technical support to the standards drafting teams
- Prioritize areas requiring more analysis
- Write high-level scopes for the analysis required

Following completion of these activities, RTBPTF will disband.

RTBPTF also recommends the following additional steps, which are outside the task force's assigned scope:

- The NERC Operating Reliability Subcommittee (ORS) should determine how operating guidelines are to be developed and maintained, and

- The NERC Operating Committee (OC) should consider asking the regional reliability organizations (RROs) to develop operating guidelines as "supplements" to the NERC standards.

Organization of this Report

The core, technical portion of this report is organized into five major sections that address the main subject areas of the Real-Time Tools Survey[4] and a sixth section that details the next steps toward implementing RTBPTF's recommendations:

Section 1.0, Real-Time Data Collection
Section 2.0, Reliability Tools for Situational Awareness
Section 3.0, Situational Awareness Practices

[4] The relationships among the tools and practices covered in Sections 1-5 of this report are illustrated in Figure 1 of the Introduction that follows this Executive Summary.

Section 4.0, Power System Modeling
Section 5.0, Support and Maintenance Tools
Section 6.0, Next Steps

Within each of the five major sections, a general introduction is followed by sections focusing on the main topic areas in that section. Each topical section is structured as follows:

- Definition of the specific topic
- Background on the specific topic
- Summary of Survey Findings on the specific topic
- Task Force Recommendations on the specific topic, if any, including:
    - Recommendations for New Reliability Standards
    - Recommendations for Operating Guidelines
    - Areas Requiring More Analysis
    - Examples of Excellence

A number of appendices address the Real-Time Tools Survey development (Appendix A), participation (Appendix B) and analysis (Appendix C), as well as related web links (Appendix D). Appendix E presents the Examples of Excellence in detail. A glossary and an acronym list are also included for the reader's convenience.

Summary of Recommendations

Number	*Recommendations Related to New Reliability Standards or New Requirements to Existing Standards*	Section Number	Page Number
S1	Mandate the following reliability tools as mandatory monitoring and analysis tools.		
	Alarm Tools	2.1	12
	Telemetry Data Systems	1.1	26
	Network Topology Processor	2.3	68
	State Estimator	2.5	106
	Contingency Analysis	2.6	137
S2	Compile and maintain a list of all bulk electric system elements within RC's area of responsibility.	1.1	34
S3	Add new requirements and measures pertaining to RC monitoring of the bulk electric system.	1.1	36
S4	Develop data-exchange standards.	1.2	59
S5	Develop data-availability standards and a process for trouble resolution and escalation.	1.2	61
S6	Develop a new weather data requirement related to situational awareness and real-time operational capabilities.	1.3	69
S7	Specify and measure minimum availability for alarm tools.	2.1	13
S8	Specify and measure minimum availability for network topology processor.	2.3	69
S9	Establish a uniform formal process to determine the "wide-area view boundary" and show boundary data/results.	2.2	38
S10	Develop compliance measures for verification of the usage of "wide-area overview display" visualization tools.	2.2	44
S11	Specify and measure minimum availability for state estimator, including a requirement for solution quality.	2.5	107

Number	*Recommendations Related to New Reliability Standards or New Requirements to Existing Standards*	Section Number	Page Number
S12	Specify and measure minimum availability for contingency analysis, including a requirement for solution quality.	2.6	138
S13	Specify criteria and develop measures for defining contingencies.	2.6	143
S14	Perform one-hour-ahead power-flow simulations to assess approaching SOL and IROL violations and corresponding measures.	2.8	158
S15	Provide real-time awareness of load-shed capability to address potential or actual IROL violations.	2.13	185
S16	Require BAs to monitor contingency reserves and calculate contingency reserves at a minimum periodicity of 10 seconds.	3.1	14
S17	Revise the current-day operations requirements to delineate specific, independent requirements for monitoring operating and reactive reserves.	3.1	14
S18	Establish document plans and procedures for conservative operations.	3.3	26
S19	Restore system operations from an unknown operating state to proven and reliable limits within 30 minutes.	3.3	26
S20	Develop formal operating guides (mitigation plans) and measures for each IROL and any SOL or other conditions having a potential impact on reliability.	3.4	37
S21	Review and update operating guides (mitigation plans) when day-ahead or current day studies indicate the potential need to implement an operating guide.	3.4	38
S22	Provide temporary operating guides (mitigation plans) with control actions for situations that could affect reliability but that have not been identified previously.	3.4	38
S23	Develop joint operating guides (mitigation plans) for situations that could require more than one RC or more than one TOP to execute actions.	3.4	39

Number	*Recommendations Related to New Reliability Standards or New Requirements to Existing Standards*	Section Number	Page Number
S24	Develop a formal procedure to document the processes for developing, reviewing, and updating operating guides (mitigation plans).	3.4	39
S25	Incorporate verifiable and traceable elements such as titles, document numbers, revision numbers, revision history, approvals, and dates when modifying operating guides (mitigation plans).	3.4	39
S26	Write operating guides (mitigation plans) in clear, unambiguous language, leaving nothing to interpretation.	3.4	40
S27	State the specific purpose of existence for each operating guide (mitigation plan).	3.4	40
S28	Summarize the specific situation assessment and address the method of performing the assessment in each operating guide (mitigation plan).	3.4	40
S29	Identify all appropriate preventive and remedial control actions in each operating guide (mitigation plan).	3.4	41
S30	Develop criteria in operating guides (mitigation plans) to support decisions regarding whether a specific control action should be taken.	3.4	41
S31	Incorporate on-line tools that utilize on-line data when operating guides (mitigation plans) require calculations.	3.4	41
S32	Make operating guides (mitigation plans) readily available via a quick-access method such as Web-based help, EMS display notes, or on-line help systems.	3.4	42
S33	Provide the location, real-time status, and MWs of load available to be shed.	3.5	49
S34	Establish documented procedures for the reassessment and re-posturing of the system following an event.	3.6	56
S35	Provide information to operators to maintain awareness of the availability and capability of the blackstart generators and transmission restoration paths.	3.7	64

Number	***Recommendations Related to New Reliability Standards or New Requirements to Existing Standards***	**Section Number**	**Page Number**
S36	Plan and coordinate scheduled outages of blackstart generators and transmission restoration paths.	3.7	65
S37	Maintain a Critical Equipment Monitoring Document to identify tools and procedures for monitoring critical equipment.	5.2	16
S38	Maintain event logs pertaining to critical equipment status for a period of one year.	5.2	16
S39	Maintain a Critical Equipment Maintenance and Testing Document identifying tools and procedures for maintenance, modification, and testing of critical equipment.	5.2	17
S40	Monitor and maintain awareness of critical equipment status to ensure that lack of availability of critical equipment does not impair reliable operation.	5.3	24

Number	*Recommendations Related to New Operating Guidelines*	Section Number	Page Number
G1	Identify implementation strategies and specific algorithms for conditional alarming.	2.1	14
G2	Consider human factors, ergonomics and maintenance/support issues in implementing visualization tools.	2.2	52
G3	Develop a chronological outage/return summary in network topology processor for recreating events and aiding state estimator.	2.3	73
G4	Establish state estimator solution-quality metrics to ensure accurate data and other reliability analysis.	2.5	111
G5	Identify only existing controls modeled in contingency analysis and develop conservative contingency screening criteria.	2.6	145
G6	Perform one-hour ahead contingency analysis to identify potential post-contingent problems approaching in next hour.	2.8	159
G7	Use the study real-time maintenance application to reproduce real-time snapshots.	2.9	165
G8	Develop a list of the minimum set of items that should be included in the calculations for actual and required operating reserves.	3.1	15
G9	Provide written alarm response procedures via at least one quick access method such as Web-based help or on-line help system.	3.2	20
G10	Specify the system conditions for initiating conservative operations and action plans to follow during conservative operations.	3.3	27
G11	Communicate and coordinate with neighboring systems for reassessing and re-posturing a system following an event that places the system in an insecure or unstudied state.	3.6	58

Number	***Recommendations Related to New Operating Guidelines***	**Section Number**	**Page Number**
G12	Monitor and ensure operator awareness of current conditions of blackstart generators and status of transmission restoration paths.	3.7	66
G13	Establish a change management process for performing critical equipment maintenance, modification, and testing.	5.3	27
G14	Develop a notification process when critical equipment is unavailable and an analysis/resolution process for critical equipment failures.	5.3	27
G15	Develop a critical monitoring application that interfaces to alarm tools and logs all events related to the equipment failures.	5.3	28
G16	Develop a process for monitoring critical real-time tools including change notification, status update, and severity of a situation.	5.4	35

Number	***Recommendations Related to Areas Requiring Additional Analysis***	Section Number	Page Number
A1	Investigate the impact of time skew on state-estimator solution quality.	1.2	63
A2	Identify necessary fidelity and scope of real-time models and the extent of the requisite data-exchange sets.	1.2	64
A3	Study intelligent alarm processing capability for producing a single accurate view of system status.	2.1	15
A4	Conduct research to assess current technology and practices related to the use and application of visualization tools.	2.2	53
A5	Establish a Visualization Tools Working Group (VTWG) to foster and facilitate sharing of best practices.	2.2	54
A6	Identify minimum measurement observables, adequate redundancy, and critical measurements to improve state-estimator observability and solution quality.	2.5	116
A7	Establish a pilot program to collect data and build appropriate state estimator performance metrics.	2.5	118
A8	Evaluate capability of critical facility loading assessment application in providing a backup solution if contingency analysis or the state estimator is unavailable.	2.7	150
A9	Verify accuracy of one-hour power-flow and contingency analysis results and ability to detect a potential voltage collapse revealed by a failed power-flow solution.	2.8	160
A10	Obtain additional information on how the study real-time maintenance application is utilized to enhance debugging capability.	2.9	166
A11	Assess the voltage stability assessment (VSA) application to learn how the VSA can be enhanced to become more widely used.	2.10	171
A12	Assess the dynamic stability assessment (DSA) application to learn how the DSA can be enhanced to become more widely used.	2.11	175

A13	Analyze the need to define reactive power (Mvar) capacity requirement and use a Mvar assessment application.	2.12	179
A14	Research how emergency tools and visualization techniques are used in load shedding plans.	2.13	186
A15	Analyze the need to use tools for congestion management, voltage profiles, wind-energy forecast, and weather forecast.	2.14	192
A16	Investigate processes and procedures for internal system update and external data exchange, including CIM XML models.	4.2	60
A17	Investigate whether critical application monitor tools should be independent of the critical real-time tool being monitored.	5.4	36

Number	*Recommendations Related to Major Issues to be Addressed*	Section Number	Page Number
I1	Define what constitutes bulk electric system elements and parameters as they relate to existing standards.	1.1	27
I2	Define wide-area view boundary.	2.2	38
I3	Specify acceptable reactive reserves.	3.1	13
I4	Determine adequate load-shed capability.	3.5	48
I5	Develop system models and standards for exchange of model information.	4.2	61
I6	Provide adequate funding and staffing for maintaining and upgrading real-time tools.	6.0	2

Introduction

The North American Electric Reliability Corporation (NERC) Real-Time Tools Best Practices Task Force (RTBPTF) was formed in 2004 to identify the best practices for real-time reliability tools used to build and maintain real-time network models, perform state estimation and contingency analysis, and maintain situational awareness in accordance with NERC Reliability Standards. The task force was also instructed to develop guidelines for minimally acceptable capabilities for these critical reliability tools and to recommend specific requirements to be included in reliability standards for these tools.

This report presents RTBPTF's findings and recommendations, organized by individual tool or practice under the following five major headings:

- Real-Time Data Collection
- Reliability Tools for Situational Awareness
- Situational Awareness Practices
- Modeling Practices
- Support and Maintenance Tools

In total, RTBPTF recommends:

- 40 revisions to existing NERC standards;
- 16 operating guidelines; and
- 17 areas that require more analysis

In addition, RTBPTF has assembled 24 examples of excellence in the use of real-time tools.

RTBPTF's recommendations result from an extensive, three-year process of fact-finding and analysis based on the results of the Real-Time Tools Survey, the most comprehensive survey ever conducted on current electric industry practices.

The subsections of this Introduction describe:

- the history of RTBPTF's formation
- RTBPTF's scope of work
- the Real-Time Tools Survey
- RTPBTF's major findings
- criteria by which RTBPTF's recommendations were developed
- details of RTBPTF's major recommendations
- specific proposals for next steps in NERC's work on real-time tools

Background

RTBPTF's formation and scope of work resulted from investigation of the August 14, 2003 northeast blackout by the U.S. - Canada Power System Outage Task Force and by NERC.

The passage of the Energy Policy Act of 2005 (EPAct)[1] calling for mandatory reliability standards and publication of a Federal Energy Regulatory Commission (FERC) assessment of NERC's proposed mandatory reliability standards[2] also contributed to the task force's understanding of its charge.

Blackout Investigation

The timeline leading to RTBPTF's creation begins with a December 2003 U.S.-Canada Power System Outage Task Force technical conference, which produced a series of recommendations to prevent future blackouts. Two of the conference panel discussion topics, "Operating Tools" and "Reliability Coordination," inspired the initial draft of the scope of work that was ultimately assigned to RTBPTF.

In February 2004, not long after the Outage Task Force Conference, the NERC Board of Trustees (BOT) approved the NERC Steering Group's recommended actions to prevent and mitigate future blackouts.[3] BOT directed the NERC Operating Committee (OC) to carry out Recommendation 10, which states:

> The Operating Committee shall within one year evaluate the real-time operating tools necessary for reliable operation and reliability coordination, including backup capabilities. The Operating Committee is directed to report both minimum acceptable capabilities for critical reliability functions and a guide of best practices.

The supporting discussion for Recommendation 10 states that the evaluation should include consideration of the following:

- Modeling requirements, such as model size and fidelity, real and reactive load modeling, sensitivity analyses, accuracy analyses, validation, measurement observability, update procedures, and procedures for the timely exchange of modeling data

[3] North American Electric Reliability Corporation. 2004. *August 14, 2003 Blackout: NERC Actions to Prevent and Mitigate the Impacts of Future Cascading Blackouts.* February 10. (Referred to in the text of this document as the *NERC Blackout Report*.)

- State estimation requirements, such as periodicity of execution, monitoring external facilities, solution quality, topology error and measurement error detection, failure rates including times between failures, presentation of solution results including alarms, and troubleshooting procedures
- Real-time contingency analysis requirements, such as contingency definition, periodicity of execution, monitoring external facilities, solution quality, post-contingency automatic actions, failure rates including mean/maximum times between failures, reporting of results, presentation of solution results including alarms, and troubleshooting procedures including procedures for investigating unsolvable contingencies

Next, in April 2004, the U.S.-Canada Power System Outage Task Force issued its final report.[4] Recommendation 22 of the *Outage Task Force Final Blackout Report* supports NERC's Recommendation 10. Recommendation 22 reads as follows:

> Evaluate and adopt better real-time tools for operators and reliability coordinators.
>
> NERC's requirements of February 10, 2004, direct its Operating Committee to evaluate within one year the real-time operating tools necessary for reliable operation and reliability coordination, including backup capabilities. The committee's report is to address both minimum acceptable capabilities for critical reliability functions and a guide to best practices. The [U.S.-Canada Power System Outage] Task Force supports these requirements strongly. It recommends that NERC require the committee to:
>
> A. Give particular attention in its report to the development of guidance to control areas and reliability coordinators on the use of automated wide-area situation visualization display systems and the integrity of data used in those systems.
>
> B. Prepare its report in consultation with FERC, appropriate authorities in Canada, DOE [U.S. Department of Energy], and the regional councils. The report should also inform actions by FERC and Canadian government agencies to establish minimum

[4] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April. (Referred to in the text of this document as the *Outage Task Force Final Blackout Report.*)

> functional requirements for control area operators and reliability coordinators.[5]

The *Outage Task Force Final Blackout Report* makes clear the relationship between reliability tools and electric system operator situational awareness and the role of both in causing the 2003 blackout; the report also emphasizes the need for a consistent means for operators to understand the status of the power grid outside their control areas:

> A principal cause of the August 14 blackout was a lack of situational awareness, which was in turn the result of inadequate reliability tools and backup capabilities. In addition, the failure of First Energy's control computers and alarm system contributed directly to the lack of situational awareness. Likewise, [the Midwest Independent System Operator's] MISO's incomplete tool set and the failure to supply its state estimator with correct system data on August 14 contributed to the lack of situational awareness. The need for improved visualization capabilities over a wide geographic area has been a recurrent theme in blackout investigations….
>
> The investigation of the August 14 blackout revealed that there has been no consistent means across the Eastern Interconnection to provide an understanding of the status of the power grid outside of a control area. Improved visibility of the status of the grid beyond an operator's own area of control would aid the operator in making adjustments in its operations to mitigate potential problems. The expanded view advocated above would also enable facilities to be more proactive in operations and contingency planning.

In response to Outage Task Force Recommendation 22 and NERC Recommendation 10, OC formed RTBPTF.

Mandatory Reliability Standards

As noted above, subsequent to RTBPTF's formation, passage of EPAct and publication of the *FERC Staff Assessment* of NERC's proposed mandatory reliability standards contributed to RTBPTF's understanding of its charge.

[5] Although the task force included a member from a regional council and a liaison from FERC, the consultation with "FERC, appropriate authorities in Canada, DOE, and the regional councils" to inform the development of minimum functional requirements, as envisioned in Recommendation 22, was supplanted by RTBPTF's efforts to make specific recommendations for new reliability standards.

EPAct authorized FERC to adopt mandatory reliability rules and to certify an Electricity Reliability Organization (ERO) to enforce them. Passage of EPAct made it clear that RTBPTF's recommendations for revisions to standards, if adopted, will become enforceable mandatory requirements.

In May 2006, FERC released its preliminary *Staff Assessment* of NERC's proposed mandatory reliability standards. On the topic of analysis tools in Standard IRO-002,[6] the assessment states: "[t]he standard does not have any Compliance Measures and Levels of Noncompliance and without such specificity, the ERO will not have norms that are specific enough to implement consistent and effective enforcement." This observation makes clear the need to establish performance measures for required real-time tools and practices.

On the topic of real-time monitoring in Standard TOP-006-0,[7] FERC staff states:

> [W]hile the requirements identify the data to be gathered, they fail to describe the tools necessary to turn that data into critical reliability parameters, e.g., system capability or contingency analysis, which are required to achieve situational awareness. Reliability Coordinators, Transmission Operators, and Balancing Authorities must be aware of the status of their respective systems, and such situational awareness cannot be obtained by viewing massive amounts of raw data. The standard does not contain any Measures to assess compliance with Requirements or Levels of Non-Compliance required for enforcement.

This analysis by FERC staff underscores the need to require real-time tools that present system status information in ways that operators can quickly grasp so that they can take action to correct system problems, and the need to define performance measures for standards.

RTBPTF Scope

NERC ORS and OC approved a scope of work for RTBPTF in summer 2004.[8] RTBPTF held its first meeting in September 2004 and revised the scope to add the term "situational awareness," the task of defining "best practices," and a

---

[6] "Each Reliability Coordinator shall have adequate analysis tools such as state estimation, pre and post-contingency analysis capabilities (thermal, stability, and voltage), and wide-area overview displays."
[7] "To ensure critical reliability parameters are monitored in real-time."
[8] The initial draft of RTBPTF's scope of work had been presented for consideration at a joint meeting of the NERC ORS and the NERC Reliability Coordinator Working Group (RCWG) in January 2004 and was also submitted to the NERC Steering Group in response to their invitation for comments on their proposed *NERC Blackout Report.*

notation that there may be more than one best practice (see "Understanding RTBPTF's Scope" below.) ORS accepted the revised scope in December 2004.

RTBPTF's final scope reads as follows:

1. Define and explain what is meant by the term, "Best Practice," in the context of this work scope.
2. Develop a focused survey (preferably web-based) for distribution to entities responsible for reliable operations to determine which tools those entities use to perform state estimation, perform real-time contingency analysis, and maintain situational awareness of their systems. The survey shall be designed to identify the methods and criteria these entities employ to build and maintain the necessary models and to execute and monitor the performance of the reliability tools.
3. Develop a survey of users of automated, wide-area visualization display technologies to determine guidelines for their application and the integrity of data displayed to the users.
4. Present an interim report to the ORS summarizing the results of the surveys and outlining the scope and timeline of the remaining work.
5. Conduct detailed interviews and on-site reviews of the entities identified by the survey as having the best practices in order to document how the best practices contribute to superior performance.
6. Present a report to the ORS with recommendations for specific methods, design criteria, and performance parameters and thresholds to serve as the basis for guidelines for minimally acceptable capabilities for real-time network modeling and the use and performance of network analysis tools and situational awareness tools.
7. Provide technical support for the development of new standards for real-time network models, network analysis tools, and situational awareness tools.

In performing the assigned tasks, RTBPTF shall:

1. Consider all aspects of model building and maintenance including, but not limited to, proper model size, model fidelity, real and reactive load modeling, sensitivity analyses, accuracy analyses, validation, measurement observability, update procedures, and procedures for the timely exchange of modeling data
2. Consider all aspects of state estimation including, but not limited to, periodicity of execution, monitoring external facilities, solution quality, topology error and measurement error detection, failure rates including

mean/max times between failures, presentation of solution results including alarms, and troubleshooting procedures

3. Consider all aspects of real-time contingency analysis including, but not limited to, contingency definition, periodicity of execution, monitoring external facilities, solution quality, post-contingency automatic actions, failure rates including mean/max times between failures, reporting of results, presentation of solution results including alarms, and troubleshooting procedures including procedures for investigating unsolvable contingencies
4. Consider all elements of situational awareness in the NERC Operating Standards
5. Identify issues where best practices are nonexistent or insufficient
6. Recognize that there may be more than one "best practice" for a particular aspect of tool utilization and support
7. Consider other tools currently in use to supplement or back up state estimators or real-time contingency analysis applications
8. Address human factors engineering ("man-machine interface")
9. Investigate minimum staffing requirements to support real-time tools
10. Address real-time data acquisition, quality, and time-stamping for data used to drive real-time tools
11. Address management understanding of and commitment (funding and people) to provide appropriate tools and support
12. Identify and consider similar work that may have already been done within the Regions or sub-regions
13. Identify and consider similar work that may have already been published by EPRI [Electric Power Research Institute], IEEE [Institute of Electrical and Electronics Engineers], or other organizations
14. Take into account regional differences in preparing the interim guidelines and final recommendations.

Understanding RTBPTF's Scope

RTBPTF's understanding of its scope depends on three key concepts: the meaning of the term "best practices," the meaning of the term "situational awareness," and the relationships among real-time reliability tools and practices. The task force's considered interpretation of these three key concepts is fundamental to its approach to its work and to the structure of this report.

Best Practices

The first assignment in RTBPTF's scope is to define the term "best practice" as it applies to the task force's charge. However, the concept of best practices extends beyond RTBPTF's scope; OC created the Best Practices Task Force to define this term and identify where or how best practices apply.

The OC Best Practices Task Force final report[9] states:

> The reports following the August 14, 2003 blackout specifically referred to 'best practices,' and the U.S.-Canada Power Outage Task Force final report of April 5, 2004 suggested that the industry establish best practices in certain areas. But these reports and recommendations did not define what best practices were – they assumed the reader would infer the meaning from the context of the report or recommendation.

The Best Practices Task Force report lists specific recommendations from the blackout reports that refer to best practices and summarizes its mission by stating:

> NERC is addressing these recommendations in various reports, documents, and on-going committee tasks. But after considerable research, the task force found there was no single definition of best practices. We also hear the term best practices in reports and committee discussions now and then to describe procedures that, while not standards, are generally accepted as "good things to do," and that work well. However, NERC has never attempted to either define best practices or suggest where or how they could be used. Are best practices in some unique way better than guidelines or examples of excellence? Or do people refer to best practices in the more general sense of "these are good things to do," or "these are ways to achieve excellence?"

The OC's Best Practices Task Force conclusions can be paraphrased as follows[10]:

- NERC has adopted a comprehensive set of mandatory reliability standards, and the Best Practices Task Force believes that adding a comprehensive collection of voluntary practices that represent the years of wisdom and achievements in interconnected systems operation would be a worthwhile goal.

---

[9] *Best Practices Task Force Report: Discussions, Conclusions, and Recommendations*. 2005. December 1.

[10] These conclusions are paraphrased from the *Best Practices Task Force Report: Discussions, Conclusions, and Recommendations.* 2005. December 1.

These practices (aptly termed as “good things to do”) would complement existing NERC mandatory reliability standards.

- The Best Practices Task Force believes that there are several existing sources within NERC that can be drawn upon to serve the purpose stated above. These include Examples of Excellence, former NERC Operating Guides, Regional Guides, and surveys of operating practices (e. g., RTBPTF Survey).
- The Best Practices Task Force sees no need to develop a separate set of documents called best practices because that term does not have a uniform definition in our industry; it means different things to different people. Operating Guidelines, as well as NERC’s Examples of Excellence, will provide two different kinds of resources for promoting operations excellence. Both are developed by industry experts for industry experts, relate well to the standards, can provide meaningful recommendations for promoting excellence in systems operation, and are voluntary. The key difference between examples of excellence and operating guidelines is that the former are unique to individual organizations and may not apply to the wide interests of the industry, while the latter are more applicable across the industry. Both are valuable, but are not substitutes for one another.

RTBPTF adopted the Best Practices Task Force recommendations and organized RTBPTF deliverables accordingly. Thus, the reader will see in this report, where applicable, recommendations for operating guidelines and descriptions of examples of excellence. (Examples of excellence are listed briefly in the applicable sections of the report and described in more detail in Appendix E).

Situational Awareness

Because lack of situational awareness was determined to be central to causes of the 2003 blackout and because this term clearly expresses the purpose of using real-time reliability tools, RTBPTF explicitly added “situational awareness” to its scope.

RTBPTF defines “situational awareness” as ensuring that accurate information on current system conditions is continuously available to operators. This includes information on the current state of bulk electric system elements as well as on the potential impact of contingencies that might affect these elements. This information must be accurate, dependable, timely, and comprehensive enough for operators to rapidly and fully understand actual operating conditions and take corrective action when necessary to maintain or restore reliable operations.

Relationships Among Real-Time Tools and Practices

The real-time reliability tools that are the core subject of this report[11] are fundamental to operators' situational awareness and ability to take prompt, effective corrective action. However, the quality of information supplied by these tools depends on the quality of telemetry and other real-time data as well as on situational awareness practices, system modeling practices, and tool maintenance and availability. The task force's understanding that all these elements are necessary for operator situational awareness was central to its decision to address the following tools and practices:

Real-Time Data Collection — Collecting raw real-time data is the first step in the complex process of producing the accurate, dependable, readily understood information that operators need to maintain situational awareness. Real-time models must be updated with the current status of all modeled elements and the current values of power flows and voltages so that tools such as the network topology processor and state estimator can convert these data into the accurate and dependable information operators need to maintain situational awareness. Thus, RTBPTF included real-time data collection in its scope.

Situational Awareness Practices – Information from real-time reliability tools is only meaningful if operators know how to act on it – that is, how to modify operational strategy in response to real or potential degradation in the reliability of the portion of the bulk electric system for which they are responsible. In some situations, documented procedures ("situational awareness practices") must be established to ensure that operators know the possible or required actions to take. Because it is essential that the information provided by real-time reliability tools allows operators to act to maintain system reliability, RTBPTF included situational awareness practices in its scope.

Modeling Practices — Real-time tools, such as the state estimator and contingency analysis, require a real-time mathematical model of some portion of the bulk electric system in order to function. The size, scope, and content of the required model are functions of the size, location, and scope of responsibility of the entity using the real-time tools. Even the best-designed, advanced tools can be severely compromised by inaccuracies and omissions in the network models upon which they rely. The value of the information provided to operators by real-

[11] RTBPTF focuses only on real-time tools to aid system operators' situational awareness, as called for by the NERC and Outage Task Force reports on the investigation of the 2003 blackout. Thus, RTBPTF's investigation did not include long-term, medium-term, day-ahead, or training tools although the task force recognizes that these tools may be essential for carrying out entities' other reliability-related responsibilities. Similarly, RTBPTF did not consider real-time tools related to market or economic operations.

time reliability tools thus depends heavily on the practices used to build and maintain the requisite models. Therefore, RTBPTF included modeling practices in its scope.

Support and Maintenance Tools – Operators need to be aware of the status of their real-time tools. If a computer problem, data-link failure, or other circumstance interferes with the function of a real-time tool, the operators who rely upon that tool need to be informed so that they will not unknowingly rely on outdated or incorrect information and can take appropriate backup steps. Therefore, RTBPTF included operator awareness of the availability of real-time tools in its scope.

Figure 1 illustrates the interrelationships of the five major topics addressed in this report. Each category represented in Figure 1 is a major section heading in both the Real-Time Tools Survey and this report, as explained in more detail in the sections on the survey, task force recommendations, and report organization below. The RTBPTF adopted an inclusive perspective by explicitly addressing supporting applications, practices, and processes related to real-time tools.

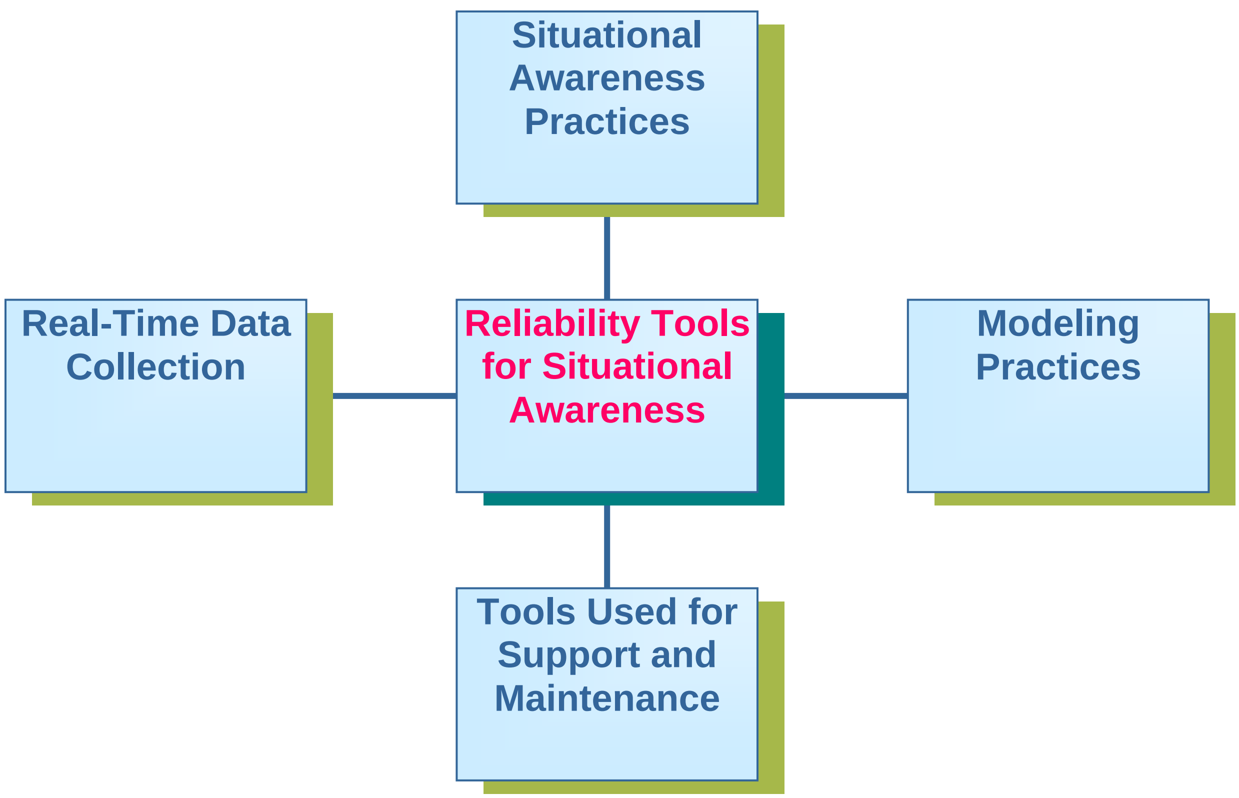

Figure 1. Real-Time Tools and Supporting Practices and Processes.

Survey Approach and Analysis

RTBPTF's principal activity was the development, administration, and analysis of the Real-Time Tools Survey. From fall 2004 through spring 2005, RTBPTF developed the survey, which gathered detailed information on the topics below. For more information on the survey's development, please see Appendix A.

Real-Time Data Collection

This section of the survey addresses the following real-time data, which are needed as input for real-time reliability applications:

- Telemetry data
- Inter-control center communications protocol (ICCP)-specific data
- Miscellaneous data

The questions in this section of the survey focus on the types of telemetry and other near-real-time data that respondents use in Supervisory Control and Data Acquisition/Energy Management System (SCADA/EMS) and network and other applications to monitor the bulk electric system. The data addressed in this section could come from SCADA, ICCP (or other forms of inter-utility data links), Inter-regional security network (ISN), or other systems communicating in continuous real- or near-real-time operation.

Modeling Practices

This section of the survey addresses two topics related to real-time network models:

- Model characteristics
- Modeling practices and tools

The questions in this section of the survey focus on several issues, including, but not limited to: model size, model fidelity, real and reactive load modeling, sensitivity analysis, accuracy analysis, validation, measurement observability, and update and data exchange procedures.

Reliability Tools for Situational Awareness

This section of the survey covers tools used to ensure reliable operations and maintain situational awareness, including:

- Alarm tools
- Visualization tools
- Network topology processor
- Topology & analog error detection
- State estimator
- Contingency analysis
- Critical facility loading assessment (CFLA)

- Power flow
- Study real-time maintenance (SRTM)
- Voltage stability assessment
- Dynamic stability assessment
- Capacity assessment application
- Emergency tools
- Other current, operational tools
- Other future tools

Situational Awareness Practices

This section of the survey addresses operating practices, processes, and procedures that support or maintain situational awareness in the following areas:

- Reserve monitoring
- Alarm response
- Conservative operations
- Operating guides (mitigation plans)
- Load-shed capability awareness
- System reassessment and reposturing
- Blackstart capability awareness

The questions in this section of the survey focus on eliciting information about practices to ensure that operators a) have the information they need to be aware of potentially unreliable system conditions and b) know what actions they can take to maintain reliability.

Support and Maintenance Tools

This section of the survey addresses support tools and practices that are essential to ensuring the integrity and availability of real-time reliability tools, including:

- Display maintenance tool
- Change management tools & practices
- Facilities monitoring
- Critical applications monitoring
- Trouble reporting tool

Survey Participation

The survey was administered in summer and fall of 2005 through a secure, web-based server hosted by NERC in Princeton NJ.[12] RTBPTF invited survey

[12] Lawrence Berkeley National Laboratory developed the software implementation and web interface for the survey and created a database and software tools to aid RTBPTF in analyzing survey results. NERC and RTBPTF members gratefully acknowledge the support of Lawrence Berkeley National Laboratory of the U.S. Department of Energy, Office of Electricity Delivery and Energy Reliability for these activities.

responses from all registered reliability coordinators (RCs), transmission operators (TOPs), balancing authorities (BAs), and any other entity using real-time tools.

The response to the survey was excellent, especially in view of its length and the considerable effort required completing it. As shown in Figure 2, all 17 North American RCs participated in the survey. Figure 3 shows the additional 42 TOPs and/or BAs (that are not also RCs) that participated. This level of participation means that the survey responses provide a comprehensive snapshot of the current practices of a significant and geographically diverse portion of the North American electric industry. For more information on survey participation, please see Appendix B.

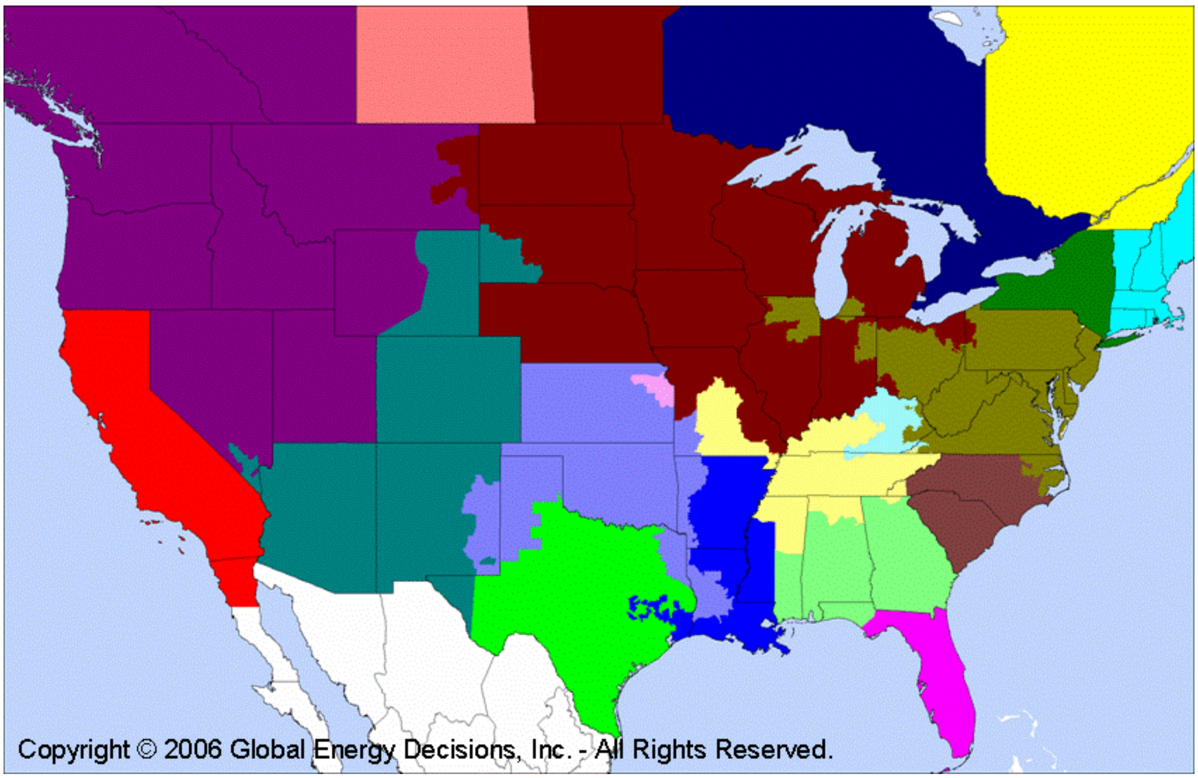

Figure 1 – Footprint of RCs that participated in the Real-Time Tools Survey

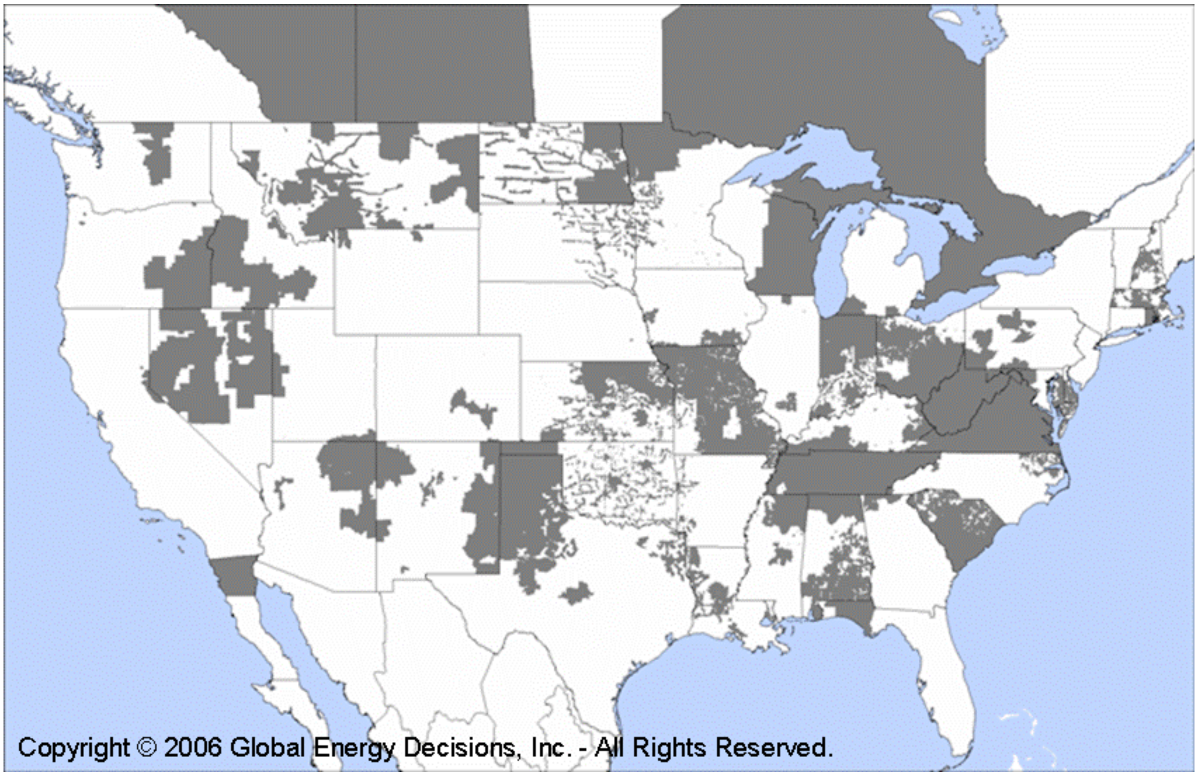

Figure 2 – Footprint of TOPs and BAs (that are not also RCs) that participated in the Real-Time Tools Survey

Survey Analysis

RTBPTF analyzed the survey responses in 2006. First, the task force distilled initial findings by topic and reviewed these findings in relation to the *Outage Task Force Final Blackout Report*, *NERC Blackout Report*, and other relevant background material. The task force focused on issues directly related to reliability, i.e., findings related to tools and situational awareness issues that had been identified as causes of the blackout. RTBPTF identified patterns of similar responses that indicated prevailing industry practices and then reviewed existing reliability standards to see how these tools and issues were addressed. Finally, the task force identified major issues that needed to be resolved. For more information on the survey analysis methodology, please see Appendix C.

The task force's findings are summarized in the next section below.

Overview of Findings

Based on its analysis of the Real-Time Tools Survey results, the task force made a large number of findings. The key findings for each major section of the report are summarized below with reference to the task force's relevant major recommendations, which are presented in more detail in the Recommendations section later in this introduction.

Real-Time Data Collection

RTBPTF finds that adequate, timely, accurate telemetry data on the current status of bulk electric system elements are essential for situational awareness. Bulk electric system elements that have the potential to impact system operations by causing a system operating limit (SOL) or interconnected reliability operating limit (IROL) violation and that are within an entity's footprint or adjacent to it should be telemetered. Accordingly, telemetry data systems are among RTBPTF's five recommended mandatory real-time tools, as described in the Recommendations section below. RTBPTF also recommends that NERC and the industry clarify the definition of bulk electric system elements and the wide-area-view boundary for telemetry data, consistent with this impact-based definition.

RTBPTF's analysis of the survey findings related to real-time data collection and all of the task force's recommendations on this topic are found in the following sections of this report: Section 1.0, Real-Time Data Collection; Section 1.1, Telemetry Data; Section 1.2, ICCP-Specific Data; and Section 1.3, Miscellaneous Data.

Reliability Tools for Situational Awareness

RTBPTF concludes that situational awareness requires, at a minimum:

- Functioning alarms that notify operators of current or potential violations of limits

- Timely and accurate network topology processing and state estimation to ensure that alarms can be reliably processed (when appropriate) and that meaningful contingency analysis can be performed

- Timely and accurate contingency analysis to identify potential SOL or IROL violations

Accordingly, alarm, network topology processing, state estimation, and contingency analysis tools are included in RTBPTF's five recommended mandatory real-time tools. Additional real-time tools and processes for power flow, load-shed capability, and visualization techniques are included as part of other RTBPTF recommendations.

RTBPTF's analysis of the survey findings related to real-time tools for situational awareness and all of the task force's recommendations on this topic are found in the following sections of this report: Section 2.0, Reliability Tools for Situational Awareness; Section 2.1, Alarm Tools; Section 2.2, Visualization Techniques; Section 2.3, Network Topology Processor; Section 2.4, Topology and Analog Error Detection; Section 2.5, State Estimator; Section 2.6, Contingency Analysis;

Section 2.7, Critical Facility Loading Assessment; Section 2.8, Power Flow; Section 2.9, Study Real-Time Maintenance; Section 2.10, Voltage Stability Assessment; Section 2.11, Dynamic Stability Assessment; Section 2.12, Capacity Assessment; Section 2.13, Emergency Tools; Section 2.14, Other Tools (Current and Operational). [An additional section, Section 2.15 Other Tools (Future), was planned but is omitted from this report because the survey responses yielded insufficient information on this topic.]

Situational Awareness Practices

The task force concludes that documented conservative operations practices are a key element of situational awareness practices and thus includes conservative operations plans in its recommendations. The task force also recommends, in its list of major issues that should be addressed to enhance the effectiveness of real-time tools, that NERC and the industry specify what constitutes acceptable reactive reserves and load-shed capability.

RTBPTF's analysis of the survey findings related to situational awareness practices and all of the task force's recommendations on this topic are found in the following sections of this report: Section 3.0, Situational Awareness Practices; Section 3.1, Reserve Monitoring; Section 3.2, Alarm Response Procedures; Section 3.3, Conservative Operations; Section 3.4, Operating Guides; Section 3.5, Load-Shed Capability; Section 3.6, System Reassessment and Re-posturing; Section 3.7, Black-Start Capability.

Power System Modeling

Although defining the elements represented in internal network models is relatively straightforward, the task force finds that defining the elements to be represented in external models is much more complex. External models must be appropriately sized and adequately updated and maintained to ensure that they can accurately represent pre- and post-contingency conditions. RTBPTF recommends that NERC and the industry develop criteria, guidelines, and standards for internal and, especially, external system models as well as data exchange. As with telemetry data, RTBPTF recommends defining what constitute bulk electric system elements and the wide-area view based on the potential impacts of these elements on an entity's ability to operate reliably; these definitions should form the basis for model development and data exchange standards.

RTBPTF's analysis of the survey findings related to power system modeling and all of the task force's recommendations on this topic are found in the following sections of this report: Section 4.0, Power System Models; Section 4.1, Model Characteristics; Section 4.2, Modeling Practices and Tools.

Support and Maintenance Tools

RTBPTF finds that RC and TOP control centers use a variety of applications and practices to monitor the status of real-time tools and supporting computer systems and communications networks. Thus, RTBPTF's recommendations include requirements for critical applications and facilities monitoring tools.

RTBPTF's analysis of the survey findings related to support and maintenance tools and all of the task force's recommendations on this topic are found in the following sections of this report: Section 5.0, Support and Maintenance Tools; Section 5.1, Display Maintenance Tool; Section 5.2, Change Management Tools and Practices; Section 5.3, Facilities Monitoring; Section 5.4, Critical Applications Monitoring; Section 5.5, Trouble Reporting Tool.

Criteria for Developing Recommendations

RTBPTF formulated its recommendations for real-time tools based on its survey analysis and on the following five key criteria, which the task force developed based on its assigned scope and the results of the 2003 blackout investigation:

1. Support NERC Reliability and Market Interface Principles.[13]

2. Address current needs and known gaps, such as those identified in the August 14, 2003 blackout reports by NERC and the Outage Task Force and in the *FERC Staff Assessment*. (RTBPTF also considered recommendations made by FERC Consultant Frank Macedo in his presentation, "Reliability Software: Minimum Recommendations and Best Practices," at the July 14, 2004 FERC technical conference.)[14]

3. Represent effective and feasible practices that are prevalent in the industry today. That is, the recommendations must be supported by the survey findings.

4. Identify performance requirements for which compliance can be assessed unambiguously and, to the extent defensible based on survey findings, through the use of quantitative metrics.

5. Represent the consensus of active RTBPTF members.

Recommendations

RTBPTF's major recommendations are summarized below. A summary list of all the recommendations in this report is presented in Table ES-1. The details of each recommendation appear in the relevant subsection of the report.

RTBPTF makes major recommendations in three key areas. The first two recommendations summarized below apply to RCs, TOPs, and other entities with similar responsibility:

1. Reliability Toolbox – Require five real-time tools as well as performance and availability metrics and maintenance practices for each. The required tools are:

- Telemetry data systems
- Alarm tools
- Network topology processor
- State estimator
- Contingency analysis

2. Enhanced Operator Situational Awareness – Require standards and guidelines for situational awareness practices, including:

- Power-flow simulations
- Conservative operations plans
- Load-shed capability awareness
- Critical applications and facilities monitoring
- Visualization techniques

The task force also recommends that NERC:

3. Address Six Major Issues to enhance the effectiveness of real-time tools:

1) Definition of the bulk electric system
2) Definition of the wide-area-view boundary
3) Development of system models and standards for exchange of model information
4) Specification of acceptable reactive reserves
5) Determination of adequate load-shed capability
6) Provision of adequate funding and staffing for maintaining and upgrading real-time tools

Each of these recommendations is described in more detail below.

Require the Use of Five Real-Time Tools

RTBPTF recommends that, to ensure reliability monitoring of the bulk electric system and maintenance of situational awareness, five real-time tools become mandatory with quantitative measures for minimum acceptable levels of performance for both RCs and TOPs (as a revision to TOP-006).[15] These required tools should be viewed as the core elements of an operator's "reliability toolbox." Figure 4 illustrates the relationships among these tools (and supporting applications).

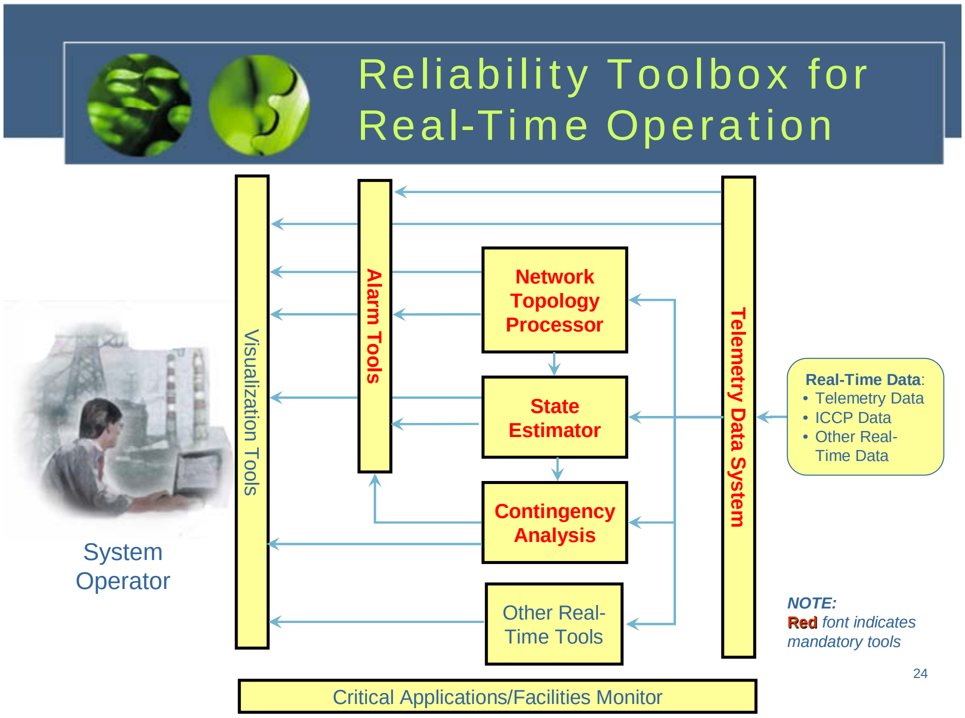

Figure 4 – Reliability Toolbox

RTBPTF recommends that the use of these five real-time tools be mandatory for all RCs and TOPs. RTBPTF further recommends that these requirements apply to any entity that has been delegated responsibility, by an RC or TOP, to operate these tools, regardless of the entity's registered designation. "Delegated responsibility to operate these tools" means the entity uses any of these tools to support or complement the RC's or TOP's ability to operate the bulk electric system reliably in accordance with formal agreements, contracts, or previously established practices or procedures.

---

15 RTBPTF recognizes that differences will arise naturally between TOPs and RCs in the use of these tools. For example, the definition of the wide-area boundary (for RCs) and the "local" transmission system (for TOPs) will have implications for the scope of the network model that each relies upon.

Mandatory Tool #1: Telemetry Data Systems – Telemetry data systems update status and analog values from SCADA/EMS (via ICCP, ISN, etc.) continuously in real time or near-real time. These systems are the primary direct and indirect sources of situational awareness for operators (they function as indirect sources when they support other applications).

RTBPTF recommends modifying existing standards to require telemetry data system use. The task force also makes four supporting recommendations for telemetry data systems:

1) Increase the minimum update frequency for operational reliability data from once every 10 minutes to once every 10 seconds.[16]

2) Standardize the procedures, processes, and rules governing key data exchange issues.[17]

3) Institute a requirement for data availability from ICCP or other equivalent systems, based on the ratio of "good" data received (as defined by data quality codes) to total data received. The ratio must exceed 99 percent for 99 percent of the sampled periods during a calendar month. In addition, the ratio must not be less than 99 percent for any 30 consecutive minutes.

4) Establish minimum response times for restoration of data exchange between control centers following the loss of a data link or other problems within the source system. As part of this requirement, a trouble-resolution process standard must be developed that requires all entities responsible for management and maintenance of ICCP or equivalent systems to identify, with data recipients that could be affected by a loss of data exchange capability, a mutually agreeable restoration target time. The standard process must also include service-restoration escalation procedures and prioritization criteria.

RTBPTF recognizes that the many parties involved in monitoring, transmitting, and receiving data share the responsibility for maintaining the availability of high-quality data. Assignment of specific responsibilities for sub-par performance is not within RTBPTF's scope but should be considered as part of the standards development process.

[16] Section 1.1, Telemetry Data, contains a complete list of data elements to which the recommended update frequency should be applied.

[17] These issues include: interoperability of ICCP and equivalent systems, data access restrictions, data-naming conventions, change management and coordination, joint testing and data checkout, quality codes, and dispute resolution.

Mandatory Tool #2: Alarm Tools – Alarm tools give real-time visual and audible signals to alert operators and others about events affecting the state of the bulk electric system. Alarms may be initiated by information transmitted directly from telemetry data systems or other applications, such as the state estimator and contingency analysis. Alarms are essential for ensuring operator situational awareness.

RTBPTF recommends modifying existing standards to require use of alarm tools. RTBPTF also recommends mandatory processes to help ensure that alarm tools are always available. RTBPTF supports filtering, prioritizing, and grouping alarms as an important feature common to most alarm tools. However, the task force does not recommend making additional intelligent alarm-processing capabilities mandatory at this time because survey results show that adoption of these capabilities is not yet widespread in the industry.

Mandatory Tool #3: Network Topology Processor – A network topology processor can be used in more than one way: to support visualization tools in identifying electrical islands or isolated or open-ended equipment, and to convert a nodal network model, based on SCADA breaker and switch statuses, into a bus-branch model for use by other network applications. Use of this tool for the latter purpose is essential because two applications that are mandatory for situational awareness, the state estimator and contingency analysis, cannot be run without this conversion.

RTBPTF recommends modifying existing standards to require use of a network topology processor.[18] RTBPTF also recommends specific availability requirements, which depend on the functions supported by the tool.

Mandatory Tool #4: State Estimator – A state estimator performs statistical analysis using imperfect, redundant telemetered data from the power system and a power system model to assess the system's current condition. State estimator output is the primary input for all network analysis applications, such as contingency analysis and power flow, and can also be used to generate alarms for overloads or voltage problems on branches and buses. If the state estimator is not working or is working incorrectly, real-time network analysis, such as contingency analysis, either cannot be performed or will not produce valid results. Situational awareness depends on valid contingency analysis results.

RTBPTF recommends modifying existing standards to require use of a state estimator. RTBPTF also recommends specifying minimum requirements for the availability of valid, useful state estimator results based on two metrics:

---

[18] This and the following RTBPTF recommendations for two additional mandatory real-time tools should be viewed jointly. For example, RTBPTF recognizes that a network topology processor is sometimes maintained as an integrated process within a state estimator.

1) The state estimator must have at least one converged solution (i.e., a state-estimated solution) for at least 97.5 percent of clock 10-minute periods (six non-overlapping periods per hour) during a calendar month, and

2) The state estimator must have at least one converged solution (i.e., a state-estimated solution) for every continuous 30-minute interval during a calendar day.[19]

The quality of state estimator solutions needs to be formally addressed, but RTBPTF concludes that more analysis is required to formulate and specify technically defensible solution-quality metrics and performance requirements. RTBPTF maintains that specification of a single performance metric and target would be inappropriate at this time. Other, corollary issues must be considered, such as whether external model specification is adequate and whether the telemetry data upon which the state estimator depends are valid. Until these issues are addressed, focus on a specific performance metric and target will lead to a false sense of security regarding the quality of state estimator solutions. Thus, at this time, RTBPTF recommends the development of operating guidelines for solution-quality metrics and a parallel process of tracking and analyzing state estimator performance.[20]

Mandatory Tool #5: Contingency Analysis – A contingency analysis tool simulates power flow for a set of contingencies and calculates the post-contingency thermal loading on and/or voltages at a set of monitored facilities. The results from contingency analysis identify potential SOL and IROL violations. These results, in turn, inform alarm tools (including visualization tools) and may initiate other applications.

RTBPTF recommends modifying existing standards to require contingency analysis. RTBPTF also recommends specifying minimum acceptable availability and use of contingency analysis, the definition of contingencies with respect to relay actions, and procedures for addressing failed contingency analysis:

1) Contingency analysis must be run in conjunction with a converged state estimator solution for at least 97.5 percent of clock one-minute periods (six non-overlapping periods per hour) during a calendar month.

---

[19] These timing requirements are consistent with NERC's mandate to MISO to fully implement and test its state estimator and contingency analysis tools "to ensure that they can operate reliably no less than every 10 minutes" (see the *NERC Blackout Report*). These requirements are also consistent with the requirement that operators must be aware of IROL and SOL violations and be able to take action to address them within no more than 30 minutes.

[20] Examples of solution-quality metrics that should be considered include: trend of cost index (sometimes called a "performance index"), trend of number of anomalous measurements, ranked normalized residuals of individual measurements, maximum MW and Mvar mismatch, trend of number of iterations, and major topology changes.

2) Contingency analysis must be run at least once for every continuous 30-minute interval during a calendar day.[21]

3) Real-time contingencies must be defined so that they accurately reproduce the results of the actions of protective relays, which remove elements from service to minimize damage or stop the spread of undesirable system conditions.[22]

4) The total number of “unsolved” contingencies (i.e., contingencies for which the power flow fails to converge and therefore does not produce a solution) must be recorded, at a minimum, every 30 minutes. The actions taken to resolve unsolved contingencies and procedures to investigate and resolve unsolved contingencies must be documented.

Because the Reliability Toolbox is an overarching recommendation that draws on findings from many sections of this report, the rationale for this recommendation and the recommended wording for the revisions to standard TOP-006 appear, in the same format as used for the other recommendations throughout this report, in a separate section, Reliability Toolbox Recommendation and Rationale, following this introduction.

Require Supporting Tools and Practices

RTBPTF makes several major recommendations regarding tools and practices that support the five mandatory real-time tools in the Reliability Toolbox:

Power Flow – The power-flow application calculates the state of the power system (flows, voltages, and angles) using available input data for load, generation, net interchange, and facility status. On-line power flow is widely used to assess system conditions or perform look-ahead analysis. It is also used in “n-1” contingency analysis and to identify potential future voltage collapse or reliability problems.

[21] The justifications for these two performance metrics and minimum acceptable performance targets are the same as those described previously for the state estimator.

[22] This recommendation is intended to clarify the current reliability standard to ensure that the list of contingencies includes all bulk electric system elements that, when out of service, can cause an SOL or IROL violation or overload on any other facility. In other words, although NERC standard FAC-010 considers only individual bulk electric system elements, RTBPTF recommends that the definition of a single contingency, for the purpose of this recommendation, include explicit consideration of network topology. This is to ensure that single events that result in the simultaneous outage of multiple bulk electric system elements are analyzed.

RTBPTF recommends revising existing standards to require RCs and TOPs to perform one-hour-ahead power-flow simulations following critical system events, extreme load conditions, large power transactions, and major planned outages.

Conservative Operations – Conservative operations refer to intentional, proactive practices in response to unknown, insecure, or potentially risky system conditions. Conservative operations are intended to move the system to a known, secure, and low-risk operating posture. For example, the power system is postured differently for different impending conditions, such as hurricanes, ice storms, cold fronts, etc.

RTBPTF recommends revisions to and coordination among several existing reliability standards to require that each RC and TOP have documented conservative operations plans and procedures. These plans and procedures must identify credible conditions that could lead to an unknown, insecure, or potentially risky operating state and the appropriate actions that operators are expected to take in response.

Awareness of Load-Shed Capability – Load-shed capability awareness is current knowledge of the status, availability, magnitude, and time-to-deploy of all customer load that can be dropped on an emergency basis. Without this knowledge, RCs and TOPs cannot ensure that they can successfully perform this control action of last resort; this knowledge is an essential element of situational awareness.

RTBPTF recommends modifying existing standards to require operator awareness of actual load-shed capability in real time. However, RTBPTF recognizes that procedures for determining the amount, location, and maximum time-to-deploy of load-shed resources must be clarified. This topic is addressed separately below as one of the six major issues RTBPTF recommends that NERC and the industry address to enhance the effectiveness of real-time tools.

Critical Applications and Facilities Monitoring – Critical applications and facilities monitoring tracks the status and availability of real-time tools, including, but not limited to, the five recommended mandatory tools described above. As noted earlier, RTBPTF recommends measurable indices of performance (metrics) and minimum performance requirements based on these indices for each of the five mandatory tools, to ensure that the data produced by those tools are meaningful. However, critical applications and facilities monitoring is also needed to ensure that the information provided by these tools is current and continuously available to operators and technical support staff.

RTBPTF recommends requirements for a separate process (or support tool) that continuously monitors the availability and status of the five mandatory reliability tools as well as other critical tools.[23] RTBPTF also recommends mandatory reporting requirements for event logs and maintenance documentation.

Visualization Techniques **–** Visualization techniques are a group of user-interface applications, tools, and displays that provide concise visual monitoring and enhanced multiple views of relevant power system data in real time to operators and others.

RTBPTF recommends modifying existing IRO and TOP reliability standards to require the use of visualization tools as part of the measures for compliance with existing NERC reliability standards. RTBPTF also endorses ongoing efforts to research and develop visualization techniques consistent with Recommendation 13 of the *Outage Task Force Final Blackout Report.*

RTBPTF also recommends that NERC:

1) Establish a Visualization Tools Working Group (VTWG) to foster and facilitate sharing of industry best practices for use of visualization tools. This working group could continue to recommend and develop standards and operating guidelines for best methods and practices for presenting information to operators.

2) Establish industry and technical forums, involving academic, research, and other organizations, that focus on visualization tools.

Address Six Issues to Enhance the Effectiveness of Real-Time Tools

RTBPTF's above recommendations stand on their own, and NERC and the industry should implement these recommendations as soon as practicable. In addition, RTBPTF has identified six issues that are closely related to its recommendations and that NERC and the industry should address to enhance the effectiveness of real-time tools.

Issue #1: Bulk Electric System Elements Should be Defined. The effectiveness of several of RTBPTF's recommendations depends on the adequacy of telemetry, modeling, and exchange of appropriate data regarding bulk electric system elements. RTBPTF recommends that NERC and regional reliability organizations (RROs) define criteria for what constitute bulk electric system elements and that

[23] RTBPTF notes that NERC cyber-security standards address the availability of critical tools. However, cyber-security standards do not address operator situational awareness. Cyber-security standards focus primarily on protecting and securing critical cyber assets (e.g., CIP-007) and do not adequately acknowledge or address operators' needs for these tools to monitor the bulk electric system and maintain situational awareness.

RCs create and maintain a comprehensive, consistent list of all bulk electric system elements within their respective footprints.

In support of actions by others to define bulk electric system elements and based on RTBPTF's system-operations perspective, the task force recommends basing the definition of bulk electric system elements on a clear, unambiguous NERC and regionally approved impact-based methodology. Application of this method should lead to a definition of bulk electric system elements that refers only to electrical facilities that, if out of service, could lead to an SOL or IROL violation. RTBPTF does not support a definition of bulk electric system elements that is based on electrical characteristics. RTBPTF formulated all of its recommendations from this perspective.[24] The task force notes this perspective both to inform ongoing industry discussions and to provide a context for its own recommendations.

Issue #2: The Wide-Area Boundary Should be Defined. Standard IRO-003's Purpose Statement says that "[t]he Reliability Coordinator must have a wide area view of its own Reliability Coordinator Area and that of neighboring Reliability Coordinators." The NERC glossary defines "wide area" as "[t]he entire Reliability Coordinator Area as well as the critical flow and status information from adjacent Reliability Coordinator Areas as determined by detailed system studies to allow the calculation of Interconnected Reliability Operating Limits."

RTBPTF defines "wide-area view" as the monitoring boundary for RCs. Several of RTBPTF's recommendations depend on appropriate definition of and exchange of information about bulk electric system elements. For RCs, the identification of their "wide area" of responsibility depends on the definition of bulk electric system elements.

In this report, RTBPTF introduces the concept of a "wide-area-view boundary," defined as the network model boundary for the "wide area" as defined by NERC. For reliability coordinators, the wide-area-view boundary defines the minimum required network model needed to support the monitoring requirements for the wide area. This network model should contain all the bulk electric system elements (generators, transmission lines, buses, transformers, breakers, etc.) encompassed by the wide-area-view boundary. Sections 4.1, Model Characteristics, and 4.2, Modeling Practices and Tools, of this report discuss the wide-area-view boundary in more detail.

The wide area that a reliability coordinator must monitor must include the bulk electric system elements in adjacent reliability coordinator footprints that individually (if they were out of service) could impact calculations of SOLs or IROLs beyond a yet-to-be-defined threshold. The wide-area-view boundary must

[24] The Real-Time Tools Survey did not explicitly explore this topic. The RTBPTF perspective is based solely on the professional expertise of the task force members.

include the wide area plus the bulk electric elements in adjacent areas that are collectively needed to ensure accurate analyses of SOLs and IROLs in the wide area.[25]

RTBPTF recommends that NERC and the RROs establish criteria for determining the “wide area boundary” and the RC’s “wide-area view.” RTBPTF recommends that the wide-area-view boundary should be determined based on an impact-based methodology – that is, a process to determine the critical flow and status information from adjacent reliability coordinator areas based on detailed system studies to allow the calculation of IROLs. These uniform formal criteria would clarify the extent and detail required for the “wide area.”

Regarding issues #1 and #2 above, RTBPTF recognizes that the criteria for defining “bulk electric system” and “wide area,” when applied to real-time operations and modeling, will directly affect the number of data required and thus will ultimately affect the content and size of the models used by network applications. RTBPTF’s recommended approach is intended to insure that the required elements of the bulk electric system are appropriately defined and that data for real-time operation and modeling are adequate. See the sidebar *RTBPTF Thoughts on Bulk Electric System, Wide-Area View, and Modeling Requirements* for an explanation of RTBPTF’s view of the interrelationship of issues #1 and #2 and their effect on real-time network models (issue #3 below).

Issue #3: Mandatory Procedures for Specifying Acceptable Reactive Reserves Should be Developed. Reactive reserves monitoring is a documented set of procedures, practices, or guidelines for maintaining awareness of current and near-term reactive reserve capability. Although current NERC standards define acceptable operating (real) reserves, they do not define acceptable reactive reserves. Defining reactive reserves is difficult because they must be evaluated with explicit consideration of network topology and the balance between reactive sources and sinks in local regions within the network. RTBPTF believes that mandatory requirements for real-time tools for reactive reserve monitoring would be highly desirable; however, before such recommendations can be formulated, NERC must define technically justified and feasible-to-implement requirements for determining the appropriate amount and location of acceptable reactive reserves and clarifying how reliability coordinators should monitor these reserves. This issue is explored more fully in Section 3.1, Reserve Monitoring, of this report.

---

[25] That is, RTBPTF recommends that the wide-area-view boundary for RCs be referred to as “minimum boundary conditions based upon a defined set of system conditions, contingencies, and required performance criteria.” Operating Limit Definition Task Force (OLDTF). 2007. *Reliability Criteria and Operating Limits Concepts Reference Document - System Limits - Version 4, Draft 2*. January 29.

Issue #4: Mandatory Procedures for Determining Acceptable Load-Shed Capability Should be Developed. RTBPTF agrees with the *FERC Staff Assessment* that NERC standards do not adequately define requirements for load-shed capability. Thus, although situational awareness requires that operators know how much and how fast they can and must deploy load-shed resources (by means of an appropriate real-time tool), NERC must also make technical progress to define requirements for determining the correct amount, location, and maximum time-to-deploy of load-shed resources. This issue is explored more fully in Section 3.5, Load-Shed Capability, of this report.

Issue #5: External Modeling and Data Exchange Practices Should be Improved by Explicit Reference to the Definition of the Wide-Area-View Boundary. A consistent, uniform set of modeling and data exchange practices, procedures, and standards are needed to support creation and maintenance of accurate external models. RTBPTF recommends that these practices, procedures, and standards follow as a natural outgrowth of the definition of bulk electric system elements that are critical to a particular entity and that, therefore, define the wide-area-view boundary for that entity (per the discussion of issues #1 and #2 above). The complete discussion of this issue and the task force's specific recommendations concerning modeling practices are found in Sections 4.0, Power System Models; 4.1, Model Characteristics; and 4.2, Modeling Practices and Tools, of this report.

RTBPTF recommends that NERC create a new task force to focus specifically on recommending minimum standards for real-time models and data exchange, including:

- Grid change notification
- Model data exchange
- ICCP data exchange (see specific recommendations in Section 1.2, ICCP-Specific Data)
- Supplemental support data exchange (e.g., schematics, maps)
- Non-disclosure agreements

The task force recognizes the work already completed by the NERC Data Exchange Working Group (DEWG) in these areas, which is documented in the ISN Node Responsibilities and Procedures document.[26] The task force considers this work a good starting point for definitive and comprehensive requirements.

Issue #6: Adequate Funding and Staffing for Real-Time Tools and Support Should be Ensured. To ensure adequate monitoring and situational awareness, reliability entities' managers must understand the importance of real-time tools and commit to actively supporting required activities and staff. However, RTBPTF

[26] NERC Data Exchange Working Group (DEWG). 2005. *ISN Node Responsibilities and Procedures*. August 4.

was not able to analyze this issue both because significant differences among organizations made direct comparisons difficult and because this analysis requires expertise beyond that of the task force's members. RTBPTF recommends that OC determine an alternate means for addressing this issue.

Next Steps

RTBPTF emphasizes that this report is only the beginning of NERC and industry efforts to improve reliability through better real-time operating tools and practices. There is still much to do to implement the task force's recommendations for revised standards and operating guidelines and to conduct needed additional analyses.

To initiate the next steps in the process, RTBPTF proposes to finish work on the following activities, which will complete the remainder of the task force's scope of work as assigned by OC:

- Append recommendations for revised standards to the existing Standards Review Forms that are included in the NERC Standards Development Plan: 2007–2009.[27]
- Provide technical support to the standards drafting teams.
- Prioritize areas requiring more analysis.
- Write high-level scopes for the analysis required.

Following completion of these activities, RTBPTF will disband.

As described in the report, RTBPTF also recommends the following additional steps, which are outside the scope assigned to the task force by OC:

- ORS should determine how operating guidelines are to be developed and maintained.
- OC should consider asking the RROs to develop these guidelines as "supplements" to the NERC standards.
- NERC should address the areas in need of more analysis.

Organization of this Report

The remainder of this report is organized as follows:

Five major sections describe the findings, analysis, and task force recommendations for the main subject areas of the Real-Time Tools Survey, and a sixth section details the next steps toward implementing RTBPTF's recommendations:

---

[27] ftp://www.nerc..com/pub/sys/all_updl/standards/sar/FERC_Filing_Volumes_I-II III_Reliability_Standards_Development_Plan_30Nov06.pdf

Section 1.0, Real-Time Data Collection
Section 2.0, Reliability Tools for Situational Awareness
Section 3.0, Situational Awareness Practices
Section 4.0, Power System Modeling
Section 5.0, Support and Maintenance Tools
Section 6.0, Next Steps

Within each section, a general introduction is followed by sections focusing on the main topic areas in that section. Each topical section is structured as follows:

- **Definition** of the specific topic
- **Background** on the specific topic, including blackout investigation findings related to it
- **Summary of Findings** based on the Real-Time Tools Survey responses
- **Recommendations for New Reliability Standards** (if applicable), including new reliability standards or modifications to existing standards, with rationale for each, and major issues to address to clarify interpretation of existing reliability standards in the context of real-time tools usage, practice, and processes that enhance situational awareness
- **Recommendations for Operating Guidelines** (if applicable), including recommendations and corresponding rationale for new operating guidelines, following the Best Practices Task Force conclusion that best practices are "good things to do" and should complement existing NERC reliability standards; operating guidelines are applicable across the industry, but are voluntary, not mandatory
- **Areas Requiring More Analysis** (if applicable), including recommendations that NERC further study a tool or topic about which the Real-Time Tools Survey results were inconclusive
- **Examples of Excellence** (if applicable), a brief notation that RTBPTF identified examples of excellence for the specific topic, which are detailed in Appendix E

The appendices to this report address Real-Time Tools Survey development (Appendix A), participation (Appendix B), analysis (Appendix C), and web links to aggregate survey results (Appendix D). Appendix E, Examples of Excellence, describes practices related to tools and/or operating procedures that exceed minimum requirements of existing standards, are unique to individual organizations, and may not be applicable throughout the industry.

The report also includes a glossary and an acronym list for the reader's convenience.

RTBPTF Thoughts on Bulk Electric System, Wide-Area View, and Modeling Requirements

RTBPTF suggests the following approach to defining bulk electric system elements, the wide-area-view boundary, and modeling requirements:

The list of bulk electric system elements that each reliability coordinator (RC) must maintain shall comprise the bulk electric system elements within the RC's footprint. Call the bulk electric system elements in this list the BES_{RC}.

The wide area that an RC must monitor shall include the BES_{RC} plus the bulk electric system elements in adjacent RC footprints that, individually, if they were out of service, could impact calculations of SOLs or IROLs beyond a yet-to-be-defined threshold. Call the wide area WA and this set of bulk electric system elements in adjacent areas the primary BES_{Adj}.

Thus:

$$WA = BES_{RC} + \text{primary } BES_{Adj}$$

The wide-area view of an RC is simply the information derived from modeling and real-time data made available to the RC operators to fulfill the requirements for monitoring, visualizing, and analyzing the wide area. The wide-area view can extend beyond the wide area.

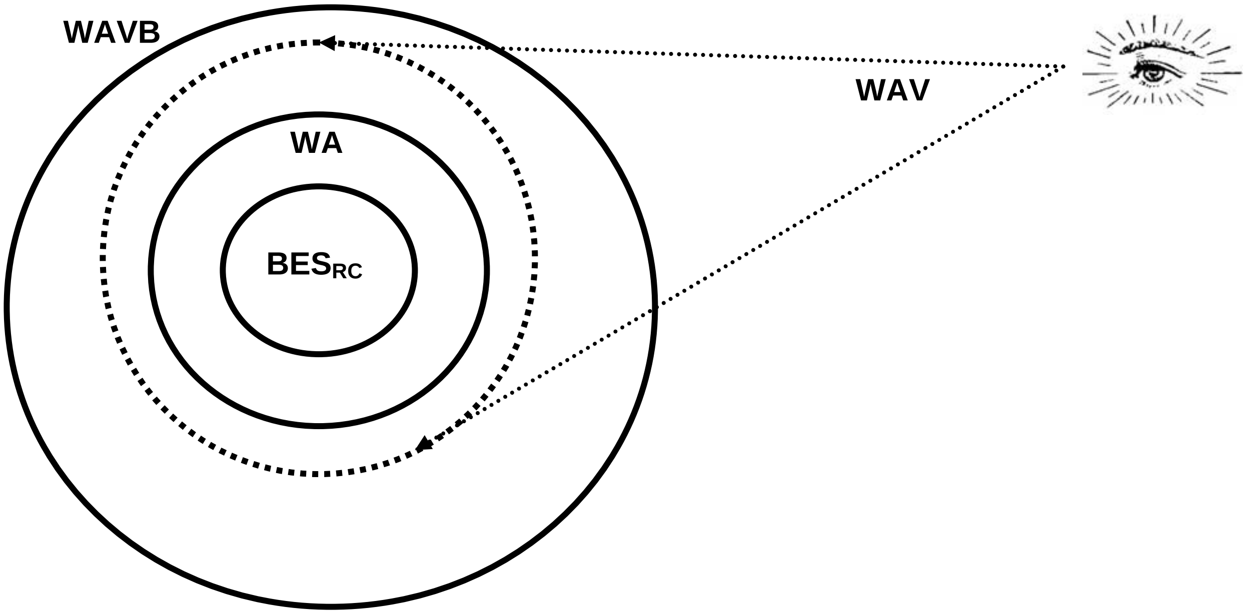
The wide-area-view boundary shall include the wide area plus the bulk electric elements in adjacent areas that are collectively needed to ensure accurate analyses of SOLs and IROLs in the wide area. Call the wide-area-view boundary WAVB and this set of bulk electric system elements the secondary BES_{Adj}.

Thus:

$$WAVB = WA + \text{secondary } BES_{Adj}$$

The internal portion of an RC's real-time network model shall include, at a minimum, the BES_{RC} and any other facilities in the RC footprint needed to ensure accurate analyses of SOLs and IROLs in that RC's footprint.

The external portion of a reliability coordinator's real-time network model shall include, at a minimum, the WAVB.



WAVB
WAV
WA
BES$_{RC}$

Reliability Toolbox Recommendation and Rationale

The RTBPTF recommendation that five real-time tools be required of all reliability coordinators (RCs) and transmission operators (TOPs) addresses tools that are covered in several discrete sections of this report (Section 1.1, Telemetry Data; Section 2.1, Alarm Tools; Section 2.3, Network Topology Processor; Section 2.5, State Estimator; Section 2.6, Contingency Analysis). Therefore, the task force presents the full text of this overarching recommendation separately below, using the same format as for the other recommendations in the specific sections throughout the report.

RTBPTF was charged with defining minimally acceptable capabilities for network analysis and situational awareness tools. By recommending the mandatory tools that make up the Reliability Toolbox as well as specific performance standards and metrics for these tools, RTBPTF believes it has fulfilled this charge to the best of its ability, given the current state of the industry as measured in the Real-Time Tools Survey. All five of the recommended tools enjoy widespread usage in the industry and support the fundamental purpose of maintaining situational awareness and reliable operation of the bulk electric system. The Reliability Toolbox and related performance standards and metrics are technically defensible for today's electric industry, as indicated by the survey results, and will help realize the full potential of these tools. Over time, it may be necessary to reconsider the minimal capabilities of these tools or to consider whether other tools need to be added to the toolbox.

RTBPTF Recommendation

To mandate the Reliability Toolbox, RTBPTF recommends that a new requirement be established under the current Standard TOP-006 (Monitoring System Conditions) to specify the minimum set of monitoring and analysis tools implicitly required by Standard IRO-002 and Standard TOP-008 – that is, to specify the minimum set of tools necessary to monitor the bulk electric system and maintain operator situational awareness. The new standard shall apply to both RCs and TOPs[28]:

PR1. Reliability Monitoring and Analysis Tools (Reliability Toolbox). Each reliability coordinator and transmission operator shall have adequate monitoring and analysis tools to maintain situational awareness for his/her respective areas of responsibility.[29] The following monitoring and analysis tools are mandatory:

[28] Proposed requirements are designated "PR," and proposed measures are designated "PM."

[29] RTBPTF recognizes that differences will arise naturally between TOPs and RCs in their use of the tools. For example, the definition of the wide-area boundary (for RCs) and the "local"

- Alarm tools
- Telemetry data systems
- Network topology processor
- State estimator
- Contingency analysis

RTBPTF recommends the following measure for the requirement stated above:

> PM1. Each reliability coordinator and transmission operator shall have and provide upon request evidence that shall include, but is not limited to, the following:

- Documentation from suppliers
- Operating and support staff training documents and users' guides
- Tool maintenance and support documents
- Logs/records of tool availability and tool output results
- Displays and/or visualization tools that show data from these tools
- Other equivalent evidence to show that it has the monitoring analysis tools in accordance with Requirement PR1 and that the tools are functioning and being used as planned

Rationale

Existing NERC reliability standards require the use of monitoring and analysis tools to aid operators in maintaining situational awareness of the bulk electric system. However, these standards do not explicitly require specific tools and are not globally applicable to all users of such tools. For example, Standard TOP-008 (Response to Transmission Limit Violations) exists, "[t]o ensure Transmission Operators take actions to mitigate SOL and IROL violations."[30] Requirement R4 of this standard states, "[t]he Transmission Operator shall have ***sufficient*** [emphasis added] information and ***analysis tools*** [emphasis added] to determine the cause(s) of SOL violations. This analysis shall be conducted in all operating timeframes. The Transmission Operator shall use the results of these analyses to immediately mitigate the SOL violation." This standard applies only to transmission operators.

Similarly, standard IRO-002 (Reliability Coordination – Facilities) states, "Reliability Coordinators need information, ***tools*** [emphasis added] and other capabilities to perform their responsibilities." Requirement R7 of this standard states, "[e]ach Reliability Coordinator shall have ***adequate analysis tools***

---

transmission system (for TOPs) will have implications for the scope of the network model that each relies upon.

[30] Quotation taken from the purpose statement in section A.3 of NERC Reliability Standard TOP-008-1

[emphasis added] such as state estimation, pre and post-contingency analysis capabilities (thermal, stability, and voltage), and wide-area overview displays." Requirement R9 states, "[e]ach Reliability Coordinator shall control its Reliability Coordinator ***analysis tools*** [emphasis added], including approvals for planned maintenance. Each Reliability Coordinator shall have procedures in place to mitigate the effects of ***analysis tool*** [emphasis added] outages." This standard applies only to reliability coordinators.

RTBPTF believes that Standard TOP-006 is the most appropriate standard in which to incorporate the mandatory tools requirement because this standard is applicable to both RCs and TOPs. In addition, Standard TOP-006 clearly focuses on ensuring that "critical reliability parameters are monitored in real-time."[31] To ensure that critical reliability parameters are monitored in real time, NERC reliability standards must specify a minimum set of tools. The Reliability Toolbox comprises those tools.

RTBPTF believes that the "analysis tools" prescribed by both Standard IRO-002 (Requirement R7) and Standard TOP-008 (Requirement R4) refer to the same set of monitoring and analysis tools even allowing for the natural differences in the use of these tools by TOPs and RCs arising from their different responsibilities as specified by the NERC Functional Model. Locating the Reliability Toolbox requirement in Standard TOP-006, which applies to both reliability coordinators and transmission operators, mandates a uniform minimum set of tools for both RCs and TOPs. It also clarifies and makes specific the term "sufficient information and analysis tools" in Standard TOP-008 (Requirement R4) and the term "adequate analysis tools" in Standard IRO-002 (Requirement R7).

Applicability Statement

Even though the Reliability Toolbox is recommended to be mandatory for only RCs and TOPs, the task force realizes that other entities such as transmission owners and balancing authorities use some or all of these tools as well. In the particular technical sections of this report addressing the individual tools, RTBPTF recommends specific requirements for the use, availability, and performance of these tools, and further recommends in those sections that these requirements apply to all users of the tools. Specifically, any entity not registered in the NERC Functional Model as an RC or a TOP, but that uses any of these tools to support or complement their RC's or TOP's ability to operate the bulk electric system reliably in accordance with formal agreements, contracts, or previously established practices or procedures, shall also be subject to compliance with the specific requirements for the tools.

Section 1.0
Real-Time Data Collection

Introduction

Collecting real-time data on power system status is the first and most elementary step in the complex process of developing the information that electric system operators need to maintain situational awareness. Real-time reliability tools such as the state estimator and contingency analysis can only provide results that accurately represent current and potential reliability problems if these tools have real-time power-flow and voltage values and status data for other elements included in their models. The accuracy of the information that real-time reliability tools provide depends on the accuracy of the data supplied to the tools.

The quality of the results that real-time reliability tools produce is also influenced by the breadth and depth of the portion of the bulk electric system for which real-time data are collected, relative to the breadth and depth of the relevant reliability entity's area of responsibility. Thus, how we define the elements that constitute the bulk electric system is very important for the information that operators reply to for situational awareness.

To assess current industry practice regarding real-time data collection, the Real-Time Data Collection portion of the Real-Time Tools Survey focused on telemetry, ICCP-specific, and miscellaneous data (weather, fault locator, and high-speed sampled data). The survey findings for each type of data are presented in the Sections 1.1-1.3. These sections are summarized below:

- **Section 1.1, Telemetry Data** — This section summarizes the types of real- and near-real-time data collected by telemetry systems for use in EMSs to monitor the bulk electric system. Telemetry data are typically status and analog values that are updated continuously in real or near-real time. These data allow operators to determine, in real- or near-real time, the state of the interconnected bulk electric system. For operators to reliably run the system in a coordinated manner under normal and abnormal conditions, telemetry data systems must function with a high degree of availability. Therefore, tools and practices related to telemetry data availability are important for system reliability and operator situational awareness.

  Section 1.1 also addresses the conversion of real-time data into useful information for operators. The *FERC Staff Assessment* of NERC's proposed reliability standards[1] states:

[1] Federal Energy Regulatory Commission (FERC). 2006. *Staff Preliminary Assessment of the North American Electric Reliability Corporation's Proposed Mandatory Reliability Standards*. www.ferc.gov/indus-act/reliability/standards.asp. Referred to in this document as the *FERC Staff Assessment*.

> … while the requirements identify the data to be gathered, they fail to describe the tools necessary to turn that data into critical reliability parameters, i.e., system capability or contingency analysis, which are required to achieve situational awareness. Reliability Coordinators, Transmission Operators, and Balancing Authorities must be aware of the status of their respective systems, and such situational awareness cannot be obtained by viewing massive amounts of raw data.

RTBPTF agrees that the NERC standards generally fail to describe the tools necessary for monitoring "critical reliability parameters." Section 1.1 gives a snapshot of the types of telemetry data currently being collected throughout the industry, describes the Real-Time Tools Survey findings related to telemetry data, and discusses the tools necessary to comply with NERC standards that require reliability entities to "monitor" specific data and bulk electric system elements and parameters.

Section 1.1 also explores the definition of bulk electric system elements.

- **Section 1.2, ICCP-Specific Data** — ICCP is a standard data-exchange format widely used in the electric utility industry to communicate information among operating entities. The NERC ISN uses ICCP for data exchange among reliability coordinators. Several intra-regional and intra-company networks also use this protocol to provide data to RCs from operating entities within the RC's footprint. Section 1.2 addresses the management of and methodology for ICCP data exchange and examines issues and practices that affect the adequacy, quality, and timeliness of ICCP data supplied to real-time tools that analyze bulk electric system reliability.

- **Section 1.3, Miscellaneous Data** — Miscellaneous data are used by real-time applications/tools that may not be supported by basic SCADA and/or ICCP systems. Section 1.3 addresses: 1) meteorological data, such as from commercial weather services, 2) fault locater data, such as from protective relays that can calculate the distance from the relay location to the location of a transmission-line fault, and 3) high-speed sampled data, such as from sequence-of-event recorders and phasor monitoring units (PMUs).

Significance to the August 14, 2003 Blackout

The U.S.-Canada Power System Outage Task Force analysis of the August 14, 2003[2] blackout identified the failure of the interconnected grid's reliability organizations to provide effective real-time diagnostic support as one cause of the blackout. Specifically, the reliability data that MISO received via the East Central Area Reliability Council (ECAR) data network and other data links were not mapped so that MISO's state estimator could be automatically informed of the status change in key transmission lines.

RTBPTF Recommendations for New Reliability Standards

In Sections 1.1 through 1.3, RTBPTF recommends that several new requirements be added to existing standards:

- Each RC must compile and maintain a list of all bulk electric system elements within its area of responsibility.
- New requirements and measures must be added pertaining to RC monitoring of the bulk electric system.
- Data exchange standards must be developed to address change management and coordination, data access restrictions, naming conventions, joint testing and data checkout, system interoperability, quality codes, and dispute resolution.
- Standards must be developed for data availability, and a process must be developed for trouble resolution and escalation.
- A new requirement must be developed addressing the importance of weather data for situational awareness and real-time operational capabilities. Specifically, operators must be provided dynamically updated real-time and forecasted weather data so that they can readily determine current and near-term weather conditions that might affect how they need to monitor or operate their systems.

[2] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April. Referred to in this document as the *Outage Task Force Final Blackout Report.*

Section 1.1
Telemetry Data

Definition

Telemetry data are status and analog values originating from conventional SCADA/EMS or equivalent systems (telemetry data systems) and are updated continuously in real-time or near-real-time operation. These data may come directly from SCADA system(s) or from direct connection (ICCP, ISN, etc.) to SCADA systems operated by others.

Background

Telemetry data from direct connections to internal systems (i.e., from SCADA/EMS or equivalent systems) and/or direct connections to external systems operated by others (i.e., ICCP data links) allow operators to determine, in real or near-real time, the state of the interconnected bulk electric system. To reliably operate the system in a coordinated manner under normal and abnormal conditions as defined in NERC standards, operators must have telemetry data and corresponding telemetry data systems available. Telemetry data and systems are essential to NERC's mandated real-time monitoring capability; tools and practices related to telemetry data availability are important for system reliability and operator situational awareness.

The *FERC Staff Assessment* of NERC's proposed reliability standards[3] states:

> … while the requirements identify the data to be gathered, they fail to describe the tools necessary to turn that data into critical reliability parameters, i.e., system capability or contingency analysis, which are required to achieve situational awareness. Reliability Coordinators, Transmission Operators, and Balancing Authorities must be aware of the status of their respective systems, and such situational awareness cannot be obtained by viewing massive amounts of raw data.

RTBPTF agrees with the FERC staff conclusions above. NERC standards generally fail to describe the necessary tools for monitoring "critical reliability parameters."

The telemetry data section of the Real-Time Tools Survey was designed to take a snapshot of current availability of certain types of telemetry data throughout the

[3] Federal Energy Regulatory Commission (FERC). 2006. *Staff Preliminary Assessment of the North American Electric Reliability Corporation's Proposed Mandatory Reliability Standards*. www.ferc.gov/indus-act/reliability/standards.asp.

industry. The Real-Time Tools Survey also determined what telemetry data are available from bulk electric system elements currently used by reliability entities. This section of the report describes the survey findings related to telemetry data, discusses the tools necessary to comply with NERC standards that involve use of telemetry data, and presents RTBPTF's recommended requirements for using these tools. This section also discusses issues related to the definition and the interpretation of the term "bulk electric system." RTBPTF reinforces the importance of the resolution of this definition as it affects task force's recommendations. RTBPTF recognizes that entities cannot be expected to use specific tools to monitor the "bulk electric system" without stipulating which components of the bulk electric system are to be monitored or require telemetry data.

Summary of Findings

The subsections below summarize the Real-Time Tools Survey responses regarding telemetry data for generators, transmission lines and transformers, and substation switching devices, as well as telemetry data maintenance and support practices.

Most survey respondents (97 percent, 58 out of 60) indicated that their organizations use telemetry data. An overwhelming majority (96 percent, 54 out of 57) of respondents that have operational telemetry data systems rate the availability of telemetry data as "essential" for situational awareness. This concurrence of opinion is uniform across the types of entities that participated in the survey (RCs, TOPs, BAs). Respondents expressed most concern about the quantity of data available from their systems. For example, one respondent said that "a large network [model] and lack of real time telemetry is one of the biggest issues" with which that respondent deals in "real time network modeling."

Most respondents reported that they receive telemetry data through a combination of direct connection to a SCADA/EMS system (89 percent, 51 out of 57) and/or direct ICCP connections to other utilities/systems (84 percent, 48 out of 57). The applications most commonly reported as using telemetry data were the network topology processor (70 percent, 40 out of 57 respondents), state estimator (77 percent, 44 out of 57), alarm tools (98 percent, 56 out of 57), and visualization tools (81 percent, 46 out of 57).

Generator Telemetry Data

This subsection summarizes the findings for telemetry data from generating units. All respondents reported that they have some form of generator telemetry data available; 95 percent of respondents rated the availability of generator data "essential" to enhancing situational awareness.

Generator Data within Respondent's Area of Responsibility

Respondents were asked to quantify the telemetry data ("all," "most," "some," or "none") they receive from central station generating units within their areas of responsibility. Table 1.1-1 summarizes the responses. The number of respondents selecting the answer listed at the top of a column is given followed by the total number of respondents and the equivalent percentage of respondents (i.e., 36/55=65% indicates that 36 out of 55 respondents or 65 percent of respondents chose this answer). Data are presented in this manner throughout this section.

Type of Generator Telemetry Data	What Telemetry Data do You Receive for Central Station Generating Units Within Your Area of Responsibility?			
	All	Most	Some	None
Total net plant output (MW and Mvar)	36/55=65 %	10/55=18 %	7/55=13 %	2/55=4 %
Unit connection status	36/57=63 %	17/57=30 %	3/57=5 %	1/57=2 %
Unit status (Offline, outage, base load, regulating, etc.)	27/55=49 %	16/55=29 %	9/55=16 %	3/55=5 %
Unit output at the generator terminals (MW and Mvar)	27/56=48 %	23/56=41 %	5/56=9 %	1/56=2 %
Unit-connected station service loads (MW and Mvar)	8/57=14 %	20/57=35 %	19/57=33 %	10/57=18 %
Common station service loads (MW and Mvar)	8/56=14 %	19/56=34 %	22/56=39 %	7/56=13 %
Net unit output at the high side of the step-up transformer (MW and Mvar)	21/57=37 %	18/57=32 %	16/57=28 %	2/57=4 %
Operating Limits (MW)	19/57=33 %	14/57=25 %	11/57=19 %	13/57=23 %
Operating Limits (Mvar)	11/57=19 %	8/57=14 %	8/57=14 %	30/57=53 %
Automatic Voltage Regulator (AVR) Status	3/57=5 %	8/57=14 %	16/57=28 %	30/57=53 %
Stabilizer Status	4/53=8 %	3/53=6 %	7/53=13 %	39/53=74 %
Ramp Rate Capability	10/56=18 %	6/56=11%	14/56=25 %	26/56=46 %
Governor Status	1/53=2 %	1/53=2 %	8/53=15 %	43/53=81 %

Table 1.1-1 — Generator Telemetry Data Within Respondents' Areas of Responsibility — All Respondents

Table 1.1-1 shows that generator total net output (MW and Mvar) and corresponding generator status are the most common forms of generator telemetry data received by respondents within their areas of responsibility. The survey results also reveal that the majority of entities do not receive MW and/or Mvar operating limits. RTBPTF infers that respondents may be using static MW and/or Mvar generator operating limits in lieu of telemetered data. The majority of respondents do not receive other forms of generator telemetry data [i.e., automatic voltage regulator (AVR) status, stabilizer status, etc.] from their telemetry data systems. RC responses to the questions listed in Table 1.1-1 are broken out in Table 1.1-2. The percentages for RC responses are similar to those for all respondents.

Type of Generator Telemetry Data	What Telemetry Data do You Receive for Central Station Generating Units Within Your Area of Responsibility?			
	All	**Most**	**Some**	**None**
Total net plant output (MW and Mvar)	13/17=76 %	2/17=12 %	2/17=12 %	0/17=0 %
Unit connection status	11/18=61 %	5/18=28 %	2/18=11 %	0/18=0 %
Unit status (Offline, outage, base load, regulating, etc.)	9/17=53 %	3/17=18 %	4/17=24 %	1/17=6 %
Unit output at the generator terminals (MW and Mvar)	9/18=50 %	7/18=39 %	2/18=11 %	0/18=0 %
Unit-connected station service loads (MW and Mvar)	1/18=6 %	5/18=28 %	8/18=44 %	4/18=22 %
Common station service loads (MW and Mvar)	1/18=6 %	5/18=28 %	9/18=50 %	3/18=17 %
Net unit output at the high side of the step-up transformer (MW and Mvar)	4/18=22 %	7/18=39 %	7/18=39 %	0/18=0 %
Operating Limits (MW)	6/18=33 %	3/18=17 %	5/18=28 %	4/18=22 %
Operating Limits (Mvar)	4/18=22 %	2/18=11 %	3/18=17 %	9/18=50 %
AVR Status	0/18=0 %	5/18=28 %	9/18=50 %	4/18=22 %
Stabilizer Status	2/17=12 %	2/17=12 %	3/17=18 %	10/17=59 %
Ramp Rate Capability	2/18=11 %	3/18=17 %	4/18=22 %	9/18=50 %
Governor Status	0/17=0 %	0/17=0 %	3/17=18 %	14/17=82 %

Table 1.1-2 — Generator Telemetry Data within Respondents' Areas of Responsibility — RCs only

Generator Data for Adjacent Areas

The survey asked respondents to quantify the telemetry data ("all," "most," "some," or "none") they receive for central station generating units from areas adjacent to the respondents' areas of responsibility. Table 1.1-3 summarizes the responses.

Type of Generator Telemetry Data	What Telemetry Data do You Receive for Central Station Generating Units from Areas Adjacent to Your Area of Responsibility?			
	All	**Most**	**Some**	**None**
Total net plant output (MW and Mvar)	5/55=9 %	4/55=7 %	28/55=51 %	18/55=33 %
Unit connection status	2/56=4 %	5/56=9 %	32/56=57 %	17/56=30 %
Unit status (Offline, outage, base load, regulating, etc.)	1/55=2 %	2/55=4 %	18/55=33 %	34/55=62 %
Unit output at the generator terminals (MW and Mvar)	2/56=4 %	4/56=7 %	28/56=50 %	22/56=39 %
Unit-connected station service loads (MW and Mvar)	0/56=0 %	2/56=4 %	12/56=21 %	42/56=75 %
Common station service loads (MW and Mvar)	0/56=0 %	2/56=4 %	11/56=20 %	43/56=77 %
Net unit output at the high side of the step-up transformer (MW and Mvar)	2/56=4 %	3/56=5 %	28/56=50 %	23/56=41 %
Operating Limits (MW)	1/55=2 %	1/55=2 %	4/55=7 %	49/55=89 %
Operating Limits (Mvar)	1/56=2 %	1/56=2 %	2/56=4 %	52/56=93 %
AVR Status	0/55=0 %	0/55=0 %	2/55=4 %	53/55=96 %
Stabilizer Status	0/55=0 %	0/55=0 %	2/55=4 %	53/55=96 %
Ramp Rate Capability	0/55=0 %	0/55=0 %	3/55=5 %	52/55=95 %
Governor Status	0/55=0 %	0/55=0 %	0/55=0 %	55/55=100 %

Table 1.1-3 — Generator Telemetry Data in Areas Adjacent to Respondents' Areas of Responsibility — All Respondents

Table 1.1-3 shows that the vast majority of respondents do not receive generator telemetry data from areas adjacent to their areas of responsibility. These responses are explained by the lack of specific criteria for the number of adjacent-area telemetry data needed to fulfill monitoring requirements for a "wide-area" view. Table 1.1-4 breaks out RC responses to the questions in Table 1.1-3. The percentages for RC responses are similar to those for all respondents.

Type of Generator Telemetry Data	What Telemetry Data do You Receive for Central Station Generating Units from Areas Adjacent to Your Area of Responsibility?			
	All	**Most**	**Some**	**None**
Total net plant output (MW and Mvar)	2/17=12 %	3/17=18 %	8/17=47 %	4/17=24 %
Unit connection status	2/18=11 %	5/18=28 %	10/18=56 %	1/18=6 %
Unit status (Offline, outage, base load, regulating, etc.)	1/17=6 %	2/17=12 %	8/17=47 %	6/17=35 %
Unit output at the generator terminals (MW and Mvar)	2/18=11 %	4/18=22 %	10/18=56 %	2/18=11 %
Unit-connected station service loads (MW and Mvar)	0/18=0 %	2/18=11 %	5/18=28 %	11/18=61 %
Common station service loads (MW and Mvar)	0/18=0 %	2/18=11 %	6/18=33 %	10/18=56 %
Net unit output at the high side of the step-up transformer (MW and Mvar)	2/18=11%	2/18=11 %	10/18=56 %	4/18=22 %
Operating Limits (MW)	1/18=6 %	1/18=6 %	2/18=11 %	14/18=78 %
Operating Limits (Mvar)	1/18=6 %	1/18=6 %	1/18=6 %	15/18=83 %
AVR Status	0/17=0 %	0/17=0 %	1/17=6 %	16/17=94 %
Stabilizer Status	0/17=0 %	0/17=0 %	1/17=6 %	16/17=94 %
Ramp Rate Capability	0/17=0 %	0/17=0 %	0/17=0 %	17/17=100 %
Governor Status	0/17=0 %	0/17=0 %	0/17=0 %	17/17=100 %

Table 1.1-4 — Generator Telemetry Data in Areas Adjacent to Respondents' Areas of Responsibility — RCs only

Generator Data for Other Units Affecting Respondent's Area of Responsibility

The survey asked respondents to quantify the telemetry data ("all," "most," "some," or "none") they receive for other types of generators that affect their area of responsibility [i.e., independent power producers (IPPs), distributed generation]. Table 1.1-5 summarizes the responses. The table shows that the majority of respondents do not receive generator telemetry data from other units that may affect their areas of responsibility. Note that IPPs may have a significant impact on an entity's area of responsibility.

Type of Generator Telemetry Data	Do You Receive Real-Time Data for Other Units Affecting Your Area of Responsibility?			
	All	Most	Some	None
IPPs	21/55=38 %	10/55=18 %	11/55=20 %	13/55=24 %
Distributed generation at cogeneration or customer locations	6/57=11 %	10/57=18 %	18/57=32 %	23/57=40 %
Customer loads participating in generation ancillary service	6/55=11 %	6/55=11 %	4/55=7 %	39/55=71 %
Generating plants beyond adjacent areas of your responsibility	2/57=4 %	5/57=9 %	13/57=23 %	7/57=65 %

Table 1.1-5 — Other Types of Generator Telemetry Data from Areas Adjacent to Respondents' Areas of Responsibility

Special or Calculated Generator Data

The survey asked respondents to quantify the telemetry data ("all," "most," "some," or "none") received for any special, real-time calculation for generating units in or adjacent to their areas of responsibility. Table 1.1-6 summarizes the responses Respondents do not commonly receive these types of data.

Special Generator Telemetry Data Type	Do You Use Any Special, Real-Time Calculation for Generating Units In or Adjacent to Your Area of Responsibility?			
	All	Most	Some	None
Substitute for any values at generating units not available by SCADA	1/51=2 %	1/51=2 %	19/51=37 %	30/51=59 %
Supplemental available data (such as reserve levels, hours of fuel, etc.)	3/53=6 %	1/53=2 %	11/53=21 %	38/53=72 %

Table 1.1-6 — Generator Telemetry Data for Special Real-Time Calculations In or Adjacent to Respondents' Areas of Responsibility

Transmission-Line Telemetry Data

This subsection summarizes survey findings regarding telemetry data for transmission lines. All respondents have some form of transmission-line telemetry data available, and 96 percent rated availability of transmission-line data as "essential" for enhancing situational awareness.

Transmission-Line Data within Respondents' Areas of Responsibility

The survey asked respondents to quantify the telemetry data ("all," "most," "some," or "none") they receive for transmission lines [345-765 kilovolt (kV)] within their areas of responsibility. Table 1.1-7 summarizes the responses.

Type of Transmission-Line Telemetry Data	What Telemetry Data do You Receive for Transmission Lines (345-765 kV) Within Your Area of Responsibility?			
	All	Most	Some	None
MW and Mvar flow on at least one end	38/52=73 %	5/52=10 %	1/52=2 %	8/52=15 %
MW and Mvar flow on both ends	31/53=58 %	13/53=25 %	0/53=0 %	9/53=17 %
Current flow magnitude (Amperes) at either end	8/51=16 %	6/51=12 %	7/51=14 %	30/51=59 %
Current flow phase angle (degrees) at either end	0/51=0 %	2/51=4 %	5/51=10 %	44/51=86 %
Megavoltamperes (MVA) flow at either end	4/52=8 %	5/52=10 %	3/52=6 %	40/52=77 %
Real-time operating limits determined by substation equipment/systems	10/52=19 %	1/52=2 %	5/52=10 %	36/52=69 %
Line connection status	37/52=71 %	6/52=12 %	1/52=2 %	8/52=15 %
Line availability status (Tagged out, damaged, grounded, etc.)	18/51=35 %	1/51=2 %	4/51=8 %	28/51=55 %
kV on at least one end	36/52=69 %	7/52=13 %	1/52=2 %	8/52=15 %
kV on both ends	27/52=52 %	11/52=21 %	4/52=8 %	10/52=19 %

Table 1.1-7 — Telemetry Data for Transmission Lines (345-765 kV) Within Respondents' Areas of Responsibility — All Respondents

Table 1.1-7 shows that MW and Mvar flows, line connection status, and kV on at least one end are the most common forms of transmission-line telemetry data that respondents receive for 345 to 765-kV transmission lines within their areas of responsibility. Respondents report that their telemetry data systems provide either "all" or "most" of these data. The survey results also reveal that the majority of respondents do not receive MW and/or Mvar operating limit data. RTBPTF infers that respondents may be using static MW and/or Mvar transmission-line operating limits in lieu of telemetered data. The majority of respondents do not receive other forms of transmission-line telemetry data (i.e., current flow magnitude, phase angle measurements) within their areas of responsibility. Table 1.1-8 summarizes responses to this survey question from RCs only regarding transmission-line data. The percentages for reliability coordinators' responses are similar to those for all respondents.

Type of Transmission-Line Telemetry Data	What Telemetry Data do You Receive for Transmission Lines (345-765 kV) Within Your Area of Responsibility?			
	All	Most	Some	None
MW and Mvar flow on at least one end	13/17=76 %	3/17=18 %	0/17=0 %	1/17=6 %
MW and Mvar flow on both ends	10/17=59 %	7/17=41 %	0/17=0 %	0/17=0 %
Current flow magnitude (Amperes) at either end	4/16=25 %	0/16=0 %	3/16=19 %	9/16=56 %
Current flow phase angle (degrees) at either end	0/16=0 %	0/16=0 %	2/16=13 %	14/16=88 %
MVA flow at either end	0/17=0 %	2/17=12 %	2/17=12 %	13/17=76 %
Real-time operating limits determined by substation equipment/systems	4/17=24 %	1/17=6 %	4/17=24 %	8/17=47 %
Line connection status	12/17=71 %	5/17=29 %	0/17=0 %	0/17=0 %
Line availability status (tagged out, damaged, grounded, etc.)	6/16=38 %	0/16=0 %	2/16=13 %	8/16=50 %
kV on at least one end	10/17=59 %	5/17=29 %	1/17=6 %	1/17=6 %
kV on both ends	8/17=47 %	5/17=29 %	3/17=18 %	1/17=6 %

Table 1.1-8 — Telemetry Data for Transmission Lines (345-765 kV) Within Respondents' Areas of Responsibility — RCs only

The survey asked respondents to quantify telemetry data (“all,” “most,” “some,” or “none”) they receive for transmission lines (100 to 230 kV) within their areas of responsibility. Table 1.1-9 summarizes the responses. For 100- to 230-kV voltage transmission lines, telemetry data for MW and Mvar flows, line connection status, and kV on at least one end are the most common telemetry data that respondents receive within their areas of responsibility although these data are not as common as data for 345- to 765-kV transmission lines. For 345- to 765-kV transmission lines, the majority of respondents do not receive data on MW and/or Mvar operating limits. RTBPTF infers that entities may be using static MW and/or Mvar transmission line operating limits in lieu of telemetered data.

Type of Transmission-Line Telemetry Data	What Telemetry Data do You Receive for Transmission Lines (100-230 kV) Within Your Area of Responsibility?			
	All	Most	Some	None
MW and Mvar flow on at least one end	29/56=52 %	24/56=43 %	3/56=5 %	0/56=0 %
MW and Mvar flow on both ends	13/57=23 %	32/57=56 %	12/57=21 %	0/57=0 %
Current flow magnitude (Amperes) at either end	9/55=16 %	10/55=18 %	11/55=20 %	25/55=45 %
Current flow phase angle (degrees) at either end	0/54=0 %	0/54=0 %	8/54=15 %	46/54=85 %
MVA flow at either end	12/55=22 %	5/55=9 %	1/55=2 %	37/55=67 %

kV on at least one end	32/55=58 %	19/55=35 %	4/55=7 %	0/55=0 %
kV on both ends	13/57=23 %	30/57=53 %	13/57=23 %	1/57=2 %

Table 1.1-9 — Telemetry Data for 100- to 230-kV Transmission Lines Within Respondents' Areas of Responsibility

Respondents were also asked to quantify telemetry data ("all," "most," "some," or "none") they receive for transmission lines less than 100 kV within their areas of responsibility. Table 1.1-10 summarizes the responses. The majority of respondents do not receive telemetry data for less-than-100-kV transmission lines within their areas of responsibility.

Type of Transmission-Line Telemetry Data	What Telemetry Data do You Receive for Transmission Lines (<100 kV) Within Your Area of Responsibility?			
	All	Most	Some	None
MW and Mvar flow on at least one end	16/56=29 %	24/56=43 %	14/56=25 %	2/56=4 %
MW and Mvar flow on both ends	10/57=18 %	17/57=30 %	25/57=44 %	5/57=9 %
Current flow magnitude (Amperes) at either end	5/55=9 %	14/55=25 %	8/55=15 %	28/55=51 %

Table 1.1-10 — Telemetry Data for less-than-100-kV Transmission Lines Within Respondents' Areas of Responsibility

Transmission-Line Data for Adjacent Areas

The survey asked respondents to quantify telemetry data ("all," "most," "some," or "none") they receive for transmission lines (345 to 765 kV) in areas adjacent to their areas of responsibility. Table 1.1-11 summarizes the responses.

Type of Transmission-Line Telemetry Data	What Telemetry Data do You Receive for Transmission Lines (345-765 kV) From Areas Adjacent to Your Area of Responsibility?			
	All	Most	Some	None
MW and Mvar flow on at least one end	10/56=18 %	12/56=21 %	26/56=46 %	8/56=14 %
MW and Mvar flow on both ends	5/56=9 %	3/56=5 %	30/56=54 %	18/56=32 %
Current flow magnitude (Amperes) at either end	3/54=6 %	1/54=2 %	11/54=20 %	39/54=72 %
Current flow phase angle (degrees) at either end	0/54=0 %	0/54=0 %	2/54=4 %	52/54=96 %
MVA flow at either end	1/55=2 %	2/55=4 %	8/55=15 %	44/55=80 %
Real-time operating limits determined by substation equipment/systems	3/55=5 %	0/55=0 %	4/55=7 %	48/55=87 %
Line connection status	10/56=18 %	6/56=11 %	24/56=43 %	16/56=29 %
Line availability status (Tagged out, damaged, grounded, etc.)	5/56=9 %	1/56=2 %	5/56=9 %	45/56=80 %
kV on at least one end	9/56=16 %	9/56=16 %	26/56=46 %	12/56=21 %
kV on both ends	4/56=7 %	4/56=7 %	23/56=41 %	25/56=45 %

Table 1.1-11 — Telemetry Data for Transmission Lines (345-765 kV) in Areas Adjacent to Respondents' Areas of Responsibility — All Respondents

Table 1.1-11 shows that the majority of respondents do not receive transmission-line telemetry data from adjacent areas. This may be explained by the lack of specific criteria for the adjacent-area telemetry data needed to fulfill monitoring requirements for "wide-area" view. Table 1.1-12 shows responses for RCs only regarding transmission-line telemetry data from adjacent areas. The percentages for RCs' responses are similar to those for all respondents.

Type of Transmission-Line Telemetry Data	What Telemetry Data do You Receive for Transmission Lines (345-765 kV) from Areas Adjacent to Your Area of Responsibility?			
	All	Most	Some	None
MW and Mvar flow on at least one end	6/18=33 %	9/18=50 %	3/18=17 %	0/18=0 %
MW and Mvar flow on both ends	4/18=22 %	7/18=39 %	7/18=39 %	0/18=0 %
Current flow magnitude (Amperes) at either end	1/17=6 %	3/17=18 %	3/17=18 %	10/17=59 %
Current flow phase angle (degrees) at either end	0/17=0 %	0/17=0 %	0/17=0 %	17/17=100 %
MVA flow at either end	1/18=6 %	2/18=11 %	1/18=6 %	14/18=78 %
Real-time operating limits determined by substation equipment/systems	2/18=11 %	4/18=22 %	5/18=28 %	7/18=39 %
Line connection status	8/18=44 %	6/18=33 %	3/18=17 %	1/18=6 %
Line availability status (Tagged out, damaged, grounded, etc.)	4/16=25 %	3/16=19 %	1/16=6 %	8/16=50 %
KV on at least one end	8/18=44 %	6/18=33 %	4/18=22 %	0/18=0 %
KV on both ends	4/18=22 %	5/18=28 %	8/18=44 %	1/18=6 %

Table 1.1-12 — Telemetry Data for Transmission Lines (345-765 kV) from Adjacent Areas — RCs Only

Respondents were asked to quantify telemetry data they receive (“all,” “most,” “some,” or “none”) for transmission lines (100-230 kV) from areas adjacent to their areas of responsibility. Table 1.1-13 summarizes the responses. The majority of respondents do not receive telemetry data for transmission lines (100-230 kV) in adjacent areas.

Type of Transmission-Line Telemetry Data	What Telemetry Data do You Receive for Transmission Lines (100-230 kV) from Areas Adjacent to Your Area of Responsibility?			
	All	Most	Some	None
MW and Mvar flow on at least one end	7/55=13 %	7/55=13 %	34/55=62 %	7/55=13 %
MW and Mvar flow on both ends	3/55=5 %	5/55=9 %	31/55=56 %	16/55=29 %
Current flow magnitude (Amperes) at either end	2/52=4 %	0/52=0 %	11/52=21 %	39/52=75 %
Current flow phase angle (degrees) at either end	0/52=0 %	0/52=0 %	1/52=2 %	51/52=98 %
MVA flow at either end	2/52=4 %	0/52=0 %	9/52=17 %	41/52=79 %
Real-time operating limits determined by substation equipment/systems	1/53=2 %	1/53=2 %	6/53=11 %	45/53=85 %
Line connection status	9/54=17 %	3/54=6 %	30/54=56 %	12/54=22 %
Line availability status (Tagged out, damaged, grounded, etc.)	3/54=6 %	2/54=4 %	6/54=11 %	43/54=80 %
KV on at least one end	6/54=11 %	4/54=7 %	32/54=59 %	12/54=22 %
KV on both ends	2/55=4 %	5/55=9 %	29/55=53 %	19/55=35 %

Table 1.1-13 — Telemetry Data for Transmission Lines (100-230 kV) from Areas Adjacent to Respondents' Areas of Responsibility

Respondents were asked to quantify telemetry data they receive ("all," "most," "some," or "none") for transmission lines (less than 100 kV) from areas adjacent to their areas of responsibility. Table 1.1-14 summarizes the responses. Most respondents received no telemetry data for transmission lines less than 100 kV in adjacent areas.

Type of Transmission-Line Telemetry Data	What Telemetry Data do You Receive for Transmission Lines (<100 kV) from Areas Adjacent to Your Area of Responsibility?			
	All	Most	Some	None
MW and Mvar flow on at least one end	0/55=0 %	2/55=4 %	24/55=44 %	29/55=53 %
MW and Mvar flow on both ends	0/55=0 %	1/55=2 %	17/55=31 %	37/55=67 %
Current flow magnitude (Amperes) at either end	0/53=0 %	0/53=0 %	4/53=8 %	49/53=92 %
Current flow phase angle (degrees) at either end	0/53=0 %	0/53=0 %	0/53=0 %	53/53=100 %
MVA flow at either end	0/53=0 %	0/53=0 %	2/53=4 %	51/53=96 %

KV on both ends	0/54=0 %	0/54=0 %	19/54=35 %	35/54=65 %

Table 1.1-14 — Telemetry Data for Transmission Lines (less than 100 kV) from Areas Adjacent to Respondents' Areas of Responsibility

Transmission-Line Data — Special or Calculated

The survey asked respondents to quantify telemetry data they receive ("all," "most," "some," or "none") for any special, real-time calculation for transmission lines in or adjacent to their areas of responsibility. Table 1.1-15 summarizes the responses. The majority of respondents do not receive special or calculated transmission-line telemetry data.

Special Transmission-Line Telemetry Data Type	Do You Use Any Special, Real-Time Calculation for Transmission Lines in or Adjacent to Your Area of Responsibility?			
	All	Most	Some	None
Special substitution for any values on lines not available by SCADA	7/55=13 %	1/55=2 %	19/55=35 %	28/55=51 %
Terminal angular separation (degrees)	2/53=4 %	0/53=0 %	4/53=8 %	47/53=89 %
Supplemental available data (such as line temperature, time in overload, etc)	1/52=2 %	2/52=4 %	5/52=10 %	44/52=85 %

Table 1.1-15 — Telemetry Data for Special, Real-Time Calculations for Transmission Lines In or Adjacent to Respondents' Areas of Responsibility

Transmission Transformer Telemetry Data

This subsection summarizes findings for transmission transformer telemetry data. All respondents have some form of transmission transformer telemetry data available; 85 percent rated the availability of transmission transformer telemetry data as "essential" for enhancing their situational awareness.

Transmission Transformer Data within Respondents' Areas of Responsibility

The survey asked respondents to quantify telemetry data they receive ("all," "most," "some," or "none") for transmission transformers (at various voltage levels) within their areas of responsibility. Table 1.1-16, Table 1.1-17, and Table 1.1-18 summarize the responses. It is interesting to note that the majority of respondents do not receive telemetry data for transmission transformers within their areas of responsibility even in the highest voltage range (i.e., 345-765 kV). As the voltage level decreases, even fewer telemetry data are received.

Table 1.1-21 — Telemetry Data for Transmission Transformers (100-230 kV) from Areas Adjacent to Respondents' Areas of Responsibility

Substation Switching Device Telemetry Data

This subsection summarizes findings for substation switching device telemetry data. These data are gathered from substation circuit breakers and disconnect switches. All survey respondents have some form of substation switching device telemetry data available; 93 percent rate the availability of substation switching device data "essential" for enhancing their situational awareness.

Substation Switching Device Data within Respondents' Areas of Responsibility

Respondents were asked to quantify the telemetry data they receive ("all," "most," "some," or "none") for substation circuit breakers and disconnect switches (at various voltage levels) within their areas of responsibility. Table 1.1-22, Table 1.1-23, and Table 1.1-24 summarize the responses. Substation circuit breaker status data are the most commonly received.

Type of Substation Switching Device Telemetry Data	What Telemetry Data do You Receive for Substation Switching Devices (345-765 kV) Within Your Area of Responsibility?			
	All	Most	Some	None
Circuit breaker status	41/51=80 %	4/51=8 %	0/51=0 %	6/51=12 %
Breaker disconnect switch status	11/51=22 %	9/51=18 %	14/51=27 %	17/51=33 %

Substation Switching Device Data for Adjacent Areas

The survey asked respondents to quantify telemetry data they receive ("all," "most," "some," or "none") for substation circuit breakers and disconnect switches (at various voltage levels) from areas adjacent to their areas of responsibility. Table 1.1-25, Table 1.1-26, and Table 1.1-27 summarize the responses. The majority of respondents do not receive telemetry data for substation switching devices in adjacent areas.

Type of Substation Switching Device Telemetry Data	What Telemetry Data do You Receive for Substation Switching Devices (345-765 kV) in Areas Adjacent to Your Area of Responsibility?			
	All	Most	Some	None
Circuit breaker status	7/53=13 %	7/53=13 %	27/53=51 %	12/53=23 %
Breaker disconnect switch status	1/52=2 %	4/52=8 %	13/52=25 %	34/52=65 %

Telemetry Data Maintenance and Support Practices

The Real-Time Tools Survey includes questions pertaining to routine, regular activities that ensure the quality and integrity of telemetered data. A majority of respondents (66 percent) perform maintenance activities related to the availability of their telemetry data. Respondents that have some form of maintenance activity consider it to be "essential" (56 percent) or "desirable" (42 percent) for situational awareness. A majority (78 percent) of respondents that perform maintenance have processes or procedures for telemetry personnel to perform regular, manual checks of the data. A majority (78 percent) of the respondents perform maintenance activities "as needed."

Fifty percent or more of respondents who use testing/debugging/diagnostic tools to check telemetry data employ the following tools:

- Remote terminal unit (RTU) test set (RTU simulator)
- Data communication network analyzer
- EMS host communication traffic viewer/analyzer
- Communication error reporting on EMS
- Quality code processing
- On-line diagnostics (running in real time)

The survey includes questions about tools/processes to make support personnel aware when telemetered data are erroneous or not available. A majority of respondents (94 percent) notify the personnel responsible for the telemetered data if the data are erroneous or are not received. A majority (78 percent) consider these notifications "essential" for situational awareness. The most common notification method is an alarm; the operator receiving the alarm calls support personnel to address the problem. Respondents also have provisions for personnel to remotely support operators when telemetry data issues arise.

Recommendations for New Reliability Standards

Telemetry data are essential for operators to monitor the status of bulk electric system elements and parameters. Telemetry data are typically the main input to other applications/tools (i.e., SCADA applications, alarm tools, state estimator) used to monitor bulk electric system elements and parameters. The following discussions support RTBPTF's major recommendation to make telemetry data systems mandatory (see the Reliability Toolbox Recommendation and Rationale section, which describes the recommended mandatory tools, including telemetry data systems, for RCs and TOPs).

RTBPTF also recognizes that entities cannot be expected to use specific tools to monitor the bulk electric system without stipulating which components of the system are to be monitored or require telemetry data, so the following subsections discuss this issue. Where appropriate, RTBPTF recommends modifications to existing standards.

Recommendation – S1

Mandate the following reliability tools as mandatory monitoring and analysis tools

- Alarm Tools
- Telemetry Data Systems
- Network Topology Processor
- State Estimator
- Contingency Analysis

Telemetry data systems: mandatory monitoring and analysis tool

Telemetry data systems update status and analog values from conventional SCADA/EMSs and from the SCADA/EMSs of others (via ICCP, ISN, etc.) continuously in real or near-real time. Telemetry data systems are the primary sources of information that directly and indirectly (by supporting other applications) provide situational awareness to operators. RTBPTF believes that telemetry data systems are essential for operators to monitor and maintain the reliability of the bulk electric system. Existing NERC reliability standards implicitly assume the use of telemetry data systems to aid RCs and TOPs in maintaining situational awareness for the bulk electric system. Specifying telemetry data systems as part of the Reliability Toolbox[4] eliminates the vagueness in the current NERC reliability standards and clarifies that telemetry data systems, as defined, are mandatory.

Telemetry data system availability

Because RTBPTF recommends that telemetry data systems be mandatory tools for maintaining bulk electric system situational awareness, these tools must be highly redundant and available. Thus, RTBPTF also recommends requiring that operators be aware of the availability status of these tools. RTBPTF recommendation presented in Section 5.4, Critical Applications Monitoring, addresses telemetry data system availability. RTBPTF believes that the recommendations in Section 5.4 are sufficient to maintain operators' situational awareness of the availability of this critical monitoring tool.

"Bulk Electric System" definition

The term "bulk electric system" appears throughout numerous existing NERC reliability standards. The NERC Glossary defines "bulk electric system" as follows: "[a]s defined by the Regional Reliability Organization, the electrical generation of resources, transmission lines, interconnections with neighboring systems, and associated equipment, generally operated at voltages 100 kV or higher. Radial transmission facilities serving only load with one transmission

[4] See the Reliability Toolbox Recommendation and Rationale section.

source are generally not included in this definition." However, section 215(a)(1) of the Federal Powers Act defines the bulk power system as "[f]acilities and control systems necessary for operating an interconnected electric energy transmission network (or any portion thereof), and electric energy from generating facilities needed to maintain transmission system reliability. The term does not include facilities used in the local distribution of electric energy."

The *FERC Staff Assessment*[5] notes that "[t]he FPA and NERC definitions obviously differ. The standards currently are applied only to the Bulk Electric System as defined by each Region. However, section 215(a)(3) of the FPA defines Reliability Standard as a requirement approved by the Commission to provide for reliable operation of the Bulk-Power System. The term Bulk Electric System does not appear to include all the system components from all non-distribution voltage levels, control systems, and electric energy from all generating facilities needed to maintain transmission system reliability included in the definition of Bulk-Power System."

The *FERC Staff Assessment* states, "[e]lements of numerous standards appear to be subject to multiple interpretations, especially with regard to the specificity of the standards' requirements, measurability, and degrees of compliance. This ambiguity also extends to the differing definitions for the Bulk-Power System and the Bulk Electric System." The *FERC Staff Assessment* further notes, "[w]hen the task of defining the Bulk Electric System is delegated to each RRO, the result could be conflicting multiple definitions that subject different facilities to, or exclude different facilities from, the requirements of the standards."

Recommendation – I1

Define what constitutes bulk electric system elements and parameters as they relate to existing standards.

RTBPTF Recommendation

RTBPTF recommends that NERC define what constitutes bulk electric system elements and parameters as they relate to existing standards. Specifically, NERC needs to resolve whether the bulk electric system should continue to be defined by regional reliability organizations (RROs) or whether a single NERC definition should be adopted. In either case, the defined criteria shall be applied to all of the NERC reliability standards. The criteria for classifying bulk electric system elements and parameters need to be clearly and unambiguously stated

[5] Federal Energy Regulatory Commission (FERC). 2006. *Staff Preliminary Assessment of the North American Electric Reliability Corporation's Proposed Mandatory Reliability Standards*. www.ferc.gov/indus-act/reliability/standards.asp.

so that reliability entities can comply fully with reliability standards that refer to the bulk electric system.

Rationale

The bulk electric system definition is particularly important for numerous existing NERC standards that specify and require "monitoring" by reliability entities of specific data and bulk electric system elements and parameters. The standards have common, well-established requirements but, in most cases, are not specific about how reliability entities are to measure and/or comply with the monitoring requirements.

The survey results quantified the number of telemetry data currently available for elements at different voltage levels (100 kV and above). Not all telemetry data for these elements are currently available. This is an interesting finding because the 100-kV level is explicitly identified in the current definition of the bulk electric system. The survey results illustrate that respondents' telemetry data practices are not uniform. The results also suggest that design standards (related to telemetry measurements for transmission facilities) are typically developed by transmission operators for their own use. These practices and standards do not appear to be completely supportive of NERC-mandated requirements for monitoring of the bulk electric system elements by reliability entities.

Monitoring standards/requirements

The existing NERC standards listed below require that reliability entities monitor bulk electric system elements and parameters. In RTBPTF's opinion, the word "monitor" does not imply viewing large amounts of raw telemetered data but rather viewing data in a manner and format that allows operators to rapidly judge the state of the bulk electric system and take corrective action when necessary. Reliability entities could monitor bulk electric system elements and parameters directly using tools such as state estimators (with defined measurement-observability requirements) or other indirect approaches such as calculated points based on existing telemetry data (i.e., calculated MVA based on MW and Mvar telemetered data). However, all such monitoring approaches depend on information obtained from processing raw data. Processing is necessary to use telemetry data for monitoring; this understanding forms the context for the discussions of monitoring standards below.

Where noted below, RTBPTF recommends additions/modifications to standards and their corresponding requirements and/or measures. The discussion emphasizes use of available tools to aid reliability entities in monitoring bulk electric system elements and parameters. The recommendations below assume that the definition of the term "bulk electric system" is clarified per the RTBPTF recommendation above.

1. NERC Reliability Standard TOP-005, Operational Reliability Information

The purpose of TOP-005 is "[t]o ensure reliability entities have the operating data needed to monitor system conditions within their areas." This standard specifies what data are needed by reliability entities to monitor the bulk power system. Requirement R1 states, "[e]ach Transmission Operator and Balancing Authority shall provide its Reliability Coordinator with the operating data that the Reliability Coordinator requires to perform operational reliability assessments and to coordinate reliable operations within the Reliability Coordinator Area… [e]ach Reliability Coordinator shall identify the data requirements from the list [specified] in [the]…'Electric System Reliability Data' and any additional operating information requirements relating to operation of the bulk power system within the Reliability Coordinator Area."

RTBPTF Recommendations

The use of telemetry data systems is ubiquitous in the industry. Moreover, improvements in data communication technologies have dramatically increased the update frequency that is now common to all systems. The "Electric System Reliability Data" appendix[6] specifies the data required from each RC's TOPs and BAs to perform operational reliability assessments and to coordinate reliable operations within the RC's area. The "Electric System Reliability Data" appendix also lists the types of data that RCs, TOPs, and BAs are expected to provide to and share with each other.

In general, RTBPTF believes that the update frequency for certain types of reliability data specified in the "Electric System Reliability Data" appendix of at least every 10 minutes is not sufficient to monitor critical reliability parameters in real time. RTBPTF recommends changing the update frequency requirement to every 10 seconds. RTBPTF believes that most commercially available telemetry data systems used industry-wide are capable of supporting a 10-second update frequency.

The specific recommendations for modifications to the items listed in the "Electric System Reliability Data" appendix are explained in Table 1.1-28 (see "Discussion" column).

Rationale

Table 1.1-28 lists the contents of the "Electric System Reliability Data" appendix; the "Discussion" column contains RTBPTF's recommendations for modifications to items listed in the appendix together with the corresponding rationale.

[6] This is an appendix to Standard TOP-005.

<table>
<tr><th>Type of Reliability Data</th><th>Discussion</th></tr>
<tr><td>1.1. Transmission data. Transmission data for all Interconnections plus all other facilities considered key, from a reliability standpoint:
1.1.1 Status
1.1.2 MW or ampere loadings
1.1.3 MVA capability
1.1.4 Transformer tap and phase angle settings
1.1.5 Key voltages</td><td><u>Recommendations:</u>
1. RTBPTF recommends revising item 1.1.2 “MW or ampere loadings” to read: “MW, Mvar, and ampere loadings.”
2. RTBPTF recommends that the following transmission data specified in item 1.1 of the “Electric System Reliability Data” appendix (with the exception of MVA capability data) shall be provided and updated at least every 10 seconds:
• Status
• MW or ampere loadings
• Transformer tap and phase angle settings
• Key voltages
3. RTBPTF recommends that MVA capability data shall be “provided upon every update” or “as soon as available.”
<u>Rationale:</u>
1. For completeness, the “Mvar loadings” for transmission data should be part of item 1.1.2 of the “Electric Systems Reliability Data” appendix. Mvar data are essential to ascertain proper loadings of transmission equipment.
2. RTBPTF believes that an update frequency of at least every 10 minutes is not sufficient for responsible entities to have the most current data to monitor critical reliability parameters in real time. Transmission data may be needed by other applications such as the state estimator and/or contingency analysis to detect actual or potential SOL/IROL violations. More frequent updates of transmission data are needed to provide better analysis for operators.
3. RTBPTF believes that the MVA capability data (and the corresponding update frequency for the data) are addressed by Standard TOP-002, Requirement 11, which states, “[t]he Transmission Operator shall perform seasonal, next-day, and current-day Bulk Electric System studies to determine SOLs… The Transmission Operator shall update these Bulk Electric System studies as necessary to reflect current system conditions; and shall make the results of Bulk Electric System studies available to the Transmission Operators, Balancing Authorities (subject confidentiality requirements), and to its Reliability Coordinator.” It is not necessary to provide the MVA capability information unless new updates are available.</td></tr>
</table>

Type of Reliability Data	Discussion
1.2. Generator data 1.2.1 Status 1.2.2 MW and Mvar capability 1.2.3 MW and Mvar net output 1.2.4 Status of automatic voltage control facilities	Recommendations: 1. RTBPTF recommends that the following generator data specified in item 1.2 of the "Electric System Reliability Data" appendix (with the exception of MW and Mvar capability data) shall be provided and updated at least every 10 seconds: • Status • MW and Mvar net output • Status of automatic voltage control facilities 2. RTBPTF recommends that MW and Mvar capability data shall be "provided upon every update" or "as soon as available." Rationale: 1. RTBPTF believes that update frequency of at least every 10 minutes is not sufficient for responsible entities to have the most current data to monitor critical reliability parameters in real time. Generator data may be needed by other applications such as the state estimator and/or contingency analysis to detect actual or potential SOL/IROL violations. More frequent update of generator data is needed to provide better analysis for operators. 2. The generator MW and Mvar capability data (and the corresponding update frequency for the data) are addressed by Standard TOP-002, Requirement 11, which states, "[t]he Transmission Operator shall perform seasonal, next-day, and current-day Bulk Electric System studies to determine SOLs… The Transmission Operator shall update these Bulk Electric System studies as necessary to reflect current system conditions [i.e., generator capability]; and shall make the results of Bulk Electric System studies available to the Transmission Operators, Balancing Authorities (subject confidentiality requirements), and to its Reliability Coordinator." It is not necessary to provide the generator MW and Mvar capability information unless new updates are available.
1.3. Operating reserve 1.3.1 MW reserve available within ten minutes	Recommendation: 1. RTBPTF recommends that the generator data specified in item 1.3 of the "Electric System Reliability Data" appendix shall be provided at least every 10 seconds. Rationale: 1. RTBPTF believes that update frequency of at least every 10 minutes is not sufficient for responsible entities to have the most current data to monitor critical reliability parameters (i.e., operating reserves) in real time.

Type of Reliability Data	Discussion
1.4. Balancing Authority demand 1.4.1 Instantaneous	Recommendation: 1. RTBPTF recommends that the balancing authority demand data specified in item 1.4 of the "Electric System Reliability Data" appendix shall be provided at least every 10 seconds. Rationale: 1. RTBPTF believes that update frequency of at least every 10 minutes is not sufficient for responsible entities to have the most current operating data to monitor critical reliability parameters (i.e., instantaneous BA demand) in real time.
1.5. Interchange 1.5.1 Instantaneous actual interchange with each Balancing Authority 1.5.2 Current Interchange Schedules with each Balancing Authority by individual Interchange Transaction, including Interchange identifiers, and reserve responsibilities 1.5.3 Interchange Schedules for the next 24 hours	Recommendations: 1. RTBPTF recommends that the interchange data specified in item 1.5 (with the exception of interchange schedules for the next 24 hours) of the "Electric System Reliability Data" appendix shall be provided at least every 10 seconds. 2. The interchange schedules for the next 24 hours shall be provided with every schedule update. Rationale: 1. RTBPTF believes that update frequency of at least every 10 minutes is not sufficient for responsible entities to have the most current operating data to monitor critical reliability parameters (i.e., instantaneous actual interchange with each BA and Current Interchange Schedules with each BA by individual Interchange Transaction, including Interchange identifiers, and reserve responsibilities) in real time. 2. RTBPTF believes that it is sufficient to provide interchange schedules for the next 24 hours when new updates are available, i.e., when schedules are changed.
1.6. Area Control Error and frequency 1.6.1 Instantaneous area control error 1.6.2 Clock hour area control error 1.6.3 System frequency at one or more locations in the Balancing Authority	Recommendations: 1. RTBPTF recommends that the area control error (ACE) and frequency data specified in item 1.6 (with the exception of clock-hour ACE) of the "Electric System Reliability Data" appendix shall be provided at least every 10 seconds. 2. RTBPTF recommends that the clock-hour ACE shall be provided with every hourly update. Rationale: 1. RTBPTF believes that update frequency of at least every 10 minutes is not sufficient for responsible entities to have the most current operating data to monitor critical reliability parameters (ACE and frequency data) in real time. 2. The clock-hour area control error does not need to be updated every 10 seconds; an hourly update of the data is sufficient.

Type of Reliability Data	Discussion
2. Other operating information updated as soon as available 2.1. Interconnection Reliability Operating Limits and System Operating Limits in effect 2.2. Forecast of operating reserve at peak, and time of peak for current day and next day 2.3. Forecast peak demand for current day and next day 2.4. Forecast changes in equipment status 2.5. New facilities in place. 2.6. New or degraded special protection systems 2.7. Emergency operating procedures in effect 2.8. Severe weather, fire, or earthquake 2.9. Multi-site sabotage	Recommendation: 1. RTBPTF recommends that an additional item (i.e., Status of Special Protection Systems) be added to item 2 in this list. Rationale: 1. Standard IRO-005 (Requirement R1) states "[e]ach Reliability Coordinator shall monitor its Reliability Coordinator Area parameters, including but not limited to the following…R1.1. Current status of Bulk Electric System elements (transmission or generation including critical auxiliaries such as Automatic Voltage Regulators and Special Protection Systems) and system loading." For completeness, the status of Special Protection Schemes should be included in this list.

Table 1.1-28 — Electric System Reliability Data (TOP-005, Requirement R1, Attachment 1) and RTBPTF Recommendations

3. NERC Reliability Standard IRO-002, Reliability Coordination – Facilities

RCs need information, tools, and other capabilities to perform their responsibilities. Requirement R5 of IRO-002 states "[e]ach Reliability Coordinator shall have detailed real-time monitoring capability of its Reliability Coordinator Area and sufficient monitoring capability of its surrounding Reliability Coordinator Areas to ensure that potential or actual System Operating Limit or Interconnection Reliability Operating Limit violations are identified. Each Reliability Coordinator shall have monitoring systems that provide information that can be easily understood and interpreted by the Reliability Coordinator's operating personnel, giving particular emphasis to alarm management and awareness systems, automated data transfers, and synchronized information systems, over a redundant and highly reliable infrastructure."

Requirement R6 states "[e]ach Reliability Coordinator shall monitor Bulk Electric System elements (generators, transmission lines, buses, transformers, breakers, etc.) that could result in SOL or IROL violations within its Reliability Coordinator Area. Each Reliability Coordinator shall monitor both real and reactive power system flows, and operating reserves, and the status of Bulk Electric System elements that are or could be critical to SOLs and IROLs and system restoration requirements within its Reliability Coordinator Area."

In context, the standards quoted above do not specify which bulk electric system elements need to be telemetered. Entities cannot be expected to use "information, tools, and other capabilities" without a clear understanding of the components of the system that need to be monitored or require telemetry data.

Recommendation – S2

Compile and maintain a list of all bulk electric system elements within RC's area of responsibility.

RTBPTF Recommendations

Once the bulk electric system definition is clarified, per the recommendation above, RTBPTF recommends that a new requirement be established under the current Standard IRO-002 (Reliability Coordination — Facilities) that shall apply to RCs and specify which bulk electric system elements need to be telemetered. The following requirement is recommended.[7]

PR1. Each reliability coordinator shall develop and maintain a list (the "Bulk Electric System Elements List") of specific bulk electric system elements (generators, transmission lines, buses, transformers, breakers, etc.) within its reliability coordinator area. The regional reliability organizations shall oversee this process within their regions. For consistency, this list shall be based upon the "Electric System Reliability Data" specified in Standard TOP-005. The Bulk Electric System Elements List shall contain the bulk electric system elements (within the reliability coordinator's area) necessary to allow identification of potential or actual SOL/IROL violations.

PR1.1. Each reliability coordinator shall specify the monitoring methodology for each item on its Bulk Electric System Elements List (i.e., whether monitoring by direct or indirect methods).

PR1.2. For bulk electric system elements to be monitored directly, each reliability coordinator shall also specify the characteristics for specific data types (i.e., MW, kV, breaker status, etc.) that shall be telemetered for specific facilities (i.e., transmission lines, transformers, generators, etc.) at specific voltage levels (i.e., 765 kV, 500 kV, etc.). The telemetry data characteristics shall include, but not be limited to, the following characteristics: update frequency (whether periodic or by exception), latency characteristics, and quality codes.

PR1.3. Each reliability coordinator shall telemeter items listed in the Bulk Electric System Elements List (generators, transmission lines, buses, transformers, breakers, etc.) for which a direct monitoring methodology is specified and shall provide information that can be easily

[7] Proposed requirements are designated "PR," and proposed measures are designated "PM."

understood and interpreted by the reliability coordinator's operations personnel. Update frequency shall conform to the "Electric System Reliability Data" list as specified[8] in Standard TOP-005 for each data type.

RTBPTF recommends the following measure for the requirement stated above:

PM1. The reliability coordinator shall maintain the "Bulk Electric System Elements List" document as stated in Requirement PR1.

Rationale

RTBPTF believes that a requirement specifying a methodology for documenting the bulk electric system elements for which telemetering is required within an RC area removes any vagueness regarding what data must be provided (and by what methodology and update frequency) by reliability entities within the RC area. The recommendation above formalizes a process for RCs to document which bulk electric system elements they need to monitor and telemeter within their RC area.

4. *NERC Reliability Standard IRO-005, Reliability Coordination — Current-Day Operations*

Standard IRO-005 states that "[t]he Reliability Coordinator must be continuously aware of conditions within its Reliability Coordinator Area and include this information in its reliability assessments. The Reliability Coordinator must monitor Bulk Electric System parameters that may have significant impacts upon the Reliability Coordinator Area and neighboring Reliability Coordinator Areas."

Requirement R1 states "each reliability coordinator shall monitor its reliability coordinator area parameters, including but not limited to:[9]

- R1.1. Current status of bulk electric system elements (transmission or generation including critical auxiliaries such as automatic voltage regulators and special protection systems) and system loading;
- R1.2. Current pre-contingency element conditions (voltage, thermal, or stability), including any applicable mitigation plans to alleviate SOL or IROL violations, and including the plan's viability and scope;
- R1.3. Current post-contingency element conditions (voltage, thermal, or stability), including any applicable mitigation plans to alleviate SOL or IROL violations, and including the plan's viability and scope;
- R1.4. System real and reactive reserves (actual versus required);
- R1.5. Capacity and energy adequacy conditions;
- R1.6. Current ACE for all of its balancing authorities;

[8] Take note that the RTBPTF recommends changes to the "Electric System Reliability Data".
[9] The numbering scheme for these requirements were adapted to the current numbering scheme in the current version of Standard IRO-005.

R1.7. Current local or transmission loading relief procedures in effect;
R1.8. Planned generation dispatches;
R1.9. Planned transmission or generation outages; and
R1.10. Contingency events

For each of the requirements stated above for Standard IRO-005 (Requirement R1), no measures are currently specified. Requirement R1 mandates that each RC monitor its RC area parameters. Although the requirement is specific as to the parameters that need to be monitored, it does not specify any compliance measures.

Recommendation – S3

Add new requirements and measures pertaining to RC monitoring of the bulk electric system.

RTBPTF Recommendations

In general, the survey results support the availability of telemetry data for the RC area parameters mentioned in Standard IRO-005 (Requirement R1). As discussed previously, it is difficult to recommend measures for Standard IRO-005 (Requirement R1) without resolving the definition of the term "bulk electric system." Once the bulk electric system definition is clarified, RTBPTF recommends the following measures[10] for Standard IRO-005 (Requirements R1)[11].

PM1. The following are measures for each of the requirements R1.1-R1.6, and R1.10:

PM1.1. The reliability coordinator's Bulk Electric System List (as required in Standard IRO-002)[12] shall contain the status of bulk electric system elements (transmission or generation including critical auxiliaries such as automatic voltage regulators and special protection systems) and system loading necessary for the reliability coordinator to monitor its reliability coordinator area parameters. The reliability coordinator shall demonstrate, on request, that the reliability coordinator is monitoring every item listed in the Bulk Electric System Elements List.
In addition to the reliability coordinator's Bulk Electric System List, the reliability coordinator shall also

[10] The numbering scheme for these proposed measures (PM) coincides with the existing requirements – i.e., the proposed measure for Requirement R1.1 is numbered PM1.1.
[11] RTBPTF omitted any recommendations for measures related to Standard IRO-005 (Requirements R1.7-R.9) because they are not within RTBPTF's scope; these reliability coordinator parameters do not involve telemetry data or other tools discussed in this report.
[12] See recommendations for Standard IRO-002 above.

demonstrate the monitoring of bulk electric system elements (transmission or generation including critical auxiliaries such as automatic voltage regulators and special protection systems) and system loading necessary for the reliability coordinator to monitor its reliability coordinator area parameters within its wide area.

PM1.2. The reliability coordinator shall demonstrate the monitoring of current pre-contingency element conditions (voltage, thermal, or stability), including any applicable mitigation plans to alleviate SOL or IROL violations, and including the plan's viability and scope by having a display showing the contingency analysis base-case solution available to the reliability coordinator. The display shall show current pre-contingency element conditions within the reliability coordinator's wide area.

PM1.3. The reliability coordinator shall demonstrate the monitoring of current post-contingency element conditions (voltage, thermal, or stability), including any applicable mitigation plans to alleviate SOL or IROL violations, and including the plan's viability and scope by having a display showing the contingency analysis solution for each defined contingency available to the reliability coordinator. The display shall show current post-contingency element conditions within the reliability coordinator's wide area.

PM1.4. The reliability coordinator shall demonstrate the monitoring of system real and reactive reserves (actual versus required) by having displays (or visualization tools) showing the real-time information related to system real and reactive reserves[13] (actual versus required) available to the reliability coordinator. The displays (or visualization tools) shall show information on system real and reactive reserves (actual versus required) within the reliability coordinator's wide area.

PM1.5. The reliability coordinator shall demonstrate the monitoring of capacity and energy adequacy conditions by having displays (or visualization tools) showing the real-time information related to capacity and energy adequacy conditions available to the reliability coordinator. The displays (or visualization tools) shall show information on capacity and energy adequacy conditions within the reliability coordinator's wide area.

[13] Note that one of the major issues that RTBPTF identifies in this report (see the Introduction) as needing resolution from NERC and the industry is the specification of what constitutes acceptable reactive reserves.

PM1.6. The reliability coordinator shall demonstrate the monitoring of the current ACE for all of its balancing authorities by having displays (or visualization tools) showing the real-time ACE for all of its balancing authorities available to the reliability coordinator.

PM1.7. The reliability coordinator shall demonstrate the monitoring contingency events by having displays (or visualization tools) showing time-stamped contingency events available to the reliability coordinator. The displays (or visualization tools) shall show contingency events data/information within the reliability coordinator's wide area.

Rationale

For the proposed measure PM1.1, RTBPTF interprets the "current status of Bulk Electric System elements (transmission or generation including critical auxiliaries such as Automatic Voltage Regulators and Special Protection Systems) and system loading" as stated in Standard IRO-005 (Requirement R1.1) as referring to some of the items contained in the Bulk Electric System Elements List; RTBPTF recommends the Bulk Electric System Elements List above as a new requirement in Standard IRO-002. Relating the measure for Standard IRO-005 (Requirement R1.1) to the Bulk Electric System Elements List provides a direct way to document what is being monitored by reliability coordinators.

For the proposed measures PM1.2 and PM1.3, RTBPTF believes that having the contingency analysis base-case solution and contingency analysis solution for each defined contingency available to the RC sufficiently demonstrates the monitoring of "current pre- and post-contingency element conditions." Telemetry data indirectly support the contingency analysis application output/solution. Section 2.6 of this report, Contingency Analysis, discusses recommendations for contingency analysis.

For proposed measure PM1.4, RTBPTF interprets "system real and reactive reserves (actual versus required)" as the output of the reactive reserve monitor (a type of visualization tool). This application monitors reactive reserves (static and dynamic) in local geographic areas or major load centers and can send an alarm to the operator when a unit in the area reaches its reactive capability or the minimum reactive reserve requirement for the area is approached. Telemetry data indirectly support the reactive reserve monitor output/solution. Section 2.2 of this report, Visualization Techniques, discusses recommendations for visualization tools.

For proposed measure PM1.5, RTBPTF interprets "capacity and energy adequacy conditions" as the output of the capacity assessment application.[14] The capacity assessment application gives an overview of available generation capacity (MW or Mvar) in real time. Telemetry data indirectly support the capacity assessment application output/solution. Section 2.12 of this report, Capacity Assessment, discusses recommendations for the capacity assessment application.

For proposed measure PM1.6, RTBPTF believes that the current ACE for all of an RC's BAs could be obtained as ICCP-specific data from the BAs. Each RC could demonstrate compliance by showing the monitoring (through ICCP data exchange or direct telemetry methods) of the current ACE for all the RC's BAs. A summary display showing the ACE for all of an RC's BAs provides a measure for Standard IRO-005 (Requirement R1.6). Standard TOP-005 also requires current ACE data.

For proposed measure PM1.10, RTBPTF believes that a contingency event could result from the change in status of a single or a combination of multiple bulk electric system elements. For example, when a 230-kV transmission line contingency event occurs, it could be the result of all of the transmission circuit breakers related to the 230-kV transmission line having a change of status to "open." A summary display showing the contingency events provides a measure for Standard IRO-005 (Requirement R1.10). This summary display could also be the output of the alarm tool that selectively lists all of the contingency events for the RC wide area.

5. NERC Reliability Standard PRC-001, System Protection Coordination
The purpose of Standard PRC-001 is "to ensure system protection is coordinated among operating entities." Requirement R6 mandates that "[e]ach Transmission Operator and Balancing Authority shall monitor the status of each Special Protection System in their area, and shall notify affected Transmission Operators and Balancing Authorities of each change in status."

Standard PRC-001 (Requirement R6) is the same as Standard IRO-005 (Requirement 1.1) as related to special protection schemes. Standard PRC-001 applies to TOPs and BAs; Standard IRO-005 applies to RCs.

There are currently no specified measures for Standard PRC-001 (Requirement R6).

[14] An equivalent application could be substituted for a capacity assessment application as long as the data and displays (or visualization tools) show the "capacity and energy adequacy conditions."

RTBPTF Recommendation

In PRC-001 (Requirement R6), RTBPTF interprets “monitor” to mean that special protection system (SPS) status needs to be provided via telemetry or another real-time method. Telemetry is the most direct and current method for monitoring special monitoring systems. RTBPTF recommends that PRC-001 (Requirement R6) be modified to the following:

PR1. Each transmission operator and balancing authority shall monitor the status of each special protection system (SPS) in the transmission operator’s or balancing authority’s area via telemetry or another real-time method, and shall notify affected transmission operators and balancing authorities of each change in status. Each transmission operator and balancing authority shall also notify the host reliability coordinator via the use of telemetry data systems of each change in status.

RTBPTF recommends the following measure for the requirement stated above:

PM1. Each transmission operator and balancing authority shall demonstrate the monitoring the status of each special protection system (SPS) in the transmission operator’s or balancing authority’s area by having displays (or visualization tools) showing the real-time information related to the status of each special protection system (SPS) in the transmission operator’s or balancing authority’s area.

Rationale

RTBPTF interprets the monitoring of “the status of each Special Protection System” as the output of the remedial action scheme (RAS) tool (a subset of visualization tools discussed in Section 2.2, Visualization Techniques). The RAS allows users to: monitor the status of critical power system parameters, measure the proximity of these parameters to the triggering conditions for special protection schemes or total system failure, and alarm operators and advise them of actions required to mitigate pending problems. Telemetry data indirectly support the RAS application output/solution. Section 2.2, Visualization Techniques, of this report discusses the recommendations for visualization tools (including RAS). In addition, RTBPTF has recommended adding monitoring of the status of SPSs as part of the ‘Electric System Reliability Data’ appendix (see recommendations for Standard TOP-005).

6. NERC Reliability Standard TOP-006, Monitoring System Conditions

The purpose of Standard TOP-006 is “to ensure critical reliability parameters are monitored in real-time.” Standard TOP-006 specifies the critical system parameters to be monitored by responsible entities. The requirements for Standard TOP-006[15] are listed below:

- R1. Each Transmission Operator and Balancing Authority shall know the status of all generation and transmission resources available for use.
  - R1.1. Each Generator Operator shall inform its Host Balancing Authority and the Transmission Operator of all generation resources available for use.
  - R1.2. Each Transmission Operator and Balancing Authority shall inform the Reliability Coordinator and other affected Balancing Authorities and Transmission Operators of all generation and transmission resources available for use.
- R2. Each Reliability Coordinator, Transmission Operator, and Balancing Authority shall monitor applicable transmission line status, real and reactive power flows, voltage, load-tap-changer settings, and status of rotating and static reactive resources.
- R3. Each Reliability Coordinator, Transmission Operator, and Balancing Authority shall provide appropriate technical information concerning protective relays to their operating personnel.
- R4. Each Reliability Coordinator, Transmission Operator, and Balancing Authority shall have information, including weather forecasts and past load patterns, available to predict the system's near-term load pattern.
- R5. Each Reliability Coordinator, Transmission Operator, and Balancing Authority shall use monitoring equipment to bring to the attention of operating personnel important deviations in operating conditions and to indicate, if appropriate, the need for corrective action.
- R6. Each Balancing Authority and Transmission Operator shall use sufficient metering of suitable range, accuracy and sampling rate (if applicable) to ensure accurate and timely monitoring of operating conditions under both normal and emergency situations.
- R7. Each Reliability Coordinator, Transmission Operator, and Balancing Authority shall monitor system frequency.

The *FERC Staff Assessment* states: "[t]he standard does not have any Compliance Measures and Levels of Noncompliance and without such specificity, the ERO will not have norms that are specific enough to implement consistent and effective enforcement." On the topic of real-time monitoring in Standard TOP-006,[16] The *FERC Staff Assessment* states: "while the requirements identify the data to be gathered, they fail to describe the tools necessary to turn that data into critical reliability parameters, i.e., system capability or contingency analysis, which are required to achieve situational awareness. Reliability Coordinators, Transmission Operators, and Balancing

[15] These requirements are listed verbatim from Standard TOP-006.
[16] "To ensure critical reliability parameters are monitored in real-time."

Authorities must be aware of the status of their respective systems, and such situational awareness cannot be obtained by viewing massive amounts of raw data. The standard does not contain any Measures to assess compliance with Requirements or Levels of Non-Compliance required for enforcement."

RTBPTF Recommendation

RTBPTF interprets "critical reliability parameters" as outputs of some of the tools/applications described throughout this report and through the use of the displays (or visualization tools) for each respective tool/application. The tools/applications described throughout this report turn raw data (most of which are telemetry data) into "critical reliability parameters." RTBPTF recommends measures for the existing requirements within Standard TOP-006 that applicable entities demonstrate actual usage of such tools/applications pertinent to each requirement. RTBPTF recommends the following measures[17] for Standard TOP-006.

PM1. Each transmission operator and balancing authority shall demonstrate the knowledge of the status of all generation resources available for use by having displays (or visualization tools) showing the following:

- PM1.1. A summary display showing the host balancing authority information of all generation resources available for use, obtained from the balancing authority area generator operators. This summary display shall be the output of the host balancing authority's capacity assessment (or equivalent) application.
- PM1.2. The data from the summary display as stated in PM1.1 shall be shared with affected transmission operators and the reliability coordinator.

PM2. Each reliability coordinator, transmission operator, and balancing authority shall demonstrate the capability of monitoring of applicable transmission line status, real and reactive power flows, voltage, load-tap-changer settings, and status of rotating and static reactive resources by having displays (or visualization tools) showing the output of the reliability entity's telemetry data systems.

PM3. Each reliability coordinator, transmission operator, and balancing authority shall demonstrate the capability of providing appropriate technical information concerning protective relays to their operating personnel by having these documents (through paper copies or electronic documentation) readily available for their operating personnel.

PM4. Each reliability coordinator, transmission operator, and balancing authority shall demonstrate having the capability of obtaining

[17] The numbering scheme for these proposed measures (PM) coincides with the existing requirements (i.e., the proposed measure for Requirement R1 in numbered PM1).

information, including weather forecasts and past load patterns, available to predict the system's near-term load pattern by having displays (or visualization tools) showing the output of the reliability entity's historical/real-time/forecast weather systems as well the output of the reliability entity's near-term load forecast systems.

PM5. Each reliability coordinator, transmission operator, and balancing authority shall demonstrate the use of monitoring equipment (such as telemetry data systems and/or alarm tools) to bring to the attention of operating personnel important deviations in operating conditions and to indicate, if appropriate, the need for corrective action.

PM6. Each balancing authority and transmission operator shall demonstrate the use of sufficient metering with suitable range, accuracy and sampling rate (if applicable) to ensure accurate and timely monitoring of operating conditions under both normal and emergency situations by requiring the reliability entity to demonstrate the usage of telemetry data systems and/or alarm tools sufficient to support the update frequency specified by Standard TOP-005, "Electric System Reliability Data" appendix.

PM7. Each reliability coordinator, transmission operator, and balancing authority shall demonstrate the capability monitoring of system frequency by having displays (or visualization tools) showing real-time and current system frequency information.

Rationale

In general, the discussions below work in conjunction with RTBPTF's above recommendations for Standard IRO-002 and recommendations for modifications to the update frequency as mandated by Standard TOP-005. For each "critical reliability parameter," a specific tool(s)/application(s) is(are) suggested as a method to measure the usage of monitoring "critical reliability parameters."

For proposed measure PM1, RTBPTF believes that Requirement R1 works in conjunction with RTBPTF's recommendations for Standard IRO-002 and recommendations for modifications to the update frequency as mandated by Standard TOP-005 for "generation and transmission resources available for use." RTBPTF interprets this requirement as the active monitoring of bulk electric system elements (i.e., status of all generation and transmission resources available for use) within the entity's area of responsibility. In addition to monitoring of the status of all generation and transmission resources available for use, the critical reliability parameters specified in Requirement R1 could be derived using a capacity assessment (or equivalent) application. The capacity assessment (or equivalent) application gives an overview of available generation capacity (MW or Mvar) in real time. Telemetry data indirectly support the capacity assessment application output/solution. Section 2.12 of this report, Capacity Assessment, discusses the recommendations for the capacity assessment application.

For proposed measure PM2, RTBPTF believes that Requirement R2 works in conjunction with RTBPTF's recommendations above for modifications to update frequency as mandated by Standard TOP-005. RTBPTF interprets this requirement as the active monitoring of bulk electric system elements (i.e., applicable transmission-line status, real and reactive power flows, voltage, load-tap-changer settings, and status of rotating and static reactive resources) within the entity's area of responsibility by using the entity's telemetry data systems.

For proposed measure PM3, RTBPTF supports the notion of operators having access to documentation of appropriate technical information concerning protective relays.

For proposed measure PM4, RTBPTF believes that operators need historical/real-time/forecast weather information. These types of information are readily available from the Internet. The measure for this requirement mandates that weather information that may affect the real-time and forecasted load needs to be accessible to operators and used by the entity's near-term load forecast systems.

For proposed measure PM5, RTBPTF reiterates the need for demonstrated usage of monitoring equipment (such as telemetry data systems and/or alarm tools) to bring to the attention of operating personnel important deviations in operating conditions and to indicate, if appropriate, the need for corrective action.

For proposed measure PM6, RTBPTF interprets "timely monitoring" as following the update frequency mandated by Standard TOP-005, "Electric System Reliability Data" appendix. An entity may choose to exceed the minimum requirement mandated by the appendix to ensure timely dissemination of critical information for operating personnel.

For proposed measure PM7, RTBPTF believes that reliability entities should demonstrate compliance by having displays (or visualization tools) that show real-time frequency from all telemetry sources.

7. NERC Reliability Standard VAR-001, Voltage and Reactive Control

The purpose of Standard VAR-001 is "to ensure voltage levels, reactive flows, and reactive resources are monitored, controlled, and maintained within limits in ***real time*** [emphasis added] to protect equipment and the reliable operation of the Interconnection." Requirement R1 mandates that "each Transmission Operator, individually and jointly with other Transmission Operators, shall ensure that formal policies and procedures are developed, maintained, and implemented for monitoring and controlling voltage levels and Mvar flows within their individual areas and with the areas of neighboring Transmission Operators." Standard VAR-001 (Requirement R1) does not specify any measures for compliance.

RTBPTF Recommendation

RTBPTF recommends that a measure be established for Standard VAR-001 (Requirement R1) that requires the documentation of formal policies and procedures to ensure voltage levels, reactive flows, and reactive resources are monitored, controlled, and maintained within limits in real time to protect equipment and the reliable operation of the interconnection. The following measure is recommended for Standard VAR-001 (Requirement R1):

PM1. Each transmission operator shall document formal policies and procedures to ensure voltage levels, reactive flows, and reactive resources are monitored, controlled, and maintained within limits in real time to protect equipment and the reliable operation of the interconnection. These formal policies and procedures shall include the list of bulk electric system elements that need to be monitored via telemetry, such as voltage telemetry levels (from generators, transmission substations, etc.), reactive flows (from generators, transmission substations, transmission lines, etc.), and reactive power resources (static and dynamic). This document shall be made readily available to operators and updated as necessary.

Rationale

The Real-Time Tools Survey results described in the Summary of Findings section above show that ***not*** all voltage levels, reactive flows, and reactive resources are available as telemetry data. Standard VAR-001 mandates "real-time" monitoring of these data. As stated previously, RTBPTF believes that "monitoring" does not imply viewing large amounts of raw telemetered data but rather viewing data in a manner and format that allows operators to rapidly judge the state of the bulk electric system and take corrective action if necessary. Transmission operators could use a state estimator (with defined measurement-observability requirements) to monitor voltage levels, reactive flows, and reactive resources in real time. To protect equipment and maintain reliable operation of the interconnection, the pre- and post-contingency analysis solution could also be used to monitor voltage levels, reactive flows, and reactive resources in real time and assess impacts of contingencies on the reliability of the interconnection.

8. NERC Reliability Standard COM-001, Telecommunications

Each RC, TOP, and BA needs adequate and reliable telecommunications facilities internally and to others for the exchange of the interconnection and operating information necessary to maintain reliability. Requirement R2 states "each Reliability Coordinator, Transmission Operator, and Balancing Authority shall manage, alarm, test, and/or actively monitor vital telecommunications facilities. Special attention shall be given to emergency telecommunications facilities and equipment not used for routine communications."

RTBPTF Recommendation

Knowledge of the status of vital telecommunications facilities and equipment via telemetry internally and to/from related entities is essential for situational awareness. The telemetry data required to fulfill this requirement are closely tied to the issues addressed in Section 5.3, Facilities Monitoring, of this report. Section 1.2, ICCP-Specific Data, of this report addresses the methodology and management issues related to ICCP-specific data exchange. RTBPTF recommends rewording Requirement R2 as follows:

> R2. Each reliability coordinator, transmission operator, and balancing authority shall manage, alarm, test, and/or actively monitor vital telecommunications facilities. Special attention shall be given to emergency telecommunications facilities and equipment not used for routine communications. At a minimum, reliability coordinators, transmission operators, and balancing authorities shall provide telemetry data by vital telecommunications equipment (1) internally, (2) between the reliability coordinator and its transmission operators and balancing authorities, and (3) with other reliability coordinators, transmission operators, and balancing authorities.

Rationale

RTBPTF believes that the new language recommended for Requirement R2 specifies the types of telemetry data systems (telecommunications facilities) that are required (i.e., to support internal communications within the entity's area of responsibility, communications between the reliability coordinator and its transmission operators and balancing authorities, and communications with other reliability coordinators, transmission operators, and balancing authorities.)

Recommendations for New Operating Guidelines

RTBPTF does not recommend development of new operating guidelines for telemetry data at this time. The recommendations listed within this section indicate the need to clarify measurement methods specified in existing standards and compliance procedures. These clarifications are necessary before establishing new operating guidelines for telemetry data.

Areas Requiring More Analysis

RTBPTF is not recommending additional areas for analysis related to Telemetry Data.

Examples of Excellence

RTBPTF cites the Northeast Power Coordinating Council's "Criteria for Classification of Bulk Power System Elements (A-10)[18]" document as an example of excellence in establishing and facilitating a process/methodology for classifying bulk power system elements (See EOE-1 in Appendix E).

[18] http://www.npcc.org/documents/regStandards/Criteria.aspx

Section 1.2
ICCP-Specific Data

Definition

The Inter-Control Center Communications Protocol (ICCP) is a standard data-exchange format that is widely used in the electric utility industry to communicate information among operating entities.

Background

ICCP data are exchanged among reliability coordinators in the NERC ISN. In addition, several intra-regional and intra-company networks use ICCP to provide data to reliability coordinators from operating entities within each reliability coordinator's footprint.

Questions[19] in the ICCP-specific data section of the NERC Real-Time Tools Survey address ICCP data-exchange management and methodology. The survey questions examine issues and practices that affect the adequacy, quality, and timeliness of data ultimately provided to real-time tools for analyzing the reliability of the bulk electric system.

Summary of Findings

The majority of respondents to the NERC Real-Time Tools survey rate ICCP-specific data as essential to conducting reliability assessments and maintaining situational awareness. In addition, ICCP data are also rated as essential to generating accurate state estimator solutions. However, analysis of survey responses identifies the following problems and issues related to ICCP data:

- a lack of availability of the systems that supply ICCP data, including, notably, data-link failures
- a lack of data coordination and quality
- an absence of documented processes and procedures for managing ICCP systems
- a lack of timely responses to requests for ICCP data updates
- an extended or unknown period of data latency
- restricted access to some data

Based on analysis of the Real-Time Tools Survey results, RTBPTF recommends the following new reliability standards:

- All TOPs must have ICCP or equivalent systems subject to the same standard as RCs.
- Data-exchange coordination requirements must be imposed.

---

[19] RTBPTF relied extensively on the EPRI *Inter-Control Center Communications Protocol (ICCP) User's Guide* as a reference (EPRI TR-107176) to prepare survey questions.

- A requirement and measure of data-exchange-system reliability must be established.
- A minimum trouble-response time must be specified.
- Documented procedures must be established for activities such as data maintenance and update, data naming, and alarm response.
- ICCP systems must have redundant components to avoid data exchange interruptions.

The analysis of survey responses also reveals that systems equivalent to the NERC ISN are in use. Therefore, the task force recommendations should apply to both ISN and equivalent systems. The recommendations that follow the survey findings subsection below are written to apply to any type of data exchange system equivalent to the NERC ISN.

The task force does not recommend the creation of operating guidelines for ICCP data at this time.

The areas identified for more analysis include data latency, time skew, and time stamping and mapping of data to real-time tools.

The NERC Operating Reliability Subcommittee (ORS) specifically requested that RTBPTF investigate current practices of entities that exchange data via ICCP because of concerns about ICCP data quality and availability as well as ICCP's prevalence within the industry for exchanging operating reliability data.
The NERC Real-Time Tools Survey explores the various systems that survey respondents use to receive ICCP data. Approximately 50 percent (27 out of 55) of respondents report that they receive data through a direct connection to the ISN. In addition, more than 78 percent (43 out of 55) report that they also receive ICCP data via direct connections to other entities' systems, and approximately 45 percent (25 out of 55) receive ICCP data via data links internal to their companies. These results clearly show that equivalent systems are widely used in addition to the ISN. This finding has important bearing on the applicability of reliability standards governing data exchange. This issue is discussed further below in the subsection "Recommendations for New Reliability Standards."

The overwhelming majority, 75 percent (41 out of 55), of all respondents to the ICCP data section of the survey rate their ICCP data as "essential" for the value it adds to their situational awareness. All reliability coordinators rate ICCP data as "essential." The survey respondents make the following comments regarding the criticality of ICCP data:

> "Essential for state estimation and visual monitoring of non-owned areas."
>
> "ICCP data [are] essential for real-time security assessment."

> “In carrying out the RC role, ICCP information is required from BAs within [the] RC footprint.”
>
> “Our operators have tools that require ICCP data to work properly.”
>
> “The ICCP data [are] applied to the state estimator model to make the model observable in real-time.”
>
> “It [ICCP data] fills in holes in our data, provides backup on ties with neighbors, and provides a ‘wider’ view of the system.”

Although ICCP data are considered essential by the majority of survey respondents, the survey results reveal that these data are not consistently available in many cases. Approximately 58 percent (29 out of 50) of respondents have self-imposed availability requirements of 99 percent or higher for their ICCP systems. However, only 7 of the 13 RCs that have availability requirements report that they actually meet their own requirements.

ICCP data are used by most respondents (especially RCs) to perform state estimation. However, the survey responses indicate that ICCP system data-link failures rank highest on the list of ICCP-related problems affecting the ability of state estimators to generate a solution (see Table 1.2-1). One respondent made the following comment regarding the frustration resulting from losing a data link:

“Our biggest issue is with failure of entire ICCP data links from the data providing entity. We have issues with losing ICCP data from an entire utility on a periodic basis.”

The problem of ICCP data link failures is largely a result of lack of redundancy. Nearly one-third of all respondents (17 out of 53) report that they do not have redundant data links. Note that respondents report a higher level of redundancy for other aspects of their ICCP systems than for their data links. For example, nearly 90 percent (47 out of 53) of respondents have redundant ICCP servers, and nearly 78 percent (41 out of 53) have redundant network connections.

Other commonly reported ICCP-specific data problems that affect state estimator solutions include lack of maintenance coordination with other entities, poor data quality, and failover problems (see Table 1.2-1). One reason for frequent data coordination and quality problems is that fewer than half of the respondents (23 out of 49) have formal agreements with other entities that specify how data-set changes are to be communicated, coordinated, and tested. RTBPTF concludes that data-coordination requirements are necessary to alleviate many of the problems that affect state estimator solutions. These requirements will help ensure operators’ ability to assess transmission system reliability and maintain situational awareness.

ICCP Problems Impacting State Estimator Solutions	RC1	RC2	RC3	RC4	RC5	RC6	RC7	RC8	RC9	RC10	RC11	RC12	RC13	RC14	RC15	RC16	RC17	Other	Total
Data Link failure on your end	X	X	X	X				X	X	X				X	X			19	**28**
Data Link failure on the other end	X	X	X	X	X	X	X	X	X	X		X	X	X	X	X		20	**35**
Invalid, failed, or corrupted data received	X	X	X	X	X	X	X	X	X		X	X						13	**24**
Failover Problems	X	X	X			X	X	X					X					7	**14**
Uncoordinated maintenance activities (in house)	X	X		X	X		X											5	**10**
Uncoordinated maintenance activities (external)	X	X	X			X	X			X	X							10	**17**
Data time skew (i.e., mixing stale ICCP data with fresh SCADA data)	X	X	X	X		X												2	**7**
Software bugs	X	X						X						X				5	**9**
Interoperability issues (i.e., version incompatibility, user object incompatibility)		X		X	X													5	**8**
Extended bad quality indication	X				X				X									3	**6**

Table 1.2-1 — ICCP Problems Impacting State Estimator Solutions[20]

Most respondents report that they have very few documented processes or procedures for managing their ICCP systems (see Table 1.2-2). Although approximately 65 percent (32 out of 49) of all respondents have documented data-naming conventions, less than half have data-maintenance procedures (23 out of 49) or documented EMS data-mapping standards (19 out of 49), and only about 25 percent have documented test procedures (14 out of 49) or documented procedures for monitoring and measuring data-link performance (12 out of 49) and data availability (13 out of 49). In addition, only 60 percent (16 out of 27) of all respondents that exchange ICCP data via the NERC ISN indicate that they have the NERC *Data Exchange Working Group (DEWG) ISN Node Responsibilities and Procedures Document* even though this document is posted on the NERC web site. Even RCs, who are generally considered to maintain more documentation than TOPs and BAs (see Table 1.2-2), report very little.

The survey was not designed to allow respondents to identify by name other entities that do not perform well in providing consistently accurate, timely, and up-to-date data sets via ICCP data exchange. Therefore, it is not possible to use the survey responses to determine a correlation between the type and quality of an entity's documentation of internal processes and procedures and that entity's performance of ICCP data exchange as judged by those with whom the entity

[20] RC responses are indicated with "X." Aliases are used as column headers to mask the RCs' names. The aliases in this table are not necessarily consistent with those used in similar tables in this report. That is, "RC 1" in any given table may not be the same as "RC 1" or the equivalent identifier in another table in this report.

exchanges data. Several entities (particularly RCs) that report that they exchange large quantities of data via ICCP and that are known by RTBPTF members to perform those functions reasonably well report having several different types of documented processes and procedures. Therefore, the task force concludes that the lack of a consistent set of documentation is a significant impediment to an entity's ability to maintain its ICCP data exchange.

Table 1.2-2 — Documented ICCP Processes and Procedures[21]

Another data-coordination and management problem identified in the survey is timeliness of responses to requests for data set updates. Respondents report a wide range of turn-around times for these requests. Very few respondents (4 out of 50) report receiving same-day service for data-set updates, and only 30 percent (15 out of 50) report that they usually receive a response within a week. Still others have to wait up to two weeks (6 out of 50) or even as long as a month (5 out of 50) for a data-set update. In addition, several respondents (18 out of 50) report that response times for data set update requests depend upon the particular data provider.

The survey asked several questions related to data latency and its effects, but the responses are inconclusive. When asked how long it takes from the time a data point changes in the field until that change is represented in their local EMS

[21] Reliability coordinator responses are indicated with "X." Aliases are used as column headers to mask the RCs' names. The aliases in this table are not necessarily consistent with those used in similar tables in this report. That is "RC 1" in any given table may not be the same as "RC 1" or the equivalent identifier in another table in this report.

database (i.e. data latency), respondents report a broad range of data latency times ranging from a few seconds to a few minutes, and several do not know their data latency times (see Table 1.2-3). A few respondents identify time skew (defined here as the time difference between stale ICCP data and fresh SCADA data) as contributing to solution problems for their state estimators. Finally, the vast majority of respondents report that there are no time stamps on the ICCP data that they send (35 out of 51) or receive (27 out of 49). The task force concludes that more analysis and review of data latency and its impact on reliability assessment and situational awareness are needed before definitive minimum requirements can be established.

In Section 1.1, Telemetry Data, of this report, RTBPTF recommends decreasing the required update frequency for operational reliability data from 10 minutes to 10 seconds. If this recommendation is implemented, some data latency impacts should be reduced. However, unless “updates” are always made with fresh data (rather than simply forwarding old data to recipients every 10 seconds until fresh data are available from the source), there will be few improvements in data latency.

Analog Point Data Latency	***Responses***		**Status Point Data Latency**	***Responses***

Other	4		Other	3

Table 1.2-3 — ICCP Data Latency

NERC Reliability Standard TOP-005-0, Operational Reliability Information, requires RCs, TOPs, and BAs to provide data to one another for the purpose of performing operational reliability assessments and coordinating reliable operations unless otherwise agreed. Requests for these data are often rejected for a variety of reasons, as indicated in Tables 1.2-4 and 1.2-5. The survey results raise the question of whether this requirement is being consistently met. The task force concludes that the industry requires specification of what can be considered a legitimate restriction to data access.

Criteria Used by Respondents to Restrict Access to Data	RC1	RC2	RC3	RC4	RC5	RC6	RC7	RC8	RC9	RC10	RC11	RC12	RC13	RC14	RC15	RC16	RC17	Others	Total

Table 1.2-5 — Suppliers' Restrictions on Respondents' Access to Data

Survey respondents identify operator awareness of ICCP system health as an important issue. Approximately 80 percent (41 out of 51) state that their system operators monitor the status of their ICCP data links. Approximately 70 percent (35 out of 51) of respondents provide audible alarms to make operators aware of ICCP system problems, and 50 percent (26 out of 51) have ICCP system "health" visualization displays for their operators. Operators must be quickly made aware when state estimator solutions may be unreliable because of ICCP data problems.

The August 14, 2003 *Outage Task Force Final Blackout Report* finds that the reliability data that MISO was receiving via the ECAR data network and other data links were not linked (mapped) so that MISO's state estimator could be automatically informed of status change of a key transmission line.[22] The Real-

---

[22] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April. page 48.

Time Tools Survey explored this issue by asking respondents to quantify the ICCP status point data and ICCP analog data they receive that are mapped into respondents' real-time network application databases and used by these applications. The results are summarized in Tables 1.2-6 and 1.2-7. Most RCs, as expected, map a large percentage of the ICCP data they receive, as do many other respondents, but a few RCs and other respondents could improve in this area.

Mapping ICCP data to a real-time network model database often requires that the model be modified to provide sufficient detail to allow linking of specific data. For example, an external station represented as a bus-branch model will have to be expanded to include circuit breakers at the correct locations to permit mapping of specific breaker status points to the correct devices. This effort is resource intensive; resource constraints may have prevented some respondents from performing all of the mapping that they ultimately intend to accomplish. This could be one reason that some respondents report low mapping percentages (or do not reply to this question at all). The task force concludes that the specific data that should be mapped to real-time tools are dependent upon the NERC definitions of bulk electric system and wide-area view. As previously stated, the task force believes that these definitions are unclear. Therefore, the task force concludes that the issue of data mapping requires more analysis.

ICCP Status Point Data Mapped to Real-Time Tools	RC1	RC2	RC3	RC4	RC5	RC6	RC7	RC8	RC9	RC10	RC11	RC12	RC13	RC14	RC15	RC16	RC 17	Others	Total

Survey respondents were asked to quantify how long it takes to resolve problems internal to their systems and how long it takes responsible external entities to respond to and resolve problems in those entities' systems. Table 1.2-8 summarizes the responses. A large majority, 76 percent (38 out of 50) of respondents, can resolve internal problems within one hour. Only 44 percent (22 out of 50) can get external problems resolved within one hour; however, 74 percent (37 out of 50) can get resolution within two hours. The task force concludes that these time frames are achievable and necessary thresholds for a trouble-response standard because of the importance of these data for maintaining reliability.

Trouble Response Time Range	*Internal Problems*		*External Problems*
< 1 hour	38		22
1-2 hours	6		15
2-4 hours	3		1
4-8 hours	2		7
> 1 day	0		1
Other(s)	1		4

Table 1.2-8 — ICCP Trouble-Response Times

Survey respondents report various methods for creating ICCP object IDs. Approximately 58 percent (29 out of 51) of respondents create globally unique data names used by all parties. Twenty-seven percent report using the object names provided by the source. Only about 12 percent (6 out of 51) of respondents generate sequential numbers for ICCP object IDs, and an overwhelming majority, 76 percent (38 out of 51), have a structured naming convention such as a composite key (i.e., Station ID + Device ID + Point ID, etc.). Recent discussions in the ISN community have identified data recipients' difficulty in keeping abreast of data-point name changes instituted by data providers. It is widely recognized that the names of data points utilizing a composite key naming convention are likely to change when some component of the name changes, such as when a station is renamed or a device is replaced with a different type of device (replacing a switch with a breaker, for example). By contrast, data points named with sequentially generated numbers are unlikely to need changing. Nevertheless, the Real-Time Tools Survey indicates that composite key names are much more common than sequential numbers, probably because data providers who create the names find it easier for purposes of data point checkout and testing to list data point details within the name. Despite these issues, the task force concludes that a standard naming convention would be difficult to implement and therefore does not recommend one. Instead, RTBPTF recommends that this issue be addressed in comprehensive standards governing all aspects of data-exchange coordination.

Recommendations for New Reliability Standards

Based on analysis of the Real-Time Tools Survey results, RTBPTF recommends the following:

- All transmission operators must be required to have ICCP or equivalent systems subject to the same standard as reliability coordinators.
- Data-exchange coordination requirements must be imposed.
- A requirement and measure of data-exchange-system reliability must be established.
- A minimum trouble-response time must be specified.
- Documented procedures must be established for activities such as data maintenance and update, data naming, and alarm response.

- ICCP systems must have redundant components to avoid data-exchange interruptions.

Each of these recommendations is described in detail below.

NERC Standard TOP-005-0, Operational Reliability Information, currently specifies several general requirements (R1 – R5) and one measure (M1) to "ensure reliability entities have the operating data needed to monitor system conditions within their areas." The requirements do not specify use of the ICCP protocol; however, requirement R3 refers as follows to the NERC ISN, which utilizes ICCP for data exchange:

> Upon request, each reliability coordinator shall, via the ISN or equivalent system, exchange with other Reliability Coordinators operating data that are necessary to allow the Reliability Coordinators to perform operational reliability assessments and coordinate reliable operations.

The results of the Real-Time Tools Survey indicate that several other regional networks over which operational reliability data are exchanged also use the ICCP protocol. The task force concludes that these regional networks should be considered "equivalent systems." Some other data-exchange arrangements do not use the ICCP protocol but arguably could be considered "equivalent systems." Requirement R3 of TOP-005-0 applies only to RCs; however, survey respondents clearly indicate, as noted in the Survey Findings section above, that ICCP data are essential for reliability assessment and situational awareness, including the ability to produce a state estimator solution. The task force concludes that ICCP and "equivalent systems" are critical reliability tools for both RCs and TOPs. Therefore, the task force recommends as follows.

RTBPTF Recommendation

> All Transmission Operators shall have ICCP or equivalent systems for data exchange and shall be subject to the same standards for this tool as reliability coordinators. Other responsible entities who are using ICCP or equivalent systems to support or complement their reliability coordinator's ability to operate the bulk electric system reliably in accordance with formal agreements, contracts, or established practices or procedures, shall be subject to the same standards for ICCP or equivalent systems as their reliability coordinator's.

The task force believes that this statement of applicability is also consistent with Requirement R3 of Reliability Standard IRO-002, Reliability Coordination – Facilities, which states:

> Each reliability coordinator — or its Transmission Operators and Balancing Authorities — shall provide, or arrange provisions for, data

exchange to other reliability coordinators or Transmission Operators and Balancing Authorities via a secure network.

Each of the following recommendations is written to apply to any type of data exchange system used to support compliance with NERC Reliability Standard TOP-005-0.

Recommendation – S4

Develop data-exchange standards

Data Exchange Coordination Standards

Survey respondents identify a number of issues related to ICCP data exchange, as noted in the Survey Findings section above.

RTBPTF Recommendation

RTBPTF recommends that new requirements be added to standard TOP-005 that apply to all users and providers of data exchanged by ICCP or equivalent systems. These requirements will standardize the procedures, processes, and rules governing:

- Interoperability of ICCP and equivalent systems
- Data access restrictions
- Data-naming conventions
- Change management and coordination
- Joint testing and data checkout
- Quality codes
- Dispute resolution

This recommendation is also related to the issue of change management procedures for real-time models, as discussed in Sections 4.1, Model Characteristics, and 4.2 Modeling Practices and Tools, of this report. The task force recognizes the work already completed by NERC DEWG in these areas, which is documented in the *ISN Node Responsibilities and Procedures Document*.[23] The task force considers this work a good starting point for definitive and comprehensive requirements. The task force recommends that the *ISN Node Responsibilities and Procedures Document*, which currently does not have the force and effect of a standard, evolve into a standard developed in accordance with the recommendations of this report.

[23] http://www.nerc.com/~filez/isn.html

Availability requirements

The survey respondents identify problems associated with failure/lack of availability of systems providing ICCP data, particularly failures of data links, which directly impact state estimator solutions. The task force recommends that NERC Standard TOP-005-0 be revised to incorporate a requirement and a metric for data-exchange system availability. The fact that many entities have self-imposed availability requirements is evidence of the desirability of such a metric. The revised standard should specify how availability is to be calculated and measured.

RTBPTF Recommendation

The task force recommends that each data recipient track the availability of data from each provider of ICCP or equivalent system data. Each time a data set is received, the recipient would calculate the ratio of the number of data points received with “good” quality codes to the total number of data points expected. This ratio should exceed 99 percent for 99 percent of the sampled periods (i.e., 10 seconds each) over a calendar month. In addition, this ratio should not be less than 99 percent for 30 consecutive minutes.

Requiring data recipients to calculate data availability will reveal problems affecting data quality or availability anywhere in the data stream. RTBPTF also recommends that data providers be required to monitor availability of internal data systems used to provide data to others. Recommended standards for data system availability monitoring are included in the general recommendations in Section 5.4, Critical Applications Monitoring, of this report.

The following diagram (Figure 1.2-1) is an example of the distribution of responsibilities for data availability calculation and monitoring.

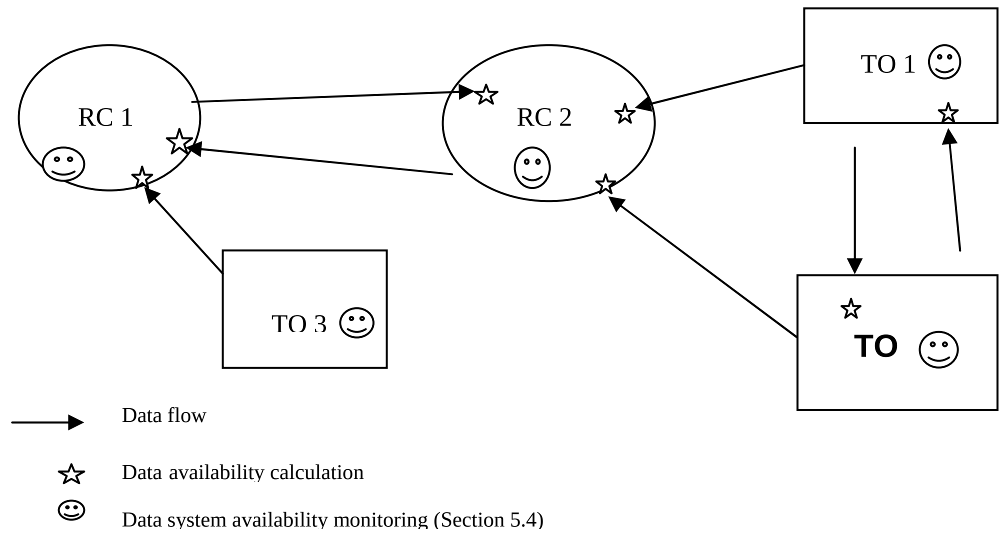

Figure 1.2-1 — Example of Data Distribution Responsibilities

Recommendation – S5

Develop data-availability standards and a process for trouble resolution and escalation

Trouble-response times

The internal and external trouble-response times reported by survey participants, as noted in the Survey Findings section above, are achievable thresholds for a trouble-response standard.

RTBPTF Recommendation

The task force recommends the establishment of minimum response times for the restoration of data exchange among control centers following the loss of a data link or other problems within the source system. These minimum requirements could be incorporated within the data-exchange coordination standards recommended above. Alternatively, minimum response times could be specifically defined as a new requirement and a new measure under NERC Standard TOP-005-0. In addition, the task force recommends the development of a trouble-resolution process that would be mandatory for all entities responsible for the management and maintenance of ICCP or equivalent systems that could be the cause of a loss of data-exchange capability with another system. These entities would be required to identify a mutually agreeable restoration target time with affected data recipients. The standard process would also include service restoration procedures and prioritization criteria.

Maintenance and management documentation

Most survey respondents possess very few documented procedures for managing their ICCP systems, as reported in the Survey Findings section above.
RTBPTF Recommendation
The task force recommends that all entities responsible for managing and maintaining ICCP or equivalent systems be required to have documented procedures for the support activities necessary to ensure compliance with the current and recommended requirements of NERC Standard TOP-005-0. At a minimum the following procedures and activities should be documented:

- Data maintenance and updates
- Testing
- System availability monitoring and measurement
- Troubleshooting
- EMS (real-time network applications) data-mapping standards
- Data-naming conventions
- Fault management (maintenance and display of error statistics)
- Alarm response

The task force recommends that NERC Standard TOP-005-0 be revised to incorporate a requirement and a measure for the above procedures. These procedures should be subject to self-certification and should be reviewed for completeness during the NERC compliance audits.

ICCP or equivalent system component redundancy

The Real-Time Tools Survey revealed a high degree of redundancy in respondents' ICCP systems. Note that redundant components support a high degree of system availability by ensuring that a single failure point will not make the system unavailable. The survey also revealed that some ICCP or equivalent systems did not have redundant data links. Many respondents identified the loss of a data link as a serious failure impacting the ability of their state estimators to produce accurate solutions.

RTBPTF Recommendation

Requirement R1.4 of NERC Reliability Standard COM-001-0, Telecommunications, requires that "where applicable" telecommunications facilities "shall be redundant and diversely routed." The task force recommends that this requirement be expanded to specifically state that it applies to ICCP and equivalent systems. The standard should also require that all system upgrades, expansions, and replacements include the elimination of single points of failure.

Recommendations for Operating Guidelines

RTBPTF does not recommend the development of new operating guidelines pertaining to ICCP or equivalent systems.

Areas Requiring More Analysis

RTBPTF concludes that time skew, time stamp, and data latency require additional analysis by NERC.

Recommendation – A1

Investigate the impact of time skew on state-estimator solution quality.

Time skew and time stamping

The impact of data time skew on state estimator solution quality has been the subject of various technical papers during the past several years. The survey responses related to time skew and data latency were too general to allow the task force to identify a specific requirement for maximum data latency or minimum time skew based upon actual (as opposed to theoretical) experience. More detailed investigation, testing, and analysis are necessary before any standards can be developed, including requirements for time stamping of ICCP data or equivalent system data.

The task force recommends that NERC DEWG be tasked with studying these issues with the goal of "informing" the standards-setting process and identifying cost-effective standards or operating guidelines that would minimize the impacts of stale data on real-time reliability analysis and situational awareness.

Additionally, the task force recommends that DEWG validate or confirm the task force's recommendation in Section 1.1, Telemetry Data, of this report to revise the timing requirements in Attachment 1 of NERC Standard TOP-005. DEWG should also consider the data update requirements (periodic or by exception) necessary to support the requirements in NERC Standard IRO-002. Special consideration should be given to the communication of event-driven system changes such as a transmission-line trip that RCs need to analyze in real time.

Recommendation – A2

Identify necessary fidelity and scope of real-time models and the extent of the requisite data-exchange sets.

Mapping of data to real-time tools

The specific data that an RC, TOP, or other entity responsible for reliability should request from neighboring or nearby entities and map into its real-time tools databases or models is a function of many variables. Among these variables are the size and location of the entity, the "footprint" for which the entity is responsible, and the view of the external area necessary to monitor and coordinate system operations reliably. These same variables affect the extent and fidelity of the real-time models that must be built and maintained in order to perform real-time functions such as state estimation and contingency (security) analysis. The necessary fidelity and scope of real-time models and the extent of the requisite data-exchange sets needed to map to the models are ultimately dependent upon the definitions of bulk electric system and wide-area view. Section 1.1, Telemetry Data, of this report discusses the need to clarify the definition of bulk electric system, and Section 2.1, Alarm Tools, discusses the definition of wide-area view. Furthermore, Sections 4.1, Model Characteristics, and 4.2, Modeling Practices and Tools, recommend additional analyses of modeling criteria, especially as those criteria apply to areas external to an entity's footprint. This analysis should also explore the criteria for determining what external measurements must be mapped into the portions of real-time models representing areas external to an entity's area of responsibility.

Examples of Excellence

RTBPTF cites an automated trouble-tracking system that includes processes and procedures for reporting, notification, tracking, resolution, and escalation of ICCP data problems used by Independent System Operator (ISO) New England and its transmission owners as an example of excellence (See EOE-2 in Appendix E).

RTBPTF cites an automated monitoring system that periodically compares data-set time stamps to detect and alarm any data sets that have stopped updating for any reason used by ISO New England and its transmission owners as an example of excellence (See EOE-3 in Appendix E).

Section 1.3
Miscellaneous Data

Definition

Miscellaneous data are used by real-time applications/tools that may not be supported by basic SCADA and/or ICCP systems. Miscellaneous data include information on weather such as that available from commercial data services as well as information from sources such as substation relays, recorders, and monitoring units.

Background

Chapter 7 of the *Outage Task Force Final Blackout Report* includes an examination of causal factors common to all major outages during the past 40 years.[24] One cause common to several events (although not the August 14 blackout) was severe weather conditions. Examples include lightning storms, extreme heat, and high winds. Even though the blackout that led to the creation of RTBPTF was not specifically weather related, the lack of situational awareness is a recurring theme in the blackout report. The task force believes that the issue of situational awareness from an operator's perspective would be inadequately addressed without an investigation of weather data and their application in control centers. The investigation of the other types of miscellaneous data documented in this section of the report is intended to uncover situational awareness issues that might be addressed by less common or less familiar data.

The Real-Time Tools Survey miscellaneous data section encompassed weather, fault locator, and high-speed sampled data.

Summary of Findings

Survey results reveal that almost all respondents rely to some extent on weather data and perceive these data as valuable for situational awareness; in contrast, respondents do not rely on fault locator data and high-speed sampled data (including phasor data) to monitor system conditions in real time and maintain reliability. Based on these findings, RTBPTF recommends modifying existing standards to require that weather data be provided to operators but does not recommend new standards for fault locator or high-speed sampled data. The task force notes, however, that phasor measurement data are part of other current industry initiatives, and that NERC's *Reliability Standards Development Plan: 2007-2009* includes the possibility of a new standard for PMUs.

---

[24] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April. pp. 107-110.

Meteorological Data

Almost all survey respondents rely on meteorological data to some extent. Nearly 90 percent (47 out of 53) of the respondents to this section of the survey reported using some type of meteorological data to support situational awareness. Approximately 38 percent (18 out of 47) of those who use this type of data consider it “essential” or required for situational awareness, and almost half (23 out of 47) consider it ”desirable” and an enhancement of their operational capabilities.

Survey comments indicate that many respondents use weather data to improve load forecasts and monitor potential impacts of severe weather on system reliability. Others use data such as temperature and wind speed to calculate thermal limits. Less common uses of meteorological data include forecasting expected wind-generation levels and determining when to expedite transmission-line maintenance outages. Table 1.3-1 summarizes the types of meteorological data currently being monitored and used in real-time tools.[25]

Monitored (M) / Used (U)	RC1	RC2	RC3	RC4	RC5	RC6	RC7	RC8	RC9	RC10	RC11	RC12	RC13	RC14	RC15	RC16	RC17	Others
Temperature	M/U	M	M/U	M/U	M/U	M	U	M	U	M/U	M	M						26/8
Wind Speed/Direction	M/U	M	M	M	M/U	M	M		U	M/U		M						21/4
Relative Humidity	M	M	M/U	M		M			U		M							16/3
Dew Point	M	M	M/U	M/U	M/U	M			U									6/2
Ice Thickness	M	M					U											4/0

Lightning Information	M					U	U	M										16/2
Precipitation	M	M		M				M										18/0

Table 1.3-1 — Meteorological Data Monitored (M) and Used (U) in Real-Time Tools

Survey respondents place high value on meteorological data for supporting real-time operational capabilities and situational awareness. The following comments by respondents highlight the perceived value of weather data:

> “Knowing weather conditions throughout the state is essential to system operations.”

---

[25] Aliases are used as column headers to mask RC-s’ names. The aliases in this table are not necessarily consistent with those used in similar tables in this report. That is, “RC 1” in any given table is not the same as “RC 1” or the equivalent identifier in another table in this report.

> “You cannot have an accurate load forecast without good weather data.”

> “Weather information is essential to understanding and preparing for activity on the system.”

> “Wind speed and lightning information is used in determining when to restore lines early, from maintenance outages.”

> “We use meteorological data to calculate thermal limits and to monitor thunderstorms and ice storms.”

The survey asked how meteorological data are presented to operators. Approximately 61 percent (28 out of 46) of respondents provide these data on dynamically updated, dedicated EMS displays, and about 24 percent (11 out of 46) have dynamically updated, multi-purpose dashboard displays to support situational awareness. Other less commonly used methods of data presentation include: periodic reports, cable television, weather services via the Internet, and corporate meteorological department intranet web pages.

Because of the perceived value and prevalent usage of meteorological data for situational awareness, RTBPTF recommends adding a new requirement to an existing standard to address the necessity of providing weather data to operators.

Fault Locator Data

Survey results generally reveal that, when a fault causes a facility outage, fault locator data facilitate restoration. Almost 60 percent (30 out of 51) of respondents use fault locator data, but only about 20 percent (4 out of 21) of those who do not use it plan to add it in the future. Only 6 respondents who use these data rate them “essential“ for situational awareness. All but one of the other users consider these data ”desirable” for situational awareness. The following comments by survey respondents indicate the perceived value of fault locator data:

> “Fault location data is required for effective restoration after an outage. Written procedures require fault location data before circuit tests are performed.”

> “Reduces repair time and facilitates quicker isolation and partial restoration.”

> “We use the distance data of the distance relay flagged in every line fault.”

The survey also asked how fault locator data are presented to operators. Of the users who responded to this question, approximately 58 percent (15 out of 26) provide these data on dynamically updated, dedicated EMS displays. None of the users employs dynamically updated, multi-purpose dashboard displays. The remainder of the users either have to dial up fault locator relays to obtain data or have support personnel obtain and pass along the information, i.e., in oral or written reports.

Fault locator data are narrowly used to facilitate restoration of an out-of-service facility. The data are not used to monitor system conditions in real time to maintain reliability or prevent or mitigate IROL or SOL violations. Therefore, RTBPTF does not recommend any new standards or requirements for fault locator information.

High-Speed Sampled Data

In general, survey results reveal that high-speed sampled data, such as sequence-of-events data and PMU data, are currently used primarily for post-event analysis rather than real-time operations. Approximately 40 percent (20 out of 51) of respondents use high-speed sampled data, and only about 39 percent (12 out of 31) of those who do not use this type of data plan to add it in the future. Only 2 of the respondents who use this type of data consider it ”essential” for situational awareness; 15 respondents consider these data ”desirable” for situational awareness. The following comments by survey respondents indicate the perceived value of high-speed sampled data:

> “Used as an assist in analysis of system problems.”
>
> “[Sequence of Events] data is not used by real-time operators, but by engineering staff for post-event analysis.”
>
> “Used for post event analysis.”
>
> “Enhances capabilities, but is not essential.”
>
> “[Respondent] is investigating ways of getting PMU data into real time.”

The survey also asked how high-speed sampled data are presented to operators. Of the users (18) who responded to this question, only 3 provide these data on dynamically updated, dedicated EMS displays or multi-purpose “dashboard” displays. Ten other users provide operators with written or on-line reports, and the others apparently provide the data only to engineering or other support staff.

High-speed sampled data are narrowly used for post-event analysis, not to monitor system conditions in real time to help maintain reliability or prevent or mitigate IROL or SOL violations. Therefore, RTBPTF does not recommend any new standards or requirements for these data. However, the task force notes that real-time application of PMU data is part of the scope of other industry initiatives such as the Eastern Interconnection Phasor Project,[26] and there is a placeholder in NERC's *Reliability Standards Development Plan: 2007-2009* for a new standard for PMUs. According to the NERC work plan, "Several industry studies were recently issued and these studies need to be analyzed to determine appropriate requirements for a NERC standard."[27]

Recommendations for New Reliability Standards

Currently, NERC Reliability Standards contain only two requirements related to weather data. Standard TOP-006-0, Monitoring System Conditions, has a requirement (R4) that "Each Reliability Coordinator, Transmission Operator, and Balancing Authority shall have information, including weather forecasts and past load patterns, available to predict the system's near-term load pattern." Also, Attachment 1 of Standard TOP-005-1, Operational Reliability Information, lists "severe weather" among the data that RCs, TOPs, and BAs are expected to provide to and share with one another. There are no measures for either of these requirements.

Recommendation – S6

Develop a new weather data requirement to situational awareness and real-time operational capabilities.

RTBPTF Recommendation

RTBPTF recommends[28] that a new requirement be added to Standard TOP-005-1 to address the importance of weather data for situational awareness and real-time operational capabilities.

PR1. Each Reliability Coordinator, Transmission Operator, and Balancing Authority shall have dynamically updated real-time and forecasted weather data that are important to the operational capability and situational awareness of that particular entity so that operators can readily determine the current and near-term weather conditions that might affect monitoring or operation of their systems.

RTBPTF recommends the following measure for the requirement stated above:

PM1. Each Reliability Coordinator, Transmission Operator, and Balancing Authority shall document each type of weather data provided to operators and shall demonstrate the visualization tools or other means used to present these data to operators.

---

[26] http://phasors.pnl.gov/

[27] *NERC Reliability Standards Development Plan: 2007-2009.* p. 210.

[28] Proposed requirements are designated "PR," and proposed measures are designated "PM."

Rationale

Real-Time Tools Survey results indicate that many respondents provide and use meteorological data for purposes other than forecasting load. Because meteorological data have become increasingly available in control centers and are commonly used to enhance situational awareness and support real-time operational capabilities, it is desirable and practical to “raise the bar” to ensure that all operators in all control centers have the weather information they need to do their jobs.

Weather varies considerably from region to region, and individual RCs, TOPs, and BAs tend to monitor the meteorological data that are most important to their specific needs. Therefore, the proposed requirement does not standardize the weather data to be collected but instead allows each entity to continue to determine which data are most important for its operators. Because a majority of survey respondents display weather data in a similar manner, using dynamically updated data on EMS displays or dashboard visualization or, at a minimum, commercial weather services available in the control center over cable television or the public Internet, mandating that operators receive dynamically updated real-time and forecasted data is consistent with prevailing practice.

Recommendations for Operating Guidelines

RTBPTF is not recommending Operating Guidelines related to Miscellaneous Data at this time.

Areas Requiring More Analysis

RTBPTF is not recommending additional areas for analysis related to Miscellaneous Data.

Examples of Excellence

RTBPTF did not identify any Examples of Excellence related to Miscellaneous Data.

Section 2.0
Reliability Tools for Situational Awareness

Introduction

RTBPTF formulated a list of real-time monitoring and analysis tools/applications commonly used by operators and inquired in the Real-Time Tools Survey about current industry practices associated with these tools.

The basis for the initial list was a report on minimum requirements and best practices for reliability software, presented at a FERC technical conference.[1] The report addressed the following functional areas:

- Network analysis
- Monitoring and visualization
- Real-time enablers
- Operations planning
- Transactions scheduling
- History and forecasting

RTBPTF first narrowed the scope of the list and limited the applications that the task force considered to real-time operator tools; that is, RTBPTF did not consider long-term, medium-term, day-ahead, and training tools even though these tools may be essential for reliability entities. The task force also did not consider real-time tools related to market or economic operations. Special emphasis was placed on real-time tools that could aid operator situational awareness (i.e., reliability tools) because the *Outage Task Force Final Blackout Report* repeatedly identifies operator situational awareness as a key element that needs improvement.

Next, RTBPTF used its collective expertise and experience to formulate a final list of tools to investigate and a precise definition for each. The Real-Time Tools Survey was designed so that different types of entities responsible for the reliable operation of the bulk electric system could describe their use of each tool, so the task force could use the survey results to characterize to the tool's status industry wide. The survey and the subsections below cover following real-time reliability tools for operators:

- **Section 2.1, Alarm Tools** — Alarm tools are applications that emit real-time visible and audible signals to alert operators to events and conditions affecting the state of the bulk electric system. Alarm tools

[1] Macedo, Frank. Consultant to FERC. 2004. *Reliability Software Minimum Requirements & Best Practices*. FERC Technical Conference, July 14. http://www.ferc.gov/EventCalendar/Files/20040716092511-20040714085315-FrankMacedo.pps

can be external, embedded within the SCADA/EMS system, or a combination of both.

- **Section 2.2, Visualization Techniques** — Visualization techniques are a group of user interface applications, tools, and displays that provide, for operators and others, concise visual monitoring and enhanced multiple views of relevant power system data in real time. Visualization techniques help operators monitor and understand system events and/or conditions in neighboring power systems that may affect reliable operations in the operator's portion of the power system.
- **Section 2.3, Network Topology Processor** — The network topology processor (NTP) is a SCADA-based application that determines facility status and station configuration based on breaker and switch status data. The processor converts a nodal network model into a bus-branch model, for use by other applications such as the state estimator. It may perform the same function for study network applications such as power flow.
- **Section 2.4, Topology & Analog Error Detection** — Topology and analog error detection identifies and/or automatically overrides incorrect SCADA breaker and switch statuses, which can support the NTP application and to improve the accuracy and robustness of the state estimator application. It may also identify and/or automatically ignore SCADA analog measurements that are unreasonable or inconsistent with network connectivity.
- **Section 2.5, State Estimator** — The state estimator application performs statistical analysis using a set of imperfect, redundant, telemetered power system data to determine the system's current condition. The system condition or state is a function of several variables: bus voltages, relative phase angles, and tap changing transformer positions. A state estimator can typically identify bad analog telemetry, estimate non-telemetered flows and voltages, and determine actual voltage and thermal violations in observable areas. The state estimator application provides a base case for reliability-analysis applications and input to other system monitoring tools. The state estimator solution is typically used as the base case for other reliability-related applications, such as contingency analysis. In some cases, the state estimator is used primarily as the basis for information communicated to operators regarding power system status; e.g., the state estimator drives the alarm application that alerts operators to power system events.
- **Section 2.6, Contingency Analysis** — The contingency analysis application analyzes the impact on system security of specific, simulated outages (lines, generators, or other equipment) or higher

load, flow, or generation levels. Contingency analysis identifies problems such as line overloads or voltage violations that will occur if a new event (contingency) happens on the system. The state estimator solution is a representation of current system conditions and usually serves as the base case for contingency analysis. The information that contingency analysis generates enables RCs and TOPs to implement mitigation plans in advance of a contingent event such as a line trip. Contingency analysis is used as a real-time application as well as for studying potential scenarios.

- **Section 2.7, Critical Facility Loading Assessment (CFLA)** — A critical facility loading assessment (CFLA) evaluates a set of contingencies and then approximates the post-contingency loading of a set of monitored facilities using telemetered SCADA flows and line outage distribution factors (LODFs). CFLA may be used as a backup application if the state estimator and/or contingency analysis applications fail.
- **Section 2.8, Power Flow** — The power-flow application calculates the state of the electric power system in the form of flows, voltages, and angles, based on load, generation, net interchange, and facility status data. Power-flow applications are available in both on-line and off-line versions. An application that evaluates on-line power flow typically is incorporated into an EMS (or has a direct data feed from an EMS) and utilizes node-breaker topology whereas off-line power flow utilizes models of bus branches and static data. Section 2.8 addresses only on-line power flow.
- **Section 2.9, Study Real-Time Maintenance (SRTM)** — The SRTM function simulates real-time network applications (i.e., topology processor, state estimator, and contingency analysis) and debugs problems without affecting the real-time operation of the applications. An SRTM tool can be an on-line application integrated with the production EMS, an application integrated with a non-production EMS (development, test, dispatcher training simulator system, etc.), or an off-line application.
- **Section 2.10, Voltage Stability Assessment** — Voltage stability analysis (VSA) is an application that executes in near-real time and aids in the determination of system operating limits. VSA is based on an assessment that uses a current state estimator model of the real-time system. VSA may derive minimum voltages at key buses below which voltage collapse may occur under further stress to the system, evaluate whether sufficient stability margins exist for an analyzed base case, provide margins relative to particular stress modes such as transfers or system loading, or provide information on minimum dynamic reactive reserves required in local areas.

- **Section 2.11, Dynamic Stability Assessment —** Dynamic stability assessment (DSA) is an application (or suite of applications) executing in near-real time that aids in determining stability-related system operating limits using a current state estimator model of the real-time system. DSA may also indicate the dynamic stability margin for the most critical fault/contingency condition.
- **Section 2.12, Capacity Assessment —** The capacity assessment (or equivalent) application gives an overview of available generation capacity (MW or Mvar) in real time.
- **Section 2.13, Emergency Tools —** Emergency tools are applications or procedures that operators use when the power system enters or is about to enter an emergency. Several different types of emergency tools were considered in the Real-Time Tools Survey:
    - Residential Load Management or Residential Demand-Side Management tools, which allow curtailment of residential load demand for specific appliances
    - Commercial/Industrial Load Management or Commercial/Industrial Demand-Side Management tools, which allow curtailment of commercial/industrial load
    - Load Reduction by Voltage Reduction – curtailment of demand by voltage reduction on distribution loads
    - Rotating Load Shed – curtailment of demand by triggering/scheduling load shedding
- **Section 2.14, Other Tools (Current and Operational) —** This section reviews other tools (currently available and operational) that are not specifically addressed in the other sections. including:
    - Congestion Management Application - a tool for relieving network congestion within an entity’s service territory using operational means within the entity’s control authority, i.e., generation redispatch, curtailment of economy transactions within the entity’s service area, switching in capacitor banks, opening low-voltage lines. Typically, congestion management is a security-constrained dispatch program, an optimal power-flow program, or an heuristic program that searches for the best solution from a set of options. For an ISO or an RTO, this may be part of the locational marginal pricing (LMP) application.
    - Inter-Regional Real-Time Coordination for Congestion Management Application - may be different from the congestion management application listed above if the entity uses a separate tool for managing congestion caused by transactions that originate and/or terminate outside of the entity’s service area. This may also be the NERC Interchange Distribution

Calculator (IDC) if used for managing congestion that involves curtailing transactions outside of the entity's service territory.

- o Inter-Regional Real-Time Coordination for Market Redispatch – adjusts the market dispatch within the entity's service territory in coordination with adjacent reliability coordinators to manage inter-regional congestion in real time. This tool may be handled by the entity's congestion management application or through a different process.
- o Inter-Regional Voltage Profile Coordination — harmonizes the voltage profiles between two or more regions and may contain features such as wide-area voltage contour visualization, voltage schedule coordination between regions.
- o Short-Term Hydro Scheduling — manages, in real time, deviations from the long-term optimized schedule for reliability reasons (e.g., a response to a disturbance control standard event), acquiring support for localized voltage control.
- o Short-Term Wind Energy Forecasting — predicts and manages, in near-real time, generation accounting for variability of supply from wind energy sources.
- o Short-Term Load Forecasting — predicts short-term (next 0-60 minutes) loads based on parameters such as short-term weather effects, current load. Results could be used for predictive redispatch, look-ahead contingency analysis, awareness of scheduled non-conforming load changes, etc.
- o Short-Term Weather Forecasting — predicts short-term (next 0-60 minutes) extreme weather that may impact operations., i.e. lightning prediction tool, Doppler radar, etc.

Significance to the August 14, 2003 Blackout

The *Outage Task Force Final Blackout Report* concluded, and NERC concurred, that among the initiating causes of the 2003 blackout related to tools were:

- that FirstEnergy (FE) lost functionality of its critical monitoring tools and as a result lacked situational awareness of degraded conditions on its transmission system, and
- that the MISO RC did not provide adequate diagnostic support.

The *Outage Task Force Final Blackout Report* findings related to tools and operator situational awareness were the impetus for the formation of RTBPTF. The discussions of each tool that follows this introduction contain relevant background analysis and information from the *Outage Task Force Final Blackout Report*. For example, discussions that explain the directives given to FE and MISO related to the state estimator and contingency analysis are emphasized in the state estimator and contingency analysis sections below. The objective of these discussions is to introduce the reader to the significance of the RTBPTF recommendations as they relate to the *Outage Task Force Final Blackout Report* recommendations.

Tool Description and Usage

Each reliability tool (or set of tools) addressed in the Real-Time Tools Survey is described in detail in the following subsections. Each tool (or set of tools) is classified according to the industry's usage of it and its perceived importance for operator situational awareness. Most of the tools are commercially available and are generally used as intended. Discussions of each tool include the following:

- An assessment of the tool's availability within the respondent's organization (Is the tool available?)
- An assessment of the tool's usage (Is the tool operational?)
- An assessment of the tool's value for operator situational awareness and reliable operation of interconnected bulk electric system elements (How valuable is the tool for operators?)
- An assessment of the tool's general characteristics, algorithmic approaches, and functional features
- Description of available performance metrics for tool availability or tool solution quality (as applicable) and how they are assessed and used by survey respondents
- Description of the support and maintenance practices related to the tool

RTBPTF Recommendations for New Reliability Standards

RTBPTF approached each tool/application in the following way: given current NERC Reliability Standards how is the tool relevant in aiding operators in complying with monitoring and analysis requirements specified by the standards? Is the tool essential for operators to reliably manage the interconnected bulk electric system (i.e., should the tool be mandatory)?

Based on the survey results and current NERC Reliability Standards, RTBPTF recommends requiring the following monitoring and analysis tools for RCs and TOPs (illustrated in Figure 2.0-1 below):

- Alarm tools
- Telemetry data systems
- Network topology processor
- State estimator
- Contingency analysis

The rationale for recommending each tool as part of the minimum "Reliability Toolbox" is discussed in each of the tool's respective sections as well as in the Reliability Toolbox Rationale and Recommendation section near the beginning of this report. RTBPTF recommends requirements related to tool availability and solution quality (when applicable) for each of the mandatory tools listed above. RTBPTF believes that the mandatory tools listed above are essential for operators to maintain situational awareness and reliable operation of the bulk electric system. These essential tools are a mix of "monitoring" and "analysis" tools and are by no means the only tools that the operators that should use; RTBPTF believes that these are the *minimum* set of tools.

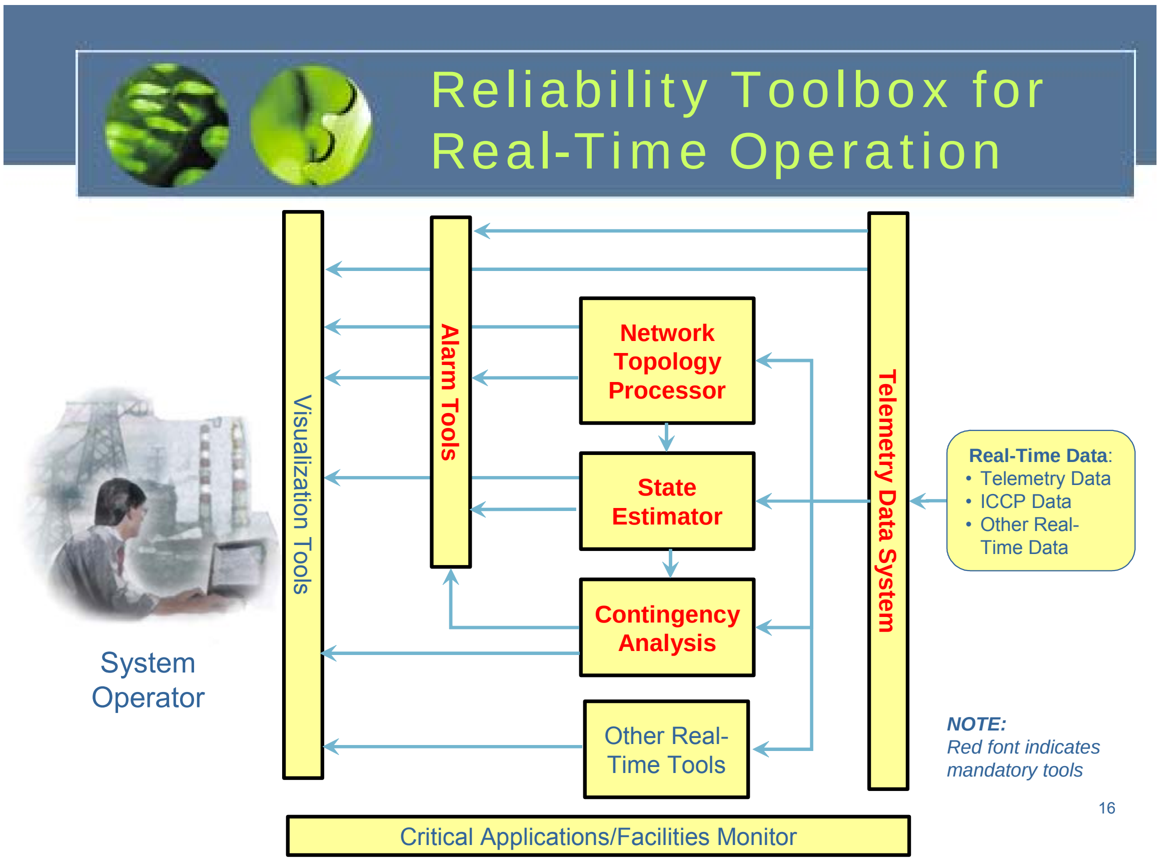

Figure 2.0-1 — The Reliability Toolbox

RTBPTF Recommendations for NERC Operating Guidelines

When there is a prevalent practice related to tool/application usage that supports a NERC Reliability Standard, a recommendation for Operating Guidelines is discussed in the relevant section of this report. In some cases, prevalent functional features that could aid operator situational awareness are recommended as Operating Guidelines.

Section 2.1
Alarm Tools

Definition

Alarm tools are applications that emit real-time visible and audible signals to alert operators to events and conditions affecting the state of the bulk electric system. Alarm tools can be external, embedded within the SCADA/EMS system, or a combination of both.

Background

The *Outage Task Force Final Blackout Report* stresses the importance of alarm tools, noting that “FE did not have additional or back-up monitoring tools to understand or visualize the status of their transmission system to facilitate its operators’ understanding of transmission system conditions after the failure of their primary monitoring/alarming systems.”[2]

The report analyzes FE’S computer problems in detail, with special emphasis on alarm tools. Excerpts of the analysis are quoted below:

> Starting around 14:14 [Eastern Daylight Time] EDT, FE’s control room operators lost the alarm function that provided audible and visual indications when a significant piece of equipment changed from an acceptable to a problematic condition. Shortly thereafter, the EMS system lost a number of its remote control consoles. Next it lost the primary server computer that was hosting the alarm function, and then the backup server such that all functions that were being supported on these servers were stopped at 14:54 EDT. However, for over an hour no one in FE’s control room grasped that their computer systems were not operating properly, even though FE’s Information Technology support staff knew of the problems and were working to solve them, and the absence of alarms and other symptoms offered many clues to the operators of the EMS system’s impaired state. Thus, without a functioning EMS or the knowledge that it had failed, FE’s system operators remained unaware that their electrical system condition was beginning to degrade. Unknowingly, they used the outdated system condition information they did have to discount information from others about growing system problems.[3]

---

[2] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April. page 18.
[3] Ibid., page 52.

Alarm tools are essential for reliability monitoring; operators rely heavily on audible and on-screen alarms as well as alarm logs to detect significant changes in system conditions. The *Outage Task Force Final Blackout Report* observes that alarms are the fundamental means by which operators identify bulk electric system events that need attention. Without alarms, operators may not detect events that signal significant system changes.[4] RTBPTF identifies alarm tools as critical real-time tools. The alarm tools section of the Real-Time Tools Survey attempted to obtain a snapshot of current industry availability and usage of alarm tools.

Summary of Findings

The survey results indicate that nearly all survey respondents have operational alarm tools and consider them "essential" for situational awareness although just over half of all respondents can detect and independently notify operators and support staff when alarm tools are not functioning. Other key results are that the three most widely used functional features of alarm tools are conditional alarming, multiple areas of responsibility, and independent alarm acknowledgment. Survey results also reveal that the failed alarm processor detection feature is not commonly available

As illustrated in Table 2.1-1, nearly all survey respondents (52 out of 53) report that their organizations have operational alarm tools and that these tools are "essential" for situational awareness (50 out of 52). However, fewer than 60 percent of all respondents can detect and independently notify operators and support staff when alarm tools are not functioning.[5]

NOTE: In the columns of all tables in this section that list percentages of respondents, the percentage value is preceded by the number of respondents out of the total that gave the indicated response. For example, "32/38=84%" means that 32 out of a total of 38 respondents, or 84% of respondents, gave the indicated response.

[4] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April. page 52.

[5] The issue of awareness of availability of critical real-time tools is addressed in Section 5.4, Critical Applications Monitoring.

Survey Question	All	RCs	Others
Do you have Alarm Tools?	53/53 = 100%	17/17 = 100%	36/36 = 100%
Are these tools operational?	52/53 = 98%	17/17 = 100%	35/36 = 97%
Do you rate the value (essential) of your Alarm Tools application(s) as a reliability tool for situational awareness?	50/52 = 96%	17/17 = 100%	33/35 = 94%
Do you rate the value (desirable) of your Alarm Tools application(s) as a reliability tool for situational awareness?	2/52 = 4%	0/17 = 0%	2/35 = 6%
Do you rate the value (minimal value) of your Alarm Tools application(s) as a reliability tool for situational awareness?	0/52= 0%	0/17 = 0%	0/35 = 0%
Do you rate the value (no value) of your Alarm Tools application(s) as a reliability tool for situational awareness?	0/52 = 0%	0/17 = 0%	0/35 = 0%

Table 2.1-1 — Availability and Rating of Alarm Tools

Control room personnel are the primary users of alarm tools. However, first-line management and EMS support staff also use alarm tools at a majority of the respondents' locations. System protection and control personnel, field personnel, and systems security personnel use alarm tools at some respondents' locations.

The most common input to alarm tools comes from SCADA/EMS systems, but other applications also provide input. Table 2.1-2 summarizes the most common applications that interface with alarm tools.

What Applications Are Interfaced or Integrated With Your Alarm Tools?	All	RCs	Others
Topology processor	28/52 = 54%	12/17 = 71%	16/35 = 46%
State estimator	32/52 = 62%	12/17 = 71%	20/35 = 47%
Contingency analysis	31/52 = 60%	12/17 = 71%	19/35 = 54%
Artificial intelligence or other high-level summary applications	8/52 = 15%	4/17 = 24%	4/35 = 11%
Station one-line displays	46/52 = 88%	13/17 = 76%	33/35 = 94%
Other(s)	9/52 = 17%	4/17 = 24%	5/35 = 14%

Table 2.1-2 — Applications Typically Interfaced to Alarm Tools

The Real-Time Tools Survey asked respondents to identify their alarm tools' available functional features and to rank the value of each functional feature for situational awareness. Table 2.1-3 summarizes the responses. Blank percentages equal zero.

Functional Feature	All	Reliability Coordinator	Others
Conditional Alarming: Ability to define conditions before issuing an alarm. For example, you would only alarm on a circuit breaker change of state if another circuit breaker is also open.	Available: 28/51=55% Operational: 19/28=68%	Available: 10/17=59% Operational: 9/10=90%	Available: 18/34=53% Operational: 10/18=56%
	Essential: 10/19=53% Desirable: 9/19=47% Minimal: No Value:	Essential: 6/9=67% Desirable: 3/9=33% Minimal: No Value:	Essential: 4/10=40% Desirable:6/10=60% Minimal: No Value:
Paging/Beeping Feature: Ability for the Alarm Tools to trigger pager or automatic cell phone paging	Available: 20/50=40% Operational: 14/19=74%	Available: 7/17=41% Operational: 4/7=57%	Available: 13/33=39% Operational: 10/12=83%
	Essential: 8/14=57% Desirable: 3/14=21% Minimal: 1/14=7% No Value: 2/14=14%	Essential: 3/4=75% Desirable: 1/4=25% Minimal: No Value:	Essential: 5/10=50% Desirable: 2/10=20% Minimal:1/10=10% No Value: 2/10=20%
Multiple Areas of Responsibility: Ability for the Alarm Tools to alarm a single event and deliver it to multiple Operators or multiple areas of responsibility	Available: 41/50=82% Operational: 36/41=88%	Available: 16/17=94% Operational: 14/16=88%	Available: 25/33=76% Operational: 22/25=88%
	Essential: 26/36=72% Desirable: 9/36=25% Minimal: 1/36=3% No Value:	Essential: 10/14=71% Desirable: 4/14=29% Minimal: No Value:	Essential: 16/22=73% Desirable: 5/22=23% Minimal: 1/22=1% No Value:
Independent Alarm Acknowledgment: Ability for Operators from multiple areas of responsibility to acknowledge their alarms independently even if the alarm came from a single event	Available: 26/50=52% Operational: 21/26=81%	Available: 9/17=53% Operational: 8/9=89%	Available: 17/33=52% Operational: 13/17=76%
	Essential: 15/21=71% Desirable: 6/21=29% Minimal: No Value:	Essential: 6/8=75% Desirable: 2/8=25% Minimal: No Value:	Essential: 9/13=69% Desirable: 4/13=31% Minimal: No Value:
Intelligent Alarm Processor: Ability to summarize alarms based on multiple conditions in order to simplify presentation to the Operator and add understanding to the significance of the current situation	Available: 17/50=34% Operational: 14/16=88%	Available: 6/17=35% Operational: 5/6=83%	Available: 11/33=33% Operational: 9/10=90%
	Essential: 10/15=67% Desirable: 4/15=27% Minimal: 1/15=7% No Value:	Essential: 4/5=80% Desirable: 1/5=20% Minimal: No Value:	Essential: 6/10=60% Desirable: 3/10=30% Minimal: 1/10=10% No Value:
Failed Alarm Processor Detection: Ability to detect and independently notify operators and support staff that the alarm processor or Alarm Tools are down and not functioning	Available: 28/49=57% Operational: 27/28=96%	Available: 7/17=41% Operational: 7/7 100%	Available: 21/32=66% Operational: 20/21=95%
	Essential: 22/27=81% Desirable: 4/27=15% Minimal: 1/27=4% No Value:	Essential: 6/7=86% Desirable: 1/7=14% Minimal: No Value:	Essential: 16/20=80% Desirable: 3/20=15% Minimal: 1/20=5% No Value:
Alarm Help Feature: Ability to directly access response procedures from the alarms	Available: 12/49=24% Operational: 11/12=92%	Available: 5/17=29% Operational: 4/5=80%	Available: 7/32=22% Operational: 7/7=100%
	Essential: 3/11=27% Desirable: 8/11=73% Minimal: No Value:	Essential: 1/4=25% Desirable: 3/4=75% Minimal: No Value:	Essential: 2/7=29% Desirable: 5/7=71% Minimal: No Value:

Table 2.1-3 — Functional Features of Alarm Tools

Three functional features are most widely used and identified by most respondents as either “essential” or “desirable” for situational awareness:

- Conditional Alarming — This feature allows the tool to define conditions before issuing an alarm. Eighty-eight percent of respondents who have conditional alarming available use this feature. All users of this feature rate it “essential” (53 percent) or “desirable” (47 percent) for situational awareness.
- Multiple Areas of Responsibility — This feature allows the tool to deliver a single event alarm to multiple operators or multiple areas of responsibility. Sixty-eight percent of respondents who have the multiple areas of

responsibility feature available use it. Most users of this feature (72 percent) rate it “essential” for situational awareness.

- Independent Alarm Acknowledgment — This feature allows operators from multiple areas of responsibility to acknowledge alarms independently even if an alarm came from a single event. Sixty-eight percent of respondents who have the independent alarm acknowledgment feature available use it. Most users of this feature (71 percent) rate it “essential” for situational awareness.

It is somewhat surprising to note that the failed alarm processor detection feature is not commonly available despite the *Outage Task Force Final Blackout Report*’s implicit recognition of the importance of this feature. Most respondents who have this feature available rate it “essential” for situational awareness (81 percent). This functionality is discussed further in Section 5.4, Critical Applications Monitoring.

Recommendations for New Reliability Standards

Alarm tools are essential, providing visual and audible signals in real time to alert operators and others to events affecting the state of the bulk electric system. Alarms may be initiated by information transmitted directly from telemetry data systems or from other applications, such as the state estimator and contingency analysis. Alarms are an essential means of conveying situational awareness to operators. Accordingly, RTBPTF recommends modifications to existing standards to clarify that use of these tools is mandatory (see the Reliability Toolbox Rationale and Recommendation section). The discussions below support RTBPTF’s recommendation to make alarm tools mandatory.

Recommendation – S1

Mandate the following reliability tools as mandatory monitoring and analysis tools

- Alarm Tools
- Telemetry Data Systems
- Network Topology Processor
- State Estimator
- Contingency Analysis

Alarm Tools: Mandatory Monitoring and Analysis Tool

The *Outage Task Force Final Blackout Report* succinctly states the importance of alarm tools:[6]

[6] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April. page 52.

Alarms are a critical function of an EMS, and EMS-generated alarms are the fundamental means by which system operators identify events on the power system that need their attention. Without alarms, events indicating one or more significant system changes can occur but remain undetected by the operator. If an energy management system's alarms are absent, but operators are aware of the situation and the remainder of the its functions are intact, the operators can potentially continue to use the EMS to monitor and exercise control of their power system. In such circumstances, the operators would have to do so via repetitive, continuous manual scanning of numerous data and status points located within the multitude of individual displays available within their EMS. Further, it would be difficult for the operator to identify quickly the most relevant of the many screens available.

Existing NERC reliability standards implicitly assume the use of alarm tools to aid RCs and TOPs in maintaining situational awareness for the bulk electricity system. Specifying alarm tools as part of the Reliability Toolbox[7] eliminates the vagueness in current NERC reliability standards regarding whether alarm tools, as defined, are mandatory.

Recommendation – S7

Specify and measure minimum availability for alarm tools

Alarm tools availability

If alarm tools are mandatory for bulk electric system situational awareness, they must be highly available and redundant. Awareness of alarm tools availability is discussed in the recommendations in Section 5.4, Critical Applications Monitoring. However, a more detailed awareness (via a requirement for alarm tools availability) of alarm tools is necessary than is described in Section 5.4; in particular, awareness of any "stalled" state is critical. The *Outage Task Force Final Blackout Report* states, "[a]fter that time, the FE control room consoles did not receive any further alarms, nor were there any alarms being printed or posted on the EMS's alarm logging facilities. Power system operators rely heavily on audible and on-screen alarms, plus alarm logs, to reveal any significant changes in their system's conditions. After 14:14 EDT on August 14, FE's operators were working under a significant handicap without these tools. However, they were in further jeopardy because they did not know that they were operating without alarms, so that they did not realize that system conditions were changing."[8]

---

[7] See the Reliability Tool Box Rationale and Recommendation section.
[8] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April. page 52.

RTBPTF recommendation

RTBPTF recommends adding the following new requirement to Standard TOP-006 in order to measure alarm tools availability:

PR1. Alarm Tools Availability. Each reliability coordinator and transmission operator shall operate its alarm tools such that the alarm tools shall have at least one test alarm (or "watchdog" alarm) generated and processed at the Telemetry Data System scan rate. This test alarm (or "watchdog" alarm) could originate from a test field device or could be application generated.

Although the NERC standards process might address other factors in considering this recommendation, RTBPTF recommends the following measure for the requirement stated above:

PM1. Each reliability coordinator and transmission operator shall maintain alarm logs demonstrating that the responsible entity's alarm tools application processed test alarms ("watchdog" alarms) according to Requirement PR2.

Rationale

Analysis of the alarm problem encountered by FE during the 2003 blackout suggests that FE's alarm tools essentially "stalled" while processing alarm events; that is, the alarm tools failed to complete the processing of alarms or produce any other valid output. In the meantime, new inputs — system condition data that needed to be reviewed for possible alarms — built up in and then overflowed the input buffers of the process.[9]

RTBPTF believes that a requirement should be established to correct the situation described above; specifically, an alarm tools availability metric should be required to complement the recommendations in Section 5.4, Critical Applications Monitoring.

Recommendation – G1

Identify implementation strategies and specific algorithms for conditional alarming.

Recommendations for New Operating Guidelines

Based on the survey results, three alarm tools features are most commonly used and identified by most respondents as "essential" or "desirable" for situational

[9] Ibid, Pages 53–54.

awareness. Because one of these features, conditional alarming, could easily be implemented similarly by different entities, "rules" for conditional alarming could be included in an operating guideline. The operating guideline for conditional alarming should identify implementation strategies and specific algorithms that could improve the alarms being sent to operators. The "rules" for conditional alarming need to be determined by studying prevailing industry practices before any operating guidelines are set for alarm tools.

The other two commonly used alarm tools features (multiple areas of responsibility and independent alarm acknowledgment) would most likely be customized to the needs of each entity, so a general operating guideline would be of little or no value. The implementation of these features would vary widely depending on the implementation of areas of responsibility of an entity.

Recommendation – A3

Study intelligent alarm processing capability for producing a single accurate view of system status.

Areas Requiring More Analysis

Macedo (2004)[10] identifies as a minimum requirement for alarm tools intelligent alarm processing that allows the application to filter, prioritize, and group alarms. RTBPTF perceives filtering, prioritization, and grouping of alarms as essential features that are inherent in industry-wide tools as defined in this section and understands intelligent alarm processing as an advanced feature that uses algorithms (i.e. artificial intelligence, neural networks) to process raw alarms and identify root causes of alarm avalanches. This functional feature produces compact, simplified alarm information for operators. RTBPTF recommends additional analysis of the industry's intelligent alarm processing capability because survey results indicate that this seemingly essential feature is not commonly used.

The conditional alarming feature could be classified as an elementary form of intelligent alarm processing. As noted above, intelligent alarm processing allows the tool to summarize alarms based on multiple conditions to simplify presentation to the operator and clarify the significance of a current situation. Depending on the level of complexity of monitoring of entity's area of responsibility, a feature such as intelligent alarm processing could aid operators in timely assessment of and response to complex situations. Processed alarms could give operators a single accurate view of system status so that they would

[10] Macedo, Frank. 2004. *Reliability Software: Minimum requirements and Best practices*. FERC Technical Conference. July 14. http://www.ferc.gov/EventCalendar/Files/20040716092511-20040714085315-FrankMacedo.pps

not have to sift through numerous alarms simultaneously. Intelligent alarm processing is currently in use (34 percent of the Real-Time Tools Survey participants have this feature available). A barrier to wide use of this feature could be the difficulty of setting it up (i.e., the difficulty of maintaining the intelligent database of event processing as underlying system topology is modified). RTBPTF proposes that research in the area of intelligent alarm processing be conducted as the basis for practical implementation of this feature by the industry.

Examples of Excellence

The RTBPTF did not identify any Examples of Excellence related to alarm tools.

Section 2.2
Visualization Techniques

Definition

Visualization techniques are a group of user interface applications, tools, or displays that provide concise visual monitoring and enhanced multiple views of relevant power system data in real time to operators and others. Visualization techniques help an operator monitor and understand system events and/or conditions across neighboring power systems that may be affecting reliable operations in the operator's portion of the power system.

Background

The purpose of the visualization techniques section of the Real-Time Tools Survey was to determine typical industry practices or implementation by RCs, TOPs, and BAs of operational visualization tools. The survey attempted to obtain a snapshot of the current state of the industry regarding the availability and usage of certain types of visualization tools. The survey gave special emphasis to the types of visualization tools available to view/monitor bulk electric system elements currently used by reliability entities.

This section of the report summarizes findings from the Real-Time Tools Survey concerning visualization tools. The objective of this summary is to identify the visualization tools that are in wide use and their functionalities. This section also addresses the definition of the terms "wide area" and "wide area view" in the context of existing NERC reliability standards.[11] RTBPTF introduces the concept of the "view-area view boundary," defined as the network model boundary for the "wide area." The task force recommends that NERC establish a uniform formal process to define what constitutes bulk electric system elements included in the "wide area" and corresponding processes to define the "wide area view boundary."

RTBPTF recommends specific modifications to existing IRO and TOP reliability standards that require the use of visualization tools as part of compliance measures for existing NERC reliability standards. RTBPTF also recommends areas requiring further analysis related to the use, technology forums, and development of visualization tools for operators.

Visualization Tools and the 2004 Blackout

The *Outage Task Force Final Blackout Report* concludes that the August 14, 2003 blackout was similar in many ways to previous large-scale blackouts. The

[11] "Wide area" is defined in the NERC Glossary, which can be found at: http://www.nerc.com.

2003 blackout repeated many deficiencies identified in studies of prior large-scale blackouts, including poor vegetation management and operator training practices and a lack of adequate tools to allow operators to visualize system conditions.

The report states that the principal cause of the August 14, 2003 blackout was a lack of situational awareness, which was, in turn, the result of inadequate reliability tools and backup capabilities. The need for improved visualization capabilities over a wide geographic area is a recurrent theme in the blackout investigation. The report also notes that some wide-area tools to aid situational awareness (i.e., real-time phasor measurement systems) have been tested in some regions but are not yet in general use. Improvements in this area will require significant new investments involving existing or emerging technologies.

In the *Outage Task Force Final Blackout Report*, causal analysis of the blackout concludes that FE lacked situational awareness of transmission-line outages and degraded conditions on its own power system. This lack of situational awareness prevented FE system operators from taking corrective actions to return the system to within limits and from notifying MISO and neighboring systems of the degraded system conditions and loss of critical functionality in the control center. One cause for the lack of situational awareness was attributed to FE operators not having an effective alternative by means of which they could easily visualize the overall conditions of the system once their alarm tools application failed. An alternative for readily visualizing overall system conditions, including the status of critical facilities, would have enabled FE operators to become aware of forced transmission-line outages in a timely manner even though the alarms were non-functional. The report also indicates that MISO did not have monitoring tools that provided high-level visualization of the system. A high-level monitoring tool would have enabled MISO operators to view degrading conditions in the FE power system. A dynamic mapboard or other type of display could have provided a system status overview that could have been quickly and easily understood by the operators of both entities.

Chapter 10 of *Outage Task Force Final Blackout Report* presents recommendations to prevent or minimize the scope of future blackouts. The report identifies direct causes and contributing factors that include "inadequate regional-scale visibility over the bulk power system[12] and recommends that NERC evaluate and adopt better real-time tools for operators and reliability coordinators (Recommendation 22). The report further recommends that NERC require that its operating committee give particular attention in its report to the development of guidance to BAs and RCs on the use of automated wide-area visualization display systems and the integrity of data used in those systems. The report identifies a need for improved visualization techniques and intelligent software to analyze conditions, prioritize issues, and recommend actions. These

[12] U.S.-Canada Power System Outage Task Force. 2004. Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations. April. p. 140

technologies should address some of the human factor issues that currently affect control room operators.[13]

Summary of Findings

The survey results indicate that most respondents use visualization tools and consider them essential for situational awareness, but that practice and implementation of visualization tools vary.

The description of findings below addresses the different visualization tools that were reported in the survey.

The results of the Real-Time Tools Survey reveal varying degrees of practice and implementation related to visualization tools. Use of visualization tools is prevalent in the industry (96 percent of the respondents indicated that they have some form of visualization tools), as shown in Table 2.2-1.

Respondent Type	Percentage That Have Visualization Tools Available
All	47/49=96%
RC	17/17=100%
Others	30/32=94%

Table 2.2-1 — Availability of Visualization Tools

As illustrated in Table 2.2-2, the majority of respondents (46/47=98 percent) indicated that they have an operational visualization tools application. Respondents having an operational visualization tools application were asked about the value of their respective visualization tools application as a reliability tool for situational awareness.

[13] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April. p. 159

Respondent Type	Percentage That Have Operational Visualization Tools	Value Placed on Visualization Tools for Enhancing Situational Awareness	
		"Essential"	"Desirable"
All	46/47=98%	38/46=83%	8/46=17%
RC	16/17=94%	15/16=94%	1/16=6%
Others	30/30=100%	23/30=77%	7/30=23%

Table 2.2-2 — Usage and Value of Visualization Tools by Entity Type

The majority of respondents that reported that they have operational visualization tools rated the value of their tools in enhancing situational awareness as either "essential" (83 percent) or "desirable" (17 percent). One respondent commented, "[c]lear concise information is mandatory for proper operator response." There are various types of visualization tools in use by reliability entities to monitor bulk electric system elements and parameters. Visualization tools allow operators to avoid directly viewing large amounts of raw data (telemetry or other real-time reliability tool/application-type data) directly so that operators can efficiently respond to power system problems. Visualization tools organize critical reliability parameters, which allow operators to monitor the information more efficiently.

The methods that visualization tools use to process and display critical reliability parameters depend on information resulting from the processing of raw data. The Real-Time Tools Survey inquired about certain types of visualization tools but did not by any means include a comprehensive list of the different types of visualization tools available to operators. Respondents were also given a chance to describe their own versions of visualization tools if their tools did not fit in any of the types specified in the survey and if their own versions of the tool were worth noting as an example of excellence.

According to the survey results, the data most commonly used by visualization tools are SCADA-type (i.e., telemetry data) data, followed by state estimator-type data. Respondents identified the following types of visualization tools:

- SCADA one-line displays
- State estimator one-line displays
- Study area one-line displays
- Dynamic overview displays
- Dynamic mapboards
- Wide-area visualization tools
- Selectable data trending

- Reactive reserve monitors[14]
- Remedial action scheme (RAS) monitors
- Automatic safety nets
- Transaction impact monitors
- Flowgate monitors

These types of visualization tools are described and discussed in the subsections below.

SCADA One-Line Displays

SCADA one-line displays are dynamic, one-line diagram displays of substations and major power system components that present the real-time status and selected flow, voltage, and other power system data. This is the most common type of visualization tool used today to monitor bulk electric system elements or parameters. Most entities (98 percent) having operational SCADA one-line displays rate this type of visualization tool "essential" (98 percent) for enhancing situational awareness. Table 2.2-3 summarizes the survey results for SCADA one-line displays by respondent type.

Respondent Type	Percentage That Have Operational SCADA One-Line Displays	Value of SCADA One-Line Displays for Enhancing Situational Awareness	
		"Essential"	"Desirable"
All	47/48=98%	46/47=98%	1/47=2%
RC	16/16=100%	16/16=100%	0/16=0%
Others	31/32=97%	30/31=97%	0/31=0%

Table 2.2-3 — Usage and Value of SCADA One-Line Displays by Respondent Type

The majority of respondents (91 percent) noted that their operators view SCADA one-line displays using proprietary SCADA/EMS terminals. Although not as prevalent, web-based SCADA one-line displays, either through a limited private network (28 percent) or through the entity's corporate intranet (19 percent), provide an alternative method of viewing SCADA one-line displays. SCADA/EMS support staff construct most SCADA one-line displays manually using a display editor (91 percent); a minority of entities (17 percent) use

[14] The original name for this type of visualization tool (per the Real-Time Tools Survey) was "Dynamic Reactive Reserve Monitoring" although the intent of this type of visualization was to monitor both dynamic and static sources. Therefore, to eliminate confusion, RTBPTF changed the name of this tool to "reactive reserve monitor" throughout this report.

applications that auto-generate the SCADA one-line displays using a vendor-provided default format.

The survey results indicate that SCADA one-line displays also have the following prevalent characteristics:

- Status values can be overridden by the operator through these displays.
- Analog values can be overridden by the operator through these displays
- Dynamic coloring is used for 1) indicating points in the alarms, 2) switching device positions, 3) indicating bus, line, and transformer statuses, and 4) indicating equipment clearance tags.
- Links are used to navigate to the master index or other one-line displays.
- The displays show SCADA quality codes on status and analog points.
- Although this feature is not as common, important procedures can be linked to selected displays.

Various Types of SCADA One-Line Displays

The survey asked respondents to quantify the relative number (“all,” “most,” “some,” or “none”) of SCADA one-line displays that are available for stations within the respondent’s area of responsibility. There are various types of SCADA one-line displays (including summary displays that use SCADA data), and the survey asked respondents to quantify each type. Table 2.2-4 summarizes the responses for each type of display. The responses indicate the most common types of SCADA one-line displays currently used across the industry. The results correlate to the availability of telemetry data (see Section 1.1) needed for the type of SCADA one-line display.

Type of SCADA One-Line Display	What One-Line Displays are Available for Stations Within Your Area of Responsibility?			
	All	Most	Some	None
SCADA one-line for substations connected at 345-765 kV	38/43=88%			5/43=12%
SCADA one-line for substations connected at 100-230 kV	41/45=91%	4/45=9%		
SCADA one-line for substations connected at below 100 kV	21/46=46%	16/46=35%	7/46=15%	2/46=4%
Summary display(s) showing important flow gates at all substations	21/42=50%	3/42=7%	6/42=14%	12/42=29%
SCADA one-line for generation plants connected at 345-765 kV	36/42=86%			6/42=14%
SCADA one-line for generation plants connected at 100-230 kV	42/45=93%	1/45=2%	1/45=2%	1/45=2%
SCADA one-line for generation plants connected at below 100 kV	32/46=70%	8/46=17%	4/46=9%	2/46=4%
Summary display(s) showing generation from all sources in the area	32/46=70%	9/46=20%	3/46=7%	2/46=4%
Summary display(s) showing switched reactive devices from all sources	33/46=72%	7/46=15%	4/46=9%	2/46=4%

Table 2.2-4 — Summary of Responses — Relative Number of SCADA One-Line Displays Available for Stations Within Respondents’ Areas of Responsibility

Table 2.2-5 illustrates the results for RCs, which are relatively similar to those from the general population.

Type of SCADA One-Line Display	What One-Line Displays are Available for Stations Within Your Area of Responsibility?			
	All	Most	Some	None
SCADA One-Line for Substations Connected at 345-765 kV	15/15=100%			
SCADA One-Line for Substations Connected at 100-230 kV	14/16=88%	2/16=13%		
SCADA One-Line for Substations Connected at below 100 kV	6/16=38%	5/16=31%	4/16=25%	1/16=/6%
Summary display(s) showing important flow gates at all substations	9/16=56%	3/16=19%	2/16=13%	2/16=13%
SCADA One-Line for Generation Plants Connected at 345-765 kV	15/15=100%			
SCADA One-Line for Generation Plants Connected at 100-230 kV	15/16=94%		1/16=6%	
SCADA One-Line for Generation Plants Connected at below 100 kV	12/16=75%	2/16=13%=	2/16=13%	
Summary display(s) showing generation from all sources in the area	12/16=75%	2/16=13%=	1/16=/6%	1/16=6%
Summary display(s) showing switched reactive devices from all sources	10/16=63%	2/16=13%	3/16=19%	1/16=6%

Table 2.2-5 — Summary of Responses — Relative Number of SCADA One-Line Displays Available for Stations within the RC's Area of Responsibility

Respondents were also asked to quantify the relative number of SCADA one-line displays available for stations in the areas adjacent to the respondent's area of responsibility. There are various types of SCADA one-line displays, including summary displays; entities were asked to quantify each type. Table 2.2-6 summarizes the responses for each type. Overall, there are fewer representations of bulk electric system elements on SCADA one-line displays of the areas adjacent to respondents' areas of responsibility compared to representations of locations within respondents' areas of responsibility. Table 2.2-7 summarizes the data for RCs.

Type of SCADA One-Line Display	What One-Line Displays are Available for Stations in the Areas Adjacent to Your Area of Responsibility?			
	All	Most	Some	None
SCADA one-line for substations connected at 345-765 kV	11/43=26%	5/43=12%	20/43=47%	7/43=16%
SCADA one-line for substations connected at 100-230 kV	6/44=14%	6/44=14%	26/44=59%	6/44=14%
SCADA one-line for substations connected at below 100 kV	4/44=9%	4/44=9%	13/44=30%	23/44=52%
Summary display(s) showing important flow gates at all substations	5/41=12%	5/41=12%	10/41=24%	21/41=51%
SCADA one-line for generation plants connected at 345-765 kV	11/44=25%	3/44=7%	14/44=32%	16/44=36%
SCADA one-line for generation plants connected at 100-230 kV	7/44=16%	6/44=14%	17/44=39%	14/44=32%
SCADA one-line for generation plants connected at below 100 kV	6/45=13%	1/45=2%	14/45=31%	24/45=53%
Summary display(s) showing generation from all sources in the area	5/44=11%	5/44=11%	5/44=11%	29/44=66%
Summary display(s) showing switched reactive devices from all sources	6/44=14%		6/44=14%	32/44=73%

Table 2.2-6 — Summary of Responses — Relative Number of SCADA One-Line Displays Available for Stations in Areas Adjacent to Respondents' Areas of Responsibility

Type of SCADA One-Line Display	What One-Line Displays are Available for Stations in the Areas Adjacent to Your Area of Responsibility?			
	All	Most	Some	None
SCADA One-Line for Substations Connected at 345-765 kV	5/14=36%	3/14=21%	5/14=36%	1/14=7%
SCADA One-Line for Substations Connected at 100-230 kV	2/14=14%	4/14=29%	7/14=50%	1/14=7%
SCADA One-Line for Substations Connected at below 100 kV	2/14=14%	1/14=7%	3/14=21%	8/14=57%
Summary display(s) showing important flow gates at all substations	4/14=29	2/14=14%	6/14=43%	2/14=14%

Summary display(s) showing switched reactive devices from all sources	2/15=13%		4/15=27%	9/15=60%

Table 2.2-7 — Summary of Responses — Relative Number of SCADA One-Line Displays Available for Stations in Areas Adjacent to RC's Area of Responsibility

Various Types of Data Displayed on SCADA One-Line Displays

Respondents were asked to quantify the relative numbers of the types of data shown in their SCADA one-line displays for stations located within their area of responsibility. Various types of data are linked to SCADA one-line displays; respondents were asked to quantify the relative number of each data type. Table 2.2-8 summarizes the responses for each data type. The responses indicate the most common types of data linked to SCADA one-line displays across the industry. Breaker statutes and transmission MW/Mvar flows are the most common types of data shown in typical SCADA one-line displays.

Type of Data Displayed in SCADA One-Line Display	What Types of Data are Displayed on One-Line Displays for Stations Located Within Your Area of Responsibility?			
	All	Most	Some	None
Telemetered Breaker/Switch Position (open/close)	35/46=76%	11/46=24%		
Non-telemetered Breaker/Switch Position (open/close)	25/44=57%	18/44=41%		1/44=2%
Bus Voltage Magnitudes	25/46=54%	21/46=46%		
Bus Voltage Phase Angles	2/42=5%	4/42=10%	8/42=19%	28/42=67%
Line End Voltages (synchronizing potential on open line)	12/45=27%	10/45=22%	18/45=40%	5/45=11%
Ampere Flow on Lines and Transformers	13/44=30%	8/44=18%	11/44=25%	12/44=27%
Ampere Flow on Switching Devices	4/44=9%	6/44=14%	17/44=39%	17/44=39%
MW and Mvar flow On Lines and Transformers	22/46=48%	23/46=50%	1/46=2%	
Thermal and Voltage Operating Limits/Ratings	15/45=33%	9/45=20%	6/45=13%	15/45=33%
Incidental Station Alarms (entry, battery, transformer temperature, etc)	11/46=24%	12/46=26%	7/46=15%	16/ 46=35%

Table 2.2-8 — Summary of Responses — Types of data in SCADA One-Line Displays for Stations within Respondents' Areas of Responsibility

State Estimator One-line Displays

State estimator one-line displays are dynamic, one-line diagram displays of substations and major system components that present the state estimator solution for status and selected flow, voltage, and other power system data. Seventy-two percent of respondents have operational state estimator one-line displays. Respondents that have operational state estimator one-line displays rate this type of visualization tool either as “essential” (62%) or “desirable” (38%) for situational awareness. Table 2.2-9 summarizes the results of the survey for one-line displays by entity type. Most respondents view state estimator one-line displays using proprietary SCADA/EMS terminals, and most state estimator one-line displays are constructed from the existing SCADA one-line displays or manually by EMS support staff.

Respondent Type	Percentage That Have Operational State Estimator One-Line Displays	Value of State Estimator One-Line Displays for Enhancing Situational Awareness	
		"Essential"	"Desirable"
All	33/46=72%	18/29=62%	11/29=38%
RC	16/16=100%	12/16=75%	4/16=25%
Others	17/30=57%	6/13=46%	5/14=36%

Table 2.2-9 — Usage and Value of the State Estimator One-Line Displays by Respondent

The survey results indicate that state estimator one-line displays have the following prevalent characteristics:

- Status values can be overridden by the operator through these displays.
- Analog values can be overridden by the operator through these displays.
- Some entities link the state estimator residual values on their state estimator one-line displays.
- Dynamic coloring is used for 1) indicating points in alarm, 2) switching device positions, and 3) indicating bus, line, and transformer statuses.
- Links are used to navigate to the master index or other one-line displays.
- The displays show SCADA quality codes on status and analog points as processed by the state estimator.
- Although this feature is not as common, important procedures are linked to selected displays

Study Area One-line Displays

Study area one-line displays are one-line diagram displays of substations and major system components that present the active study context[15] of status and selected flow, voltage, and other data from the power system model in use. Examples of this type of visualization tool are power-flow one-line displays and contingency analysis one-line displays (for a specified contingency). Seventy-three percent of respondents have operational study area one-line displays. Respondents that have operational study area one-line displays rate this type of visualization tool as either "essential" (70 percent) or "desirable" (30 percent) for situational awareness. Table 2.2-10 summarizes the survey results of for study area one-line displays, by respondent type.

[15] Study context pertains to the output solution of certain power system network applications such as power flow, contingency analysis, etc.

Respondent Type	Percentage That Have Operational Study Area One-Line Displays	Value of Study Area One-Line Displays for Enhancing Situational Awareness	
		"Essential"	**"Desirable"**
All	32/44=73%	21/30=70%	9/30=30%
RC	16/16=100%	12/16=75%	4/16=25%
Others	16/28=57%	9/14=64%	5/14=36%

Table 2.2-10 — Usage and Value of Study Area One-Line Displays by Respondent Type

Study area one-line displays have these prevalent characteristics:

- Study context status values can be changed by the operator through these displays.
- Study context analog values can be changed by the operator through these displays
- Study context solution can be executed by the operator from these displays.
- Dynamic coloring is used for 1) indicating points in alarm, 2) switching device positions, and 3) indicating bus, line, and transformer statuses.
- Links are used to navigate to the master index or other one-line displays.

Dynamic Overview Displays

Dynamic overview displays are one-line and other graphical displays depicting the state, loading, and/or voltage levels over the wider area (or a sub-area within the entity's internal footprint) of the power system. Dynamic overview displays are essentially large SCADA one-line displays. An example of this type of visualization tool is area overview one-line displays, a one-line display that shows a group of electrically connected substations for a specified area. Eighty-two percent of respondents have operational dynamic overview displays. Respondents rate this type of visualization tool as "essential" (56 percent), "desirable" (42 percent), or of "minimal value" (3 percent) for situational awareness. Table 2.2-11 reflects the survey results for dynamic overview displays, by respondent type.

Respondent Type	Percentage That Have Operational Dynamic Overview Displays	Value of Dynamic Overview Displays for Enhancing Situational Awareness	
		"Essential"	"Desirable"
All	36/44=82%	20/36=56%	15/36=42%
RC	16/16=100%	9/16=56%	7/16=44%
Others	20/28=71%	11/20=55%	8/20=40%

Table 2.2-11 —Usage and Value of Dynamic Overview Displays by Respondent Type

Dynamic overview displays have these prevalent characteristics:

- Layered zooming with automatic de-cluttering
- Animated power flow (magnitudes and direction)
- Dynamic coloring for indicating real-time bus, line, and transformer status
- Navigational links to the master index or one-line displays
- Availability for telemetered (SCADA) output
- Continuous projection or display in large format for system operators
- Inclusion of boundary substations/plants adjacent to entity's area of responsibility

The survey asked respondents to quantify the relative number of power system elements (within the entity's area of responsibility) displayed in their dynamic overview displays. Table 2.2-12 summarizes the responses. The responses indicate the level of detail of dynamic overview displays across the industry.

Power System Element	What Power System Elements Within Your Area of Responsibility are Displayed on the System Overview?			
	All	Most	Some	None
Lines operating at 345-765 kV	28/33=85%	2/33=6%	1/33=3%	2/33=6%
Lines operating at 100-230 kV	24/35=69%	6/35=17%	5/35=14%	
Lines operating at below 100 kV	9/35=26%	8/35=23%	5/35=14%	13/35=37%
Transmission level intertie transformer banks	14/34=41%	5/34=15%	7/34=21%	8/34=24%
Transmission level capacitor/reactor banks	19/35=54%	5/35=14%	3/35=9%	8/35=23%
Generation plants 500 MW	24/33=73%	3/33=9%	2/33=6%	4/33=12%
Generation plants 100-500 MW	25/35=71%	2/35=6%	4/35=11%	4/35=11%
Generation plants < 100 MW	16/34=47%	6/34=18%	6/34=18%	6/34=18%
Substation switching devices on lines and transformers	7/33=21%	9/33=27%	8/33=24%	9/33=27%
Substation bus voltages	11/35=31%	18/35=51%	6/35=17%	
Line and transformer flows (MW and MVAR)	9/35=26%	20/35=57%	5/35=14%	1/35=3%

Table 2.2-12 — Summary of Responses — Type of Power System Element included in Dynamic Overview Displays

Dynamic Mapboard

A dynamic mapboard is a stationary, prominently located physical collection of painted lines, status lights, and analog readouts presenting continuous real-time status of important selected components of the power system to operators. It is "dynamic" because the status data for important selected components of the power system are updated in real time. A dynamic mapboard usually complements common SCADA/EMS displays. Sixty-five percent of survey respondents report that they have a dynamic mapboard and rate this type of visualization tool as "essential" while an additional 35 percent rate it "desirable" for enhancing situational awareness. Table 2.2-13 summarizes the survey results for the dynamic mapboard by respondent type. The Real-Time Tools Survey did not ask any questions regarding the extent of the entity's footprint displayed using the dynamic mapboard.

Some respondents indicated in comments that, in lieu of a dynamic mapboard, they use video projection technology (see wide-area visualization tools below) to show the same type of information to their operators.

Respondent Type	Percentage That Have Operational Dynamic Mapboard	Value of Dynamic Mapboard for Enhancing Situational Awareness	
		"Essential"	"Desirable"
All	28/43=65%	17/26=65%	9/26=35%
RC	10/15=67%	5/8=63%	3/8=38%
Others	18/28=64%	12/18=55%	6/18=33%

Table 2.2-13 — Usage and Value of Dynamic Mapboard by Respondent Type

A dynamic mapboard has these prevalent characteristics:

- Mosaic structure for easy accommodations of revisions/changes
- Color/lighting dynamics indicating breaker/switch status
- Digital readouts for presenting critical voltage or flow information
- Availability for telemetered output
- Maintenance of last known state/values if data link and/or SCADA/EMS fails
- Inclusion of boundary substations/plants adjacent to entity's area of responsibility

Wide-Area Visualization Tools

Wide-area visualization tools consist of displays/tools driven by SCADA, EMS, PMU, disturbance recorder, and other technical data collected in real time that present concise information for the "wide area." In general, these display/tools show multiple views of the status of critical facilities within the entity's internal footprint, but they are also used to show views of critical facilities or data from the entity's external footprint that have the potential to adversely impact the internal system (i.e., they cover the "wide area" as defined by the NERC Glossary, which can be viewed at: http://www.nerc.com). Under this definition, dynamic overview displays may be considered wide-area visualization tools. In addition to the traditional SCADA/EMS displays that show critical reliability parameters, wide-area visualization tools use other forms of technology/methodology to present vast amounts of information in a form that allows the operator to quickly and intuitively assess the state of the system. Examples of wide-area visualization technology/techniques include:

- Video or other forms of "big screen" or projection technology (usually in lieu of a traditional dynamic mapboard)
- Smart dashboards (i.e., wide-area status summary displays that show composite data from various applications/tools)
- Displays with extensive animation (i.e., line-flow visualization)[16]
- Contour displays (used to show spatially distributed continuous data)
- Virtual environment visualization[17]
- Data-mining systems[18]

Fifty-two percent of respondents report that they have wide-area visualization tools and rate these tools as either "essential" (55 percent) or "desirable" (45 percent) for enhancing situational awareness. Table 2.2-14 summarizes the survey results for wide-area visualization tools by respondent type.

[16] See http://www.pserc.wisc.edu/ecow/get/publicatio/1999public/etrep05Smaller.pdf
[17] Ibid.
[18] See http://www.infres.enst.fr/~hebrail/publications/hdr/Compstat_2000.pdf

Respondent Type	Percentage That Have Operational Wide-Area Visualization Tools	Value of Wide-Area Visualization Tools for Enhancing Situational Awareness	
		"Essential"	"Desirable"
All	23/44=52%	12/22=55%	10/22=45%
RC	14/16=88%	10/14=71%	4/14=29%
Others	9/28=32%	2/8=25%	6/8=75%

Table 2.2-14 — Usage and Value of Wide-Area Visualization Tools by Respondent Type

The survey also asked entities how they currently use their wide-area visualization tools for monitoring. Table 2.2-15 summarizes the responses.

What Types of Wide-Area Visualization Tools are Available in Your Application(s)?	Respondent Type		
	All	RC	Others
Frequency monitoring	18/22=82%	11/14=79%	7/8= 88%
Natural gas pipeline monitoring	1/22=5%	1/14=7%	0/8=0%
Inter-area phase angle separation monitoring	1/22=5%	0/14=0%	1/8=12%
Multi-area ACE monitoring	13/22=59%	11/14=79%	2/8=25%
Network topology island monitoring	8/22=36%	5/14=36%	3/8=38%
State estimator observable island monitoring	2/22=9%	2/14=14%	0/8=0%
High-speed phasor measurement monitoring	1/22=5%	1/14=7%	0/8=0%
System phase angle monitoring	2/22=9%	1/14=7%	1/8=12%
Voltage profile monitoring	14/22=64%	9/14=64%	5/8=63%
Multi-input artificial intelligence alarming and notification	1/22=5%	1/14=7%	0/8=0%

Table 2.2-15 — Wide-Area Visualization Tools — Current Implementation

The most prevalent uses for wide-area visualization tools are for frequency monitoring, multi-area ACE monitoring, and voltage profile monitoring. The Real-Time Tools Survey did not ask about details or methodology related to how the information is presented to operators. As noted in the Areas Requiring Further Analysis section below, RTBPTF recommends further research and analysis in the usage/implementation of wide-area visualization tools.

Selectable Data Trending

Selectable data trending is a type of visualization tool that can plot graphically selected power system values, using up-to-date data on the plot at a reasonable refresh rate. The majority of survey respondents (91 percent) report that they have selectable data trending and rate this type of visualization tool "essential"

(65 percent) or "desirable" (35 percent) for enhancing situational awareness. According to the survey, actual and/or historical/archived SCADA and application data are the most common types of data represented. Table 2.2-16 summarizes the survey results for selectable data trending by respondent type.

Respondent Type	Percentage That Have Operational Selectable Data Trending	Value of Selectable Data Trending for Enhancing Situational Awareness	
		"Essential"	"Desirable"
All	39/43=91%	18/36=50%	17/36=47%
RC	15/15=100%	8/15=53%	7/15=47%
Others	14/28=50%	10/21=48%	10/21=48%

Table 2.2-16 — Usage and Value of Selectable Data Trending, by Respondent Type

Reactive Reserve Monitor

A reactive reserve monitor uses static and dynamic sources to monitor reactive reserves in local geographic areas or major load centers. This tool can alarm the operator when a generating unit has reached its reactive capability or an area has approached the minimum reactive reserve requirement.[19] This type of tool could also function as the real-time user-interface representation of the documented procedures, practices, or guidelines for maintaining awareness of current and near-term reactive reserve capability (see Section 3.1, Reserve Monitoring). Only 35 percent of respondents report having a reactive reserve monitor tool available for their operators although 59 percent rate it "essential" for situational awareness (see Table 2.2-17).

[19] RTBPTF identifies the minimum reactive reserve requirement as an issue. See Section 3.1, Reserve Monitoring, for this discussion.

Respondent Type	Percentage That Have Operational Reactive Reserve Monitor	Value of Reactive Reserve Monitor for Enhancing Situational Awareness	
		"Essential"	"Desirable"
All	15/43=35%	7/13=54%	5/13=38%
RC	5/15=33%	3/5=60%	2/5=40%
Others	10/28=36%	4/8=50%	3/8=38%

Table 2.2-17 — Usage and Value of Reactive Reserve Monitor, by Respondent Type

Although use of this type of visualization tool is not prevalent, it is worth noting the survey results that identified some of the functional features of reactive reserve monitors, as shown in Table 2.2-18.

Functional Features of Reactive Reserve Monitors	Respondent Type		
	All	RC	Others
Available in study mode	3/14=21%	2/5=40%	1/9=11%
Available in real time	14/14=100%	5/5=100%	9/9=100%
Reserves are monitored area wide	9/14=64%	3/5=60%	6/9=67%
Reserves are monitored intra-area around load center	8/14=57%	4/5=80%	4/9=44%
Unit reactive limits are automatically adjusted based on reactive capability curves and MW output	9/14=64%	3/5=60%	6/9=67%
Unit reactive capability curves are adjusted in real time based on telemetry from the plant	5/14=36%	2/5=40%	3/9=33%
Static reactive capacity of shunt devices is automatically adjusted for real-time voltage	6/14=43%	3/5=60%	3/9=33%
Lagging reserves (total of unused capacitors, etc.) are calculated	9/14=64%	4/5=80%	5/9=56%
Leading reserves (total of unused reactors, etc.) are calculated	5/14=36%	3/5=60%	2/9=22%
Issues an alarm when an area/zone approaches its minimum reactive reserve	7/14=50%	4/5=80%	3/9=33%
Issues an alarm when a unit approaches its minimum/maximum reactive capability	4/14=29%	1/5=20%	3/9=33%
Voltage collapse calculations are part of this tool	2/14=14%	1/5=20%	1/9=11%
Area/Zone reactive demand includes load, loss, and charging Mvar for state estimator solutions	2/14=14%	2/5=40%	0/9=0%
Transmission-level capacitors and reactors are included in reserve calculations	9/14=64%	4/5=80%	5/9=56%
Low-voltage and customer-connected capacitors are included in reserve calculations	1/14=7%	1/5=20%	0/9=0%
Customer-connected motor load and distributed generation are included in reserve calculations	0/14=0%	0/5=0%	0/9=0%

Table 2.2-18 — Functional Features of Reactive Reserve Monitor

Remedial Action Scheme (RAS) Monitor[20]

A remedial action scheme (RAS) monitor provides tools/displays that allow operators to monitor the status of critical power system parameters, measure the proximity of these parameters to the triggering conditions for SPSs or total system failure, and alarms and advises operators regarding actions required to mitigate the pending power system condition. This tool is not in common use; only 38 percent of respondents indicate that they have this capability. However, in contrast to the whole population of respondents, 80 percent of RCs indicate that they have this type of tool available. Respondents that have an operational RAS monitor rate this tool as either "essential" (83 percent) or "desirable" (17 percent) for enhancing situational awareness (see Table 2.2-19).

Respondent Type	Percentage That Have Operational RAS Monitor	Value of RAS Monitor for Enhancing Situational Awareness	
		"Essential"	"Desirable"
All	16/42=38%	12/15=80%	3/15=20%
RC	12/15=80%	9/11=82%	2/11=18%
Others	4/27=15%	3/4=75%	1/4=25%

Table 2.2-19 — Usage and Value of RAS Monitor, by Respondent Type

RAS monitors are not prevalently used. However, it is worth noting the survey results regarding the functional features of this tool. Table 2.2-20 summarizes the survey results.

[20] The terminology was changed from the survey so as not to confuse it with "Remedial Action Scheme" as defined in the glossary section of the "Reliability Standards for the Bulk Electric Systems of North America" document.

Functional Features of RAS Monitor	Type of Respondent		
	All	RC	Others
Operators view the results of this application from SCADA/EMS displays	13/15=87%	9/11=82%	4/4=100%
Operators view the results of this application from other systems	4/15=27%	2/11=18%	2/4=50%
Operators can disable impending SPS based on determination that triggering conditions are false	3/15=20%	2/11=18%	1/4=25%
Alarms and results are based on real-time conditions	11/15=73%	7/11=64%	4/4=100%
Alarms and results are also based on contingency analysis	7/15=47%	6/11=55%	1/4=25%
Static, canned messages are used to inform the operator of recommended action	3/15=20%	2/11=18%	1/4=25%
Artificial Intelligence or multi-level heuristics are used to inform the operator of recommended actions	1/15=7%	1/11=9%	0/4=0%

Table 2.2-20 — Functional Features of RAS Monitor

Automatic Safety Net

An automatic safety net provides the tools/displays for operators to monitor, initiate, or disable triggering of schemes that shed firm load for under-voltage or under-frequency conditions. An automatic safety net could work with a RAS monitor. The automatic safety net is not a prevalent tool; only 37 percent of respondents indicate that they have this tool. Respondents that have operational automatic safety net visualization tools rate them as either "essential" (75 percent) or "desirable" (25 percent) for enhancing situational awareness (see Table 2.2-21).

Respondent Type	Percentage That Have an Operational Automatic Safety Net Visualization Tool	Value of Automatic Safety Net Visualization for Enhancing Situational Awareness	
		Essential	Desirable
All	16/43=37%	10/14=71%	4/14=29%
RC	4/15=27%	4/4=100%	0/4=0%
Others	8/28=29%	6/8=75%	2/8=25%

Table 2.2-21 — Usage and Value of Automatic Safety Net, by Respondent Type

Although the automatic safety net visualization tool is not prevalently used, it is worth noting the survey results regarding the functional features of this tool, which are summarized in Table 2.2-22.

Functional Features an Automatic Safety Net Visualization Tool	Respondent Type		
	All	RC	Others
Warning alarms are issued as conditions approach triggering (if time permits)	8/12=67%	2/4=50%	6/8=75%
Tripping points can be remotely disabled/enabled individually	6/12=50%	3/4=75%	3/8=38%
Tripping points can be remotely disabled/enabled in large groups	5/12=42%	3/4=75%	2/8=25%
Tripping points and/or boundaries are automatically changed as conditions merit	2/12=17%	1/4=25%	1/8=12%

Table 2.2-22 — Functional Features of Automatic Safety Net

Transaction Impact Monitor

A transaction impact monitor provides the tools/displays for operators to monitor scheduled transactions and interchange flows between BAs. The majority (72 percent) of survey respondents indicate that they have this type of tool. Respondents that have an operational transaction impact monitor rate this tool as either “essential” (82 percent), “desirable” (12 percent), or of “minimal” value (5 percent) for enhancing situational awareness. Current implementations of transaction impact monitors use real-time displays, updated for every schedule change. Table 2.2-23 summarizes the results of the survey for transaction impact monitors.

Respondent Type	Percentage That Have Operational Transaction Impact Monitor	Value of Transaction Impact Monitor for Enhancing Situational Awareness	
		“Essential”	“Desirable”
All	28/42=67%	20/27=74%	5/27=19%
RC	14/16=88%	11/14=79%	2/14=14%
Others	14/26=48%	9/13=69%	3/13=23%

Table 2.2-23 — Usage and Value of the Transaction Impact Monitor, by Respondent Type

Flowgate Monitor

A flowgate monitor provides the tools/displays for operators to monitor actual and contingency flows on designated flowgates. The NERC Glossary defines “flowgate” as “[a] designated point on the transmission system through which the Interchange Distribution Calculator calculates the power flow from Interchange Transactions.” This type of visualization tool provides flowgate information to operators; it could run either within or independent of SCADA/EMS systems. Fifty-nine percent of all respondents indicate that they have a flowgate monitor; eighty-one percent of RCs indicate that they have this feature available. Respondents that have an operational flowgate monitor rate this tool as either “essential” (88 percent) or “desirable” (13 percent) for enhancing situational awareness. As currently implemented across the industry, flowgate monitors display real-time data and generate alarms for predicted flowgate overloads. Table 2.2-24 summarizes the results of the survey for flowgate monitors.

Respondent Type	Percentage That Have an Operational Flowgate Monitor	Value of Flowgate Monitor for Enhancing Situational Awareness	
		“Essential”	“Desirable”
All	25/43=58%	21/24=88%	3/24=13%
RC	13/16=81%	12/13=92%	1/13=8%
Others	12/27=44%	9/11=82%	2/11=18

Table 2.2-24 — Usage and Value of Flowgate Monitor, by Respondent Type

Recommendations for New Reliability Standards

RTBPTF believes that operator ability to visualize the status of bulk electric system elements and parameters by means of visualization tools is an essential component of the monitoring process. The Real-Time Tools Survey reveals that entities have used slightly different methodologies and approaches to ensure that they have visualization tools that provide concise, visual monitoring and enhanced multiple views of relevant power system data in real time. Most entities have developed these tools based on their interpretations of operator needs as well as of the implementation of NERC standards.

RTBPTF interprets visualization tools as the user interface layer(s) for the tools/applications necessary to monitor and to maintain the reliability of the bulk electric system. In this report, RTBPTF recommends a mandatory minimum set of monitoring and analysis tools (the Reliability Toolbox; see the Reliability Toolbox Rationale and Recommendation section of this report):

- Alarm tools
- Telemetry data systems
- Network topology processor
- State estimator
- Contingency analysis

Each of these mandatory tools is discussed extensively in its respective sections of the report. Some of the visualization tools discussed in this report are used to present information from one or more of these recommended mandatory applications, which means that these visualization tools must be available. However, RTBPTF believes that it is not necessary for the NERC reliability standards to specify availability standards for these visualization tools in the same context as requiring the availability of the mandatory applications that these visualization tools support. The recommendations within this report focus on mandating the use and availability of the Reliability Toolbox instead of the availability of the user interface (i.e., the corresponding visualization tools.) Requiring the availability of the user interface for the applications is redundant and unnecessary.

Recommendation – S9

Establish a uniform formal process to determine the "wide-area view boundary" and show boundary data/results.

Recommendation – I2

Define wide-area view boundary.

Wide-Area View Boundary

The purpose statement of Standard IRO-003 states "[t]he Reliability Coordinator must have a wide area view of its own Reliability Coordinator Area and that of neighboring Reliability Coordinators." The NERC glossary defines "wide-area" as "[t]he entire Reliability Coordinator Area as well as the critical flow and status information from adjacent Reliability Coordinator Areas as determined by detailed system studies to allow the calculation of Interconnected Reliability Operating Limits." RTBPTF interprets "wide-area view" as the monitoring boundary for reliability coordinators; it is the RC's view of the "wide area." Several RTBPTF recommendations depend on appropriate definition and exchange of information on bulk electric system elements, which in turn, for RCs, requires greater specificity in the definition of the "wide area." For more detail on the issues of wide-area view, see the Introduction Section.

RTBPTF Recommendation

RTBPTF recommends that NERC establish a uniform, formal process to determine the bounds of the "wide area" and the RC's "wide-area view." The *FERC Staff Assessment* states that "[t]he IRO standards do not specify the criteria for identifying critical facilities whose operating status can affect the reliability of neighboring systems and, therefore, hampers effective [w]ide [a]rea visualization."[21]

RTBPTF agrees with the *FERC Staff assessment* and, therefore, recommends that NERC establish a process to determine the critical flow and status information from adjacent reliability coordinator areas based on detailed system studies to allow the calculation of IROLs, to define what constitutes the bounds of the "wide area." This uniform, formal process would clarify the extent and detail required for the "wide area."

RTBPTF also introduces the concept of a "wide-area view boundary." RTBPTF defines "wide-area view boundary" as the network model boundary for the "wide area." For RCs, the "wide-area view boundary" defines the minimum required network model to support the monitoring requirements for the "wide area." This network model should contain all the bulk electric system elements (generators, transmission lines, buses, transformers, breakers, etc.) bounded by the wide-area view boundary. Sections 4.1, Model Characteristics, and 4.2, Modeling Practices and Tools, further discuss issues related to the "wide-area view boundary."

Once this formal definition process is established by NERC, RTBPTF recommends that a new requirement be established under the current Standard IRO-003 that mandates that each RC apply this formal process to identify its bounds for the its wide-area view. The following requirement is recommended:[22]

PR1. Each reliability coordinator shall identify the bounds of its wide area using the NERC-prescribed uniform formal process (Wide-Area Determination Process). Wide-area visualization tools shall show data/information that encompass the wide area.

RTBPTF recommends the following measure for requirement PR1:

PM1. The reliability coordinator shall demonstrate upon request that it is using the NERC-prescribed uniform formal process (Wide-Area Determination Process) to identify the bounds of its wide area as stated in Requirement PR1. Upon request, the reliability coordinator shall produce documentation describing the process and logs/documents demonstrating application of the process.

Rationale

RTBPTF believes that the wide-area view is analogous to the reliability monitoring boundary for RCs. Therefore, all of the tools and processes for the

---

[21] Federal Energy Regulatory Commission (FERC). 2006. *Staff Preliminary Assessment of the North American Electric Reliability Corporation's Proposed Mandatory Reliability Standards*. www.ferc.gov/indus-act/reliability/standards.asp.

[22] Proposed requirements are designated "PR," and proposed measures are designated "PM."

RC to monitor bulk electric system elements and parameters are bounded by the wide area. That is, tools like the state estimator and contingency analysis (and their corresponding power system network models) should be implemented to monitor the RC's wide area. Consequently, network models used by these tools shall cover at a minimum, the wide-area view boundary. A uniform, formal process (Wide-Area Determination Process) eliminates ambiguity for RCs regarding the method of determining the extent of the RC's monitoring boundary (the wide-area view).

Standard IRO-003 mandates that each RC monitor bulk electric system parameters that may have significant impacts upon its RC area and neighboring RC areas. Essentially, each RC is primarily responsible for bulk electric system parameters within its own RC area. However, Standard IRO-003 expands the monitoring requirement to neighboring RC areas based on the wide area.

In Section 1.1, Telemetry Data, RTBPTF recommends that each RC develop and maintain a list of specific bulk electric system elements (generators, transmission lines, buses, transformers, breakers, etc.) within its RC area (the Bulk Electric System Elements List). RTBPTF recommended that the Bulk Electric System Elements List contain the bulk electric system elements within the RC's area necessary for identifying potential or actual SOL or IROL violations within the RC area. Once each RC produces a Bulk Electric System Elements List, RTBPTF believes that this list could be the basis of the uniform, formal process being recommended in proposed requirement PR1 for determining the bounds of the wide area as well as the modeling characteristics for the wide-area view boundary.

If each RC has in its possession its own Bulk Electric System Elements list and is actively monitoring these elements within its own RC area, adjacent RCs could request access to a subset of the elements contained in each adjacent RC's Bulk Electric System Elements Lists. The requesting RC shall use the uniform, formal process to determine extent of the subset of the data it needs. This subset of bulk electric system elements from each adjacent RC's Bulk Electric System Elements List together with the RC's own Bulk Electric System Elements List would then define the bulk electric system elements and parameters for the RC's wide area. Figure 2.2-1 illustrates the concept of the "wide area" as the RC's monitoring boundary.

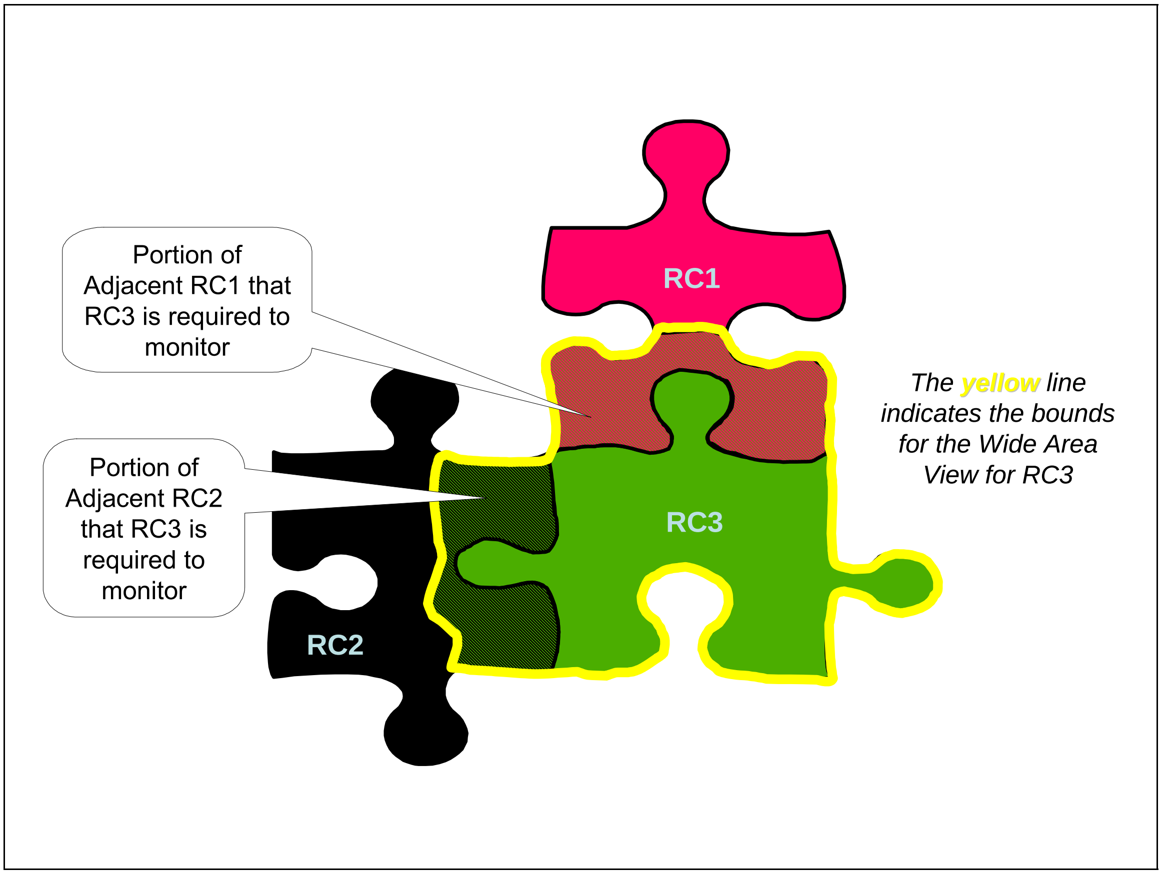

Figure 2.2-1 — Illustration of Wide-Area Concept Related to Monitoring Boundaries for RCs

Usage of Visualization Tools as Measures for Compliance

RTBPTF recommends adding/enhancing measures to require the usage of applicable visualization tools necessary for compliance with existing NERC reliability standards. RTBPTF believes that active demonstration of the usage of visualization tools should be used as measures of compliance with some existing standards. This emphasizes the use of visualization tools to aid reliability entities in "monitoring" bulk electric system elements and parameters.

The existing NERC reliability standards listed below require reliability entities to "monitor" bulk electric system elements and parameters. RTBPTF believes that the word "monitor" does not imply viewing large amounts of raw telemetered or application data. Reliability entities should use visualization tools to concisely organize information as a means to monitor bulk electric system elements and parameters. Visualization tools are highly dependent upon the host application's data (telemetry or application specific) that are provided to each type of visualization tool.

NERC Reliability Standard IRO-003, Reliability Coordination — Wide Area View

Standard IRO-003 states that the RC must have a wide-area view of its own RC area and that of neighboring RCs. Requirement R1 states, "[e]ach Reliability Coordinator shall monitor all Bulk Electric System facilities, which may include sub-transmission information, within its Reliability Coordinator Area and adjacent Reliability Coordinator Areas, as necessary, to ensure that, at any time, regardless of prior planned or unplanned events, the Reliability Coordinator is able to determine any potential System Operating Limit and Interconnection Reliability Operating Limit violations within its Reliability Coordinator Area." Requirement R2 states, "[e]ach Reliability Coordinator shall know the current status of all critical facilities whose failure, degradation or disconnection could result in an SOL or IROL violation. Reliability Coordinators shall also know the status of any facilities that may be required to assist area restoration objectives."

RTBPTF Recommendation

Standard IRO-003 requires a wide-area view for RCs, but it lacks specificity on the measures. RTBPTF recommends development of measures for the requirements specified by Standard IRO-003. The measures for compliance should include verification, through active demonstration, of the usage of visualization tools by operators to fulfill the requirements of the Standard IRO-003.

Once the bounds of the "wide area" are established, each RC shall be required to demonstrate the use of adequate visualization tools and/or summary displays (as appropriate) to comply with the "wide-area view" standard, as mandated by Standard IRO-003. Each RC shall demonstrate, at a minimum, the existence and usage of specific set of visualization tools and/or summary displays (as appropriate) corresponding for each requirement per Standard IRO-003 (see Table 2.2-25 below). As shown in Table 2.2-25, RTBPTF recommends a measure for each requirement in Standard IRO-003.

Standard IRO-003 Requirement[23]	Recommended Measures
R1. Each Reliability Coordinator shall monitor all Bulk Electric System facilities, which may include sub-transmission information, within its Reliability Coordinator Area and adjacent Reliability Coordinator Areas, as necessary to ensure that, at any time, regardless of prior planned or unplanned events, the Reliability Coordinator is able to determine any potential System Operating Limit and Interconnection Reliability Operating Limit violations within its Reliability Coordinator Area.	RTBPTF recommends that the following measure for Requirement R1.[24] PM1. Each reliability coordinator shall demonstrate the active use of visualization tools and summary displays listed below to comply with Requirement R1. Each of these visualization tools and summary displays shall show information within the reliability coordinator's wide area. a. Contingency Analysis Summary Displays b. Dynamic Overview Displays or Dynamic Mapboard c. Wide-Area Visualization Tools Rationale: RTBPTF interprets the determination of "any potential System Operating Limit and Interconnection Reliability Operating Limit violations" as the output solution of the contingency analysis application. RTBPTF recommends contingency analysis as a mandatory tool for reliability coordinators. At a minimum, Requirement R1 requires the demonstration and usage of the contingency analysis application and its related summary displays and output solution. Section 2.6 of this report, Contingency Analysis, discusses the recommendations for the contingency analysis application. Requirement R1 also implies the demonstration and usage of the following list of visualization tools[25] and summary displays for bulk electric system elements within the reliability coordinator's wide area. a. Contingency Analysis Summary Displays b. Dynamic Overview Displays or Dynamic Mapboard c. Wide Area Visualization Tools The Real-Time Tools Survey indicates prevalent practice concerning dynamic overview displays (100%), dynamic mapboard (67%), and wide-area visualization tools (88%) among reliability coordinators. RTBPTF believes that mandating that RCs use wide-area visualization tools and either dynamic overview displays or a dynamic mapboard gives RCs the situational awareness capability mandated by Requirement R1. The scope of the use of these visualization tools is strongly noted by RTBPTF to encompass the RC's wide area. It is not sufficient just to show the RC area.

[23] Each requirement here is stated verbatim from the current Standard IRO-003.
[24] The numbering scheme for these proposed measures (PM) coincides with the existing requirements – e.g., the proposed measure for Requirement R1 is numbered PM1.
[25] The definitions of each type of visualization tool are discussed in the Summary of Findings section above.

Standard IRO-003 Requirement[23]	Recommended Measures
R2. Each Reliability Coordinator shall know the current status of all critical facilities whose failure, degradation or disconnection could result in an SOL or IROL violation. Reliability Coordinators shall also know the status of any facilities that may be required to assist area restoration objectives.	RTBPTF recommends that the following measure for Requirement R2. PM2. Each reliability coordinator shall demonstrate the active use of contingency analysis summary displays to comply with Requirement R2. These summary displays shall show information within the reliability coordinator's wide area. <u>Rationale:</u> RTBPTF interprets the knowledge of "current status of all critical facilities whose failure, degradation or disconnection could result in an SOL or IROL violation" as the output solution of the contingency analysis application. At a minimum, this requires demonstration and usage of the contingency analysis application and its related displays and output solution. Section 2.6 of this report, Contingency Analysis, discusses the recommendations for the contingency analysis application. The second part of this requirement ("status of any facilities that may be required to assist area restoration objectives") is discussed in Section 3.7, Blackstart Capability, of this report.

Table 2.2-25 — Recommended Measures for Standard IRO-003

NERC Reliability Standard IRO-002, Reliability Coordination — Facilities

Standard IRO-002 states that RCs need information, tools, and other capabilities to perform their responsibilities. Requirement R7 of the standard requires that each RC have adequate analysis tools such as state estimation, pre- and post-contingency analysis capabilities (thermal, stability, and voltage), and wide-area overview displays.

Recommendation – S10

Develop compliance measures for verification of the usage of "wide-area overview display" visualization tools.

RTBPTF Recommendation

Standard IRO-002 is specific in requiring RCs to have "wide-area overview displays," but it lacks specificity regarding measures. RTBPTF recommends the development of a measure for the requirements specified in Standard IRO-002 (Requirement R7). The measure for compliance includes verification, through the active demonstration of the usage of visualization tools by the RC to fulfill the "wide-area overview display" requirement of the standard mentioned above. RTBPTF recommends the following measure for Requirement R7:[26]

[26] The numbering scheme for these proposed measures (PM) coincides with the existing requirements – e.g., the proposed measure for Requirement R7 is numbered PM7. Also,

PM7. Each reliability coordinator shall demonstrate the active use of visualization tools and summary displays listed below to comply with Requirement R7. Each of these visualization tools and summary displays shall show information within the reliability coordinator's wide area.

a. Dynamic Overview Displays or Dynamic Mapboard
b. Wide Area Visualization Tools

Rationale

The rationale for this measure is the same as for Requirement R1 of Standard IRO-003. This recommended measure makes clear how to comply with the "wide-area view overview display" Requirement R7.

NERC Reliability Standard IRO-005 — Reliability Coordination — Current Day Operations

The standard's purpose states, "the Reliability Coordinator must be continuously aware of conditions within its Reliability Coordinator Area and include this information in its reliability assessments. The Reliability Coordinator must monitor Bulk Electric System parameters that may have significant impacts upon the Reliability Coordinator Area and neighboring Reliability Coordinator Areas."

Requirement R1 states that each reliability coordinator shall monitor its reliability coordinator area parameters. The subrequirements are listed below verbatim from Standard IRO-005 (Requirement R1):

R1.1. Current status of Bulk Electric System elements (transmission or generation including critical auxiliaries such as Automatic Voltage Regulators and Special Protection Systems) and system loading.
R1.2. Current pre-contingency element conditions (voltage, thermal, or stability), including any applicable mitigation plans to alleviate SOL or IROL violations, including the plan's viability and scope.
R1.3. Current post-contingency element conditions (voltage, thermal, or stability), including any applicable mitigation plans to alleviate SOL or IROL violations, including the plan's viability and scope.
R1.4. System real and reactive reserves (actual versus required).
R1.5. Capacity and energy adequacy conditions.
R1.6. Current ACE for all its Balancing Authorities.
R1.7. Current local or Transmission Loading Relief procedures in effect.
R1.8. Planned generation dispatches.
R1.9. Planned transmission or generation outages.
R1.10. Contingency events.

Requirement R7 is also discussed in other sections (for mandatory tools) with additional measures recommended by RTBPTF.

RTBPTF Recommendation

RTBPTF recommends that each RC demonstrate the use of adequate visualization tools and/or summary displays (as appropriate) to fulfill the monitoring requirements for each of the items listed in Requirement R1 of Standard IRO-005. Each RC shall demonstrate easily accessible visualization tools and/or summary displays (as appropriate) that show the appropriate information as specified by each sub-requirement under Requirement R1. Note that this is in addition to the measures recommended in Section 1.1, Telemetry Data.

RTBPTF recommends addition of measures based on demonstrated usage of visualization tools and/or summary displays (as appropriate) to provide clarity for reliability coordinators regarding how to comply with Standard IRO-005 (Requirement 1). As shown in Table 2.2-26, most of the sub-requirements give the reliability coordinator the flexibility of either demonstrating the active use of summary displays (as appropriate) based on data from other applications/tools or demonstrating the active use of the specified visualization tool(s) for a particular sub-requirement. Requirement R1.1 is the only sub-requirement that mandates that the RC demonstrate use of specific types of visualization tools. In most cases, summary displays are appropriate to fulfill the other sub-requirements (i.e., Requirement 1.2-Requirement 1.7 and Requirement 1.10).

Standard IRO-003, Requirement R1 Sub-requirements	Recommended Measures
R1.1. Current status of Bulk Electric System elements (transmission or generation including critical auxiliaries such as Automatic Voltage Regulators and Special Protection Systems) and system loading.	RTBPTF recommends the following measure for Requirement R1.1:[27] PM1.1. Each reliability coordinator shall demonstrate the active use of the visualization tools or summary displays listed below to comply with Requirement R1.1. Each of these visualization tools and summary displays shall show information within the reliability coordinator's wide area. a. Dynamic Overview Displays or Dynamic Mapboard b. Wide-Area Visualization Tools c. Remedial Action Scheme Monitor or Automatic Safety Net <u>Rationale:</u> Note that recommended measures regarding the monitoring requirement for the "current status of Bulk Electric System elements" as mandated by Requirement R1.1 are also thoroughly discussed in Section 1.1, Telemetry Data. The Real-Time Tools Survey indicates that, among RCs, dynamic overview displays are widely used (100%), as are dynamic mapboard (67%), and wide-area visualization tools (88%). RTBPTF believes that mandating that RCs use wide-area visualization tools <u>and</u> either dynamic overview displays or dynamic mapboards will give RCs the situational awareness capability mandated by Requirement R1.1 to monitor "current status of Bulk Electric System elements." For example, a display containing the all the RC area generating units with their corresponding AVR status could demonstrate usage of wide-area visualization tools. RTBPTF also believes that Requirement R.1.1 mandates that RCs have situational awareness of the status of SPSs. RTBPTF interprets this mandate to mean that RCs must use either a RAS monitor or automatic safety net visualization tools. The Real-Time Tools Survey indicates that RAS monitors are commonly used (88%), and automatic safety nets are not (27%). RTBPTF believes demonstrated use of either of the two tools could be used to demonstrate active usage of visualization tools for situational awareness of RASs.

[27] The numbering scheme for these proposed measures (PM) coincides with the existing requirements – e.g., the proposed measure for Requirement R1.1 is numbered PM1.1.

<table>
<tr><th>Standard IRO-003, Requirement R1 Sub-requirements</th><th>Recommended Measures</th></tr>
<tr><td>R1.2. Current pre-contingency element conditions (voltage, thermal, or stability), including any applicable mitigation plans to alleviate SOL or IROL violations, including the plan’s viability and scope.</td><td>RTBPTF recommends the following measure for Requirement R1.2:

PM1.2. Each reliability coordinator shall demonstrate the active use of the visualization tools or summary displays listed below to comply with Requirement R1.2. Each of these visualization tools and summary displays shall show information within the reliability coordinator’s wide area.
a. State estimator solution summary displays or contingency analysis summary displays
b. Wide-area visualization tools containing the state estimator solution or the base-case solution of the contingency analysis application

<u>Rationale:</u>

RTBPTF interprets “current pre-contingency element conditions” as the state estimator solution or the base-case solution of the contingency analysis application. Section 2.5 of this report, State Estimator, discusses the recommendations for the state estimator application. Section 2.6 of this report, Contingency Analysis, discusses the recommendations for the contingency analysis application.

In addition, RTBPTF recommends that the RC be required to demonstrate the active use of wide-area visualization tools containing the state estimator solution or the base-case solution of the contingency analysis application. Wide-area visualization tools would aid RCs in focusing on important parameters/elements based on the state estimator solution or the base-case solution of the contingency analysis application.</td></tr>
<tr><td>R1.3. Current post-contingency element conditions (voltage, thermal, or stability), including any applicable mitigation plans to alleviate SOL or IROL violations, including the plan’s viability and scope.</td><td>RTBPTF recommends the following measure for Requirement R1.3:

PM1.3. Each reliability coordinator shall demonstrate the active use of the visualization tools or summary displays listed below to comply with Requirement R1.3. Each of these visualization tools and summary displays shall show information within the reliability coordinator’s wide area.
a. Contingency analysis summary displays
b. Wide-area visualization tools containing output solution of the contingency analysis application

<u>Rationale:</u>

RTBPTF interprets “current post-contingency element conditions” as the output solution of the contingency analysis application. Section 2.6 of this report, Contingency Analysis, discusses the recommendations for the contingency analysis application.

In addition, RTBPTF recommends that the RC be required to demonstrate the active use of wide-area visualization tools containing the output solution of the contingency analysis application. Wide-area visualization tools would aid RCs in focusing on important parameters/elements based on the output solution of the contingency analysis application.</td></tr>
</table>

Standard IRO-003, Requirement R1 Sub-requirements	Recommended Measures
R1.4. System real and reactive reserves (actual versus required)	RTBPTF recommends the following measure for Requirement R1.4: PM1.4. Each reliability coordinator shall demonstrate the active use of the visualization tools or summary displays listed below to comply with Requirement R1.4. Each of these visualization tools and summary displays shall show information within the reliability coordinator's wide area. a. Wide-area visualization tools containing output of operating reserve calculations b. Reactive reserve monitor or wide-area visualization tools containing output of reactive reserve calculations <u>Rationale:</u> The "real reserves" are covered by the balancing resources and demand standards and termed "operating reserves." RTBPTF recommends that RCs be required to demonstrate the active use of wide-area visualization tools or summary displays (as appropriate) based on the output of operating reserve calculations in order to comply with the "monitoring" requirements of Requirement R1.4. Section 3.1, Reserve Monitoring, discusses recommendations for reserve monitoring. RTBPTF interprets "reactive reserves (actual versus required)" as the output of the reactive reserve monitor visualization tool for monitoring the status of reactive resources. This visualization tool monitors reactive resources (dynamic and/or static) to determine whether they are sufficient based on current conditions. It has the ability to alarm the operator when either a unit in the area has reached its reactive capability or there are insufficient reactive resources (dynamic and/or static) for an area. RTBPTF recommends that the RC be required to demonstrate the active use of the reactive reserve monitor visualization tool or an equivalent wide-area visualization tool or summary displays (as appropriate) based on the output of reactive reserve calculation as discussed in Section 3.1, Reserve Monitoring.

Standard IRO-003, Requirement R1 Sub-requirements	Recommended Measures
R1.5. Capacity and energy adequacy conditions	RTBPTF recommends the following measure for Requirement R1.5: PM1.5. Each reliability coordinator shall demonstrate the active use of the visualization tools or summary displays listed below to comply with Requirement R1.5. Each of these visualization tools and summary displays shall show information within the reliability coordinator's wide area. a. Capacity assessment application summary displays or wide-area visualization tools containing output of the capacity assessment application. <u>Rationale:</u> RTBPTF interprets "capacity and energy adequacy conditions" as the output of the capacity assessment application. This application gives an overview of available generation capacity (MW or Mvar) in real-time. Section 2.12 of this report, Capacity Assessment, discusses recommendations for the capacity assessment application. RTBPTF recommends that RCs be required to demonstrate the active use of the capacity assessment application (with its corresponding summary displays) or an equivalent wide-area visualization tool that shows capacity and energy adequacy conditions.
R1.6. Current ACE for all Balancing Authorities	RTBPTF recommends the following measure for Requirement R1.6: a. Each reliability coordinator shall demonstrate the active use of the visualization tools or summary displays listed below to comply with Requirement R1.6. The visualization tools or summary displays shall contain the current ACE for all balancing authorities within the reliability coordinator area. <u>Rationale:</u> The current ACE for all of the RC's BAs is obtainable as ICCP-specific data. Compliance may be demonstrated by each RC showing the monitoring (through ICCP data exchange or direct telemetry methods) of the current ACE for all its BAs. Current ACE data are also required per Standard TOP-005. In addition, RTBPTF recommends that the RC be required to demonstrate the active usage of equivalent wide-area visualization tools or summary displays (as appropriate) that show ACE data of balancing authorities within the RC area.
R1.7. Current local or Transmission Loading Relief procedures in effect	RTBPTF is not recommending any measures requiring any visualization tool for Requirement R1.7. Section 2.14 of this report, Other Tools (Current and Operational), discusses the congestion management application, inter-regional real-time coordination for congestion management application, and inter-regional real-time coordination for market redispatch application.
R1.8. Planned generation dispatches	Not within the scope of RTBPTF
R1.9. Planned transmission or generation outages	Not within the scope of RTBPTF

Standard IRO-003, Requirement R1 Sub-requirements	Recommended Measures
R1.10. Contingency events	Requirement R1.1 addresses the continual monitoring of bulk electric system whereas Requirement R1.10 addresses event monitoring. When a critical facility (considered a contingent element) is unavailable, this may be a result of multiple bulk electric system elements indicating a change in status. For example, when a 230-kV transmission line is unavailable (a contingency event), this may be a result of transmission circuit breakers showing a status open. RTBPTF interprets the monitoring of "contingency events" as the output of alarm tools. RTBPTF is not recommending any measures related to visualization tools usage for Requirement R1.10. Section 2.1, Alarm Tools, discusses recommendations for alarm tools.

Table 2.2-26 — Recommended Measures for IRO-005, Requirement 1

NERC Reliability Standard TOP-006 — Monitoring System Conditions

Standard TOP-006 exists, "[t]o ensure critical reliability parameters are monitored in real-time." Requirement R2 states, "[e]ach Reliability Coordinator, Transmission Operator, and Balancing Authority shall monitor applicable transmission line status, real and reactive power flows, voltage, load-tap-changer settings, and status of rotating and static reactive resources."

RTBPTF Recommendation

The requirement to use visualization tools is not limited to RCs but also applies to other reliability entities. In fact, the *Outage Task Force Final Blackout Report* attributes the lack of situational awareness by TOP FE's operators to the lack of an effective alternative to easily visualize the overall conditions once FE's alarm tools failed. An alternative means to readily visualizing overall system conditions, including the status of critical facilities, would have enabled FE operators to become aware of forced transmission-line outages in a timely manner even though the alarms were non-functional.

RTBPTF recommends the following measure for Standard TOP-006 (Requirement R2):[28]

PM2. Each reliability coordinator, transmission operator, and balancing authority shall demonstrate, at a minimum, the existence and usage of the following set of visualization tools and/or displays as a measure for compliance with Standard TOP-006 (Requirement 2):

a. Dynamic overview displays or dynamic mapboard
b. Reactive reserve monitor
c. Remedial action scheme monitor or automatic safety net

[28] The numbering scheme for these proposed measures (PM) coincides with the existing requirements – e.g., the proposed measure for Requirement R2 is numbered PM2.

Rationale

The rationale for Standard TOP-006, Requirement R2 is the same as for Standard IRO-003, Requirement R1 above. This is essentially the same requirement extended to TOPs and BAs.

Recommendation – G2

Consider human factors, ergonomics and maintenance/support issues in implementing visualization tools.

Recommendations for New Operating Guidelines

The implementation of different types of visualization tools would most likely be a customized effort by each entity, so a general operating guideline for each type of visualization tool would be of little or no value. Therefore, RTBPTF is not recommending any operating guidelines specifying which type of visualization tools to use/implement. However, numerous existing research studies/reports in the area of visualization and user interface could be used by entities in designing and implementing their visualization tools. Issues to consider in implementing visualization tools include, but are not limited to, the following:

- Human factors, ergonomics
- Industry adoption of standardized or common presentation of data
- Technical innovations in visualization tools
- Maintenance/support issues

Features of Wide-Area Visualization Tools

In the area of wide-area visualization tools, the Real-Time Tools Survey provides insight regarding desired features of certain industry implementations. These features are worthy of consideration by entities implementing wide-area visualization tools. Functional features to consider in implementing wide-area visualization tools include, but are not limited to, the following:

- Capability to render information using conventional graphing techniques (e.g., pie charts, flashing lines, etc), as well as rendering information using more advanced techniques (e.g., contouring of voltage data, reliability hotspots, etc.)
- Capability to link wide-area visualization tools to alarm tools.
- Capability to mix data from different sources (e.g., telemetry system data with state estimator solution data)
- Capability to present electric system data either geographically or through a schematic representation

- Capability to automatically create a visual representation of the entity's network model; i.e., the wide-area visualization tool is driven by the network model.

Recommendation – A4

Conduct research to assess current technology and practices related to the use and application of visualization tools

Areas Requiring Further Analysis

RTBPTF recommends that NERC, with the help of other research (or government) entities, continue to assess current technology and practices related to the use and application of visualization tools. RTBPTF also notes that Recommendation 13 of the *Outage Task Force Final Blackout Report* states, "DOE should expand its research programs on reliability-related tools and technologies. More investment in research is needed to improve grid reliability, with particular attention to improving the capabilities and tools for system monitoring and management." Items to be included in this research related to visualization tools are:

- Development of practical real-time applications for wide-area system monitoring using phasor measurements and other synchronized measuring devices, including post-disturbance applications
- Development and use of enhanced techniques for modeling and simulation of contingencies, blackouts, and other grid-related disturbances
- Development of practical human factors guidelines for power system control centers

To reiterate, the *Outage Task Force Final Blackout Report* listed the following recommendations from previous investigations concerning visualization tools[29]:

- In the control center, use a dynamic line loading and outage display board to provide operating personnel with rapid and comprehensive information about the facilities available and the operating condition of each facility in service.
- Give control centers the capability to display to system operators computer-generated alternative actions specific to the immediate situation, together with expected results of each action.

[29] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April. p. 108.

Recommendation – A5

Establish a Visualization Tools Working Group (VTWG) to foster and facilitate sharing of best practices.

RTBPTF also recommends the following for NERC's consideration:

- Establish a Visualization Tools Working Group (VTWG) to foster and facilitate sharing of best practices within the industry for the use of visualization tools. This working group could continue to recommend and develop standards and operating guidelines in the area of best methods and practices in presenting information to operators.
- Establish industry and technical forums that involve academic, research organizations, and other organizations to aid and guide the industry in the area of visualization tools.

Examples of Excellence

With visualization tools, the following entities have taken slightly different approaches to ensure that they have user interfaces that provide concise, visual monitoring and enhanced multiple views of relevant power system data in real time. These visualization tools are available to operators to help them monitor and better understand system events and/or conditions across power systems that may be affecting reliable operation in their part of the power system. Visualization tools are provided to the operators to maintain or enhance their situational awareness.

RTBPTF cites the implementation of the facilitated transaction checkout (FTC) tool by all balancing authorities within the Northeast Power Coordinating Council as an example of excellence (See EOE-4 in Appendix E). FTC is a message structure that enables neighboring reliability entities to query each other's interchange transaction stack and perform an automated comparison prior to performing verbal checkout, thus improving the accuracy associated with transaction checkout.

RTBPTF cites the implementation of PowerWorld Retriever by Southwest Power Pool to provide a system overview (i.e., voltage contouring), as well as alarms using pie charts and flashing lines, as an example of excellence (See EOE-5 in Appendix E).

RTBPTF cites the implementation of an expansive wide-area overview display with underlying BA and one-line displays, including flowgate and reactive monitoring displays, by MISO as an example of excellence (See EOE-6 in Appendix E).

RTBPTF cites American Transmission Company's use of an application that interfaces directly with its EMS to provide system operators with a dynamic wide-area overview of its network topology as well as state estimation of the neighboring systems as an example of excellence (See EOE-7 in Appendix E).

Section 2.3
Network Topology Processor

Definition

The network topology processor (NTP) is a SCADA-based application that determines facility status and station configuration based on breaker and switch status data. The processor converts a nodal network model into a bus-branch model, for use by other applications such as the state estimator. It may perform the same function for study network applications such as power flow.

Background

Software tools such as the network NTP, state estimator, and contingency analysis allow RCs and TOPs to maintain current information about the condition of their bulk electric system facilities and to monitor the impacts on those facilities of events in neighboring systems.

The electricity system behaves quite dynamically during the course of a day. NTP tracks changes in system configuration using algorithms that regularly analyze phenomena such as changing breaker and switch status. The result is an accurate model of the current system configuration and preparation of data needed for other situational awareness tools. NTP configuration models are vital to downstream applications such as state estimators.

RTBPTF agrees with a recommendation made at the July, 2004 FERC Technical Conference[30] that NTP use be a minimum requirement for reliability entities. The task force also fully supports the *Outage Task Force Final Blackout Report* observation that the state estimator require a "… model of the power system that reflects the configuration of the network (i.e. which facilities are in service and which facilities are not)..."[31] This conclusion effectively mandates NTP usage.

The constant evaluation of electrical connectivity is essential to provide input to the state estimator (and other near-real-time network applications). Consequently, the NTP must be highly available and its analyses highly accurate for reliability entities to effectively monitor bulk electric system conditions. As a result of the blackout investigation findings, NERC issued directives to FE, MISO, and Pennsylvania-New Jersey-Maryland Interconnection (PJM), including a mandate that FE ensure that its state estimator and contingency analysis functions "execute reliably full contingency analyses automatically every ten

---

[30] Macedo, Frank. 2004. *Reliability Software Minimum Requirements & Best Practices*. FERC Technical Conference, July 14.

[31] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April. p. 47.

minutes or on demand, etc." NERC also required MISO to fully implement and test its NTP to provide operating personnel a real-time view of system status for "all transmission lines operating and all generating units within its system, and all critical transmission lines and generating units in neighboring systems." Entities were also required "to establish a means of exchanging outage information" within their footprints and with neighboring systems to ensure that each state estimator "has accurate and timely information to perform as designed."[32]

The purpose of the NTP section of the Real-Time Tools Survey was to obtain a snapshot of current NTP usage throughout the industry. Special emphasis was placed on determining reliability entities' practices for viewing and monitoring bulk electric system elements as well as maintenance and support practices related to NTP. Results summarized below emphasize responses from RCs and TOPs because limited response was received from BAs.

See Section 2.4, Topology and Analog Error Detection, for a discussion of enhanced topology error detection.

Summary of Findings

Key survey results from the NTP section are that NTPs are operational at many RCs and TOPs, required to develop topology models for the state estimator and contingency analysis applications, used to independently detect isolated and/or disconnected equipment, used to support other situational awareness tools (i.e., dynamic mapboards), executed frequently and quickly, and monitored to ensure high availability.

RTBPTF recommends additions to/modifications of certain NERC reliability standards to ensure NTP availability, performance, and accuracy. The task force recommends that compliance measures be appropriately coordinated with the alarm tools and/or state estimator applications.

Survey results suggest that NTP is commonly used throughout the industry, primarily by system operators and control room personnel. The survey found that NTP algorithms execute rapidly and on a regular or frequent basis.

Considering these findings and the necessity for developing accurate connectivity models reflecting real-time system conditions, the task force classifies NTP as a critical real-time tool.[33]

A significant number of RCs and TOPs responded to the survey questions regarding NTP, and responses from these two groups were fairly consistent.

---

[32] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April. p. 152.
[33] The concept of a "critical real-time tool" is explained in Section 5.4, Critical Applications Monitoring.

Other groups responded in statistically insignificant numbers; therefore, most of the discussion in this section is limited to RC and TOP responses.

Characteristics of Network Topology Processors

The survey results confirm that NTPs are widely used and operational throughout the industry, as shown in Table 2.3-1. Ninety-four percent of RCs (16 out of 17) and 67 percent of TOPs (18 out of 27) who responded to the survey report that they have NTPs. In addition, almost all RCs (16 out of 16) and TOPs (17 out of 18) that have this application indicate that it is operational. Two TOPs plan to add NTPs in the future, and 1 RC and 7 TOPs do not plan to add NTPs.

NOTE: In the columns of all tables in this section that list percentages of respondents, the percentage value is preceded by the number of respondents out of the total that gave the indicated response. For example, "32/38=84%" means that 32 out of a total of 38 respondents, or 84% of respondents, gave the indicated response.

NTP Characteristics	All	RCs
Do you have Network Topology Processor?	35/47=74%	16/17=94%
Is your NTP operational?	34/35=97%	16/16=100%
Is your NTP Off-the-Shelf with some Customization?	11/34=32%	7/16=44%
Is your NTP Off-the-Shelf?	17/34=50%	6/16=38%
Is your NTP Supplied By SCADA/EMS Vendor?	30/34=88%	14/16=88%
Is your NTP Fully Integrated With Production SCADA/EMS?	32/34=94%	14/16=88%

Table 2.3-1 — NTP Characteristics

Users overwhelmingly employ "off-the-shelf" or "off-the-shelf with some customization" NTP packages (81 percent of RCs, 13 out of 16, and 88 percent of TOPs, 15 out of 17), which suggests that vendor packages with satisfactory NTP functionality are available. NTP packages are typically fully integrated with users' EMS systems. However, some respondents use third-party or in-house products. One RC's NTP is interfaced to the SCADA/EMS, and another RC's NTP is a stand-alone product. Nearly 90 percent of RCs' (14 out of 16) and TOPs' (15 out of 17) NTPs were provided by their SCADA/EMS vendors. Two RCs and no TOPs obtained their NTPs from a third-party vendor. Two TOPs and no RCs developed their NTPs in house.

Respondents with functioning NTP applications report overwhelmingly [94 percent of RCs (15 out of 16) and 94 percent of TOPs (15 out of 16)] that their NTPs use a topology algorithm rather than a Boolean or other type of approach. Most of the 33 RCs and TOPs responding to the NTP questions report that their NTPs are interfaced for use by the state estimator and power-flow applications. High percentages (about two-thirds or more) of both RCs and TOPs interface their NTPs to SCADA and contingency analysis applications. Other functions are also interfaced but to a lesser degree. See Table 2.3-2. Several entities took the time to comment that their NTPs are also interfaced to an outage-scheduling system, which suggests that this interface, not specifically itemized in the survey question, may be relatively common as well.

NTP Application Interfaces	All	RCs
SCADA	26/34=76%	11/16=69%
Alarm Tools	14/34=41%	8/16=50%
Monitoring and Visualization Tools	16/34=47%	10/16=63%
Topology Error Detection	15/34=44%	10/16=63%
State Estimator	32/34=94%	16/16=100%
Contingency Analysis	26/34=76%	14/16=88%
Critical Facility Loading Assessment	4/34=12%	2/16=13%
Power Flow	29/34=85%	14/16=88%
Study Real-Time Maintenance	10/34=29%	6/16=38%
Other(s)	3/34=9%	2/16=13%

Table 2.3-2 — NTP Application Interfaces

Seventy-nine percent of respondents (12 RCs and 14 TOPs) report that they need to manually update non-telemetered internal facility status points. This suggests that even though a majority of respondents interface their SCADA systems with the NTP, many must manually maintain status information in some locations to support all equipment in their models. At least two-thirds of RCs (12 out of 16) and TOPs (11 out of 17) indicate that they must perform manual updates of external facility status points. If these status points are not kept current, their "wide-area view"[34] of the bulk power system could be affected.

NTP Users

The majority of respondents, i.e., 94 percent of RCs (15 out of 16) and 82 percent of TOPs (14 out of 17), indicate that operators and other control room staff are the primary users of NTP, suggesting that the application is primarily a situational awareness tool for operators. Although others use it, the percentages are much smaller, as Table 2.3-3 shows.

[34] "Wide-area view" is a term introduced by Standard IRO-003.

Users	Who are primary Users?		Who are secondary Users?	
	All	RCs	All	RCs
System Operators and/or Other Control Room Staff	30/34=88%	15/16=94%	3/29=10%	1/15=7%
Operations Support Staff	16/34=47%	8/16=50%	13/29=45%	7/15=47%
EMS and/or information technology (IT) Support Staff	9/34=26%	4/16=25%	16/29=55%	7/15=47%
Supervisory and/or Management Staff	5/34=15%	1/16=6%	8/29=28%	3/15=20%
Other(s)	0/34=0%	0/16=0%	4/29=14%	3/15=20%
Not Used On a Continuous Basis (7 x 24 x 365)	0/34=0%	0/16=0%	1/29=3%	0/15=0%

Table 2.3-3 — Who uses NTP?

Features and Functions

All 33 RCs and TOPs rank NTP as "essential" or "desirable," which makes clear the importance of this application. The survey responses shown in Table 2.3-4, as well as the respondents' comments cited at the end of this paragraph, illustrate the variety of roles that this application plays.

NTP Functions and Features	All	RCs
Identify electrical islands & equipment in each island	31/34=91%	15/16=94%
Island detection is Essential	15/29=52%	8/14=57%
Island detection is Desirable	13/29=45%	5/14=36%
Identify equipment that is open-ended at one terminal	29/32=91%	14/15=93%
Open-ended equipment detection is Essential	14/27=52%	8/12=67%
Open-ended equipment detection is Desirable	12/27=44%	4/12=33%
Identify equipment that is completely de-energized	27/31=87%	12/14=86%
De-energized equipment detection is Essential	12/26=46%	7/12=58%
De-energized equipment detection is Desirable	12/26=46%	4/12=33%
Individually override any status in NTP, including taps	27/31=87%	13/14=93%
Override of individual status points is Essential	23/27=85%	12/13=92%
Override of individual status points is Desirable	4/27=15%	1/13=8%
Override a large number of statuses from saved case	8/31=26%	6/14=43%
Override of status pts. from saved case is Essential	3/5=60%	3/5=60%
Override of status pts. from saved case is Desirable	2/5=40%	2/5=40%
Detect and identify abnormal split buses	13/30=43%	6/14=43%
Abnormal split bus detection is Essential	6/13=46%	3/6=50%
Abnormal split bus detection is Desirable	7/13=54%	3/6=50%
Detect & identify abnormal breaker & switch statuses	25/30=83%	10/14=71%
Abnormal breaker/switch status detection is Essential	13/20=65%	3/ 7=43%
Abnormal breaker/switch status detection is Desirable	6/20=30%	4/ 7=57%
Define different voltage limits at each node	13/30=43%	8/14=57%
Different voltage limits at each node is Essential	8/12=67%	4/ 7=57%
Different voltage limits at each node is Desirable	4/12=33%	3/ 7=43%
Chronologically view all facility outages & returns	16/30=53%	9/14=64%
Chronological view of outages/returns is Essential	13/15=87%	9/9=100%
Chronological view of outages/returns is Desirable	2/15=13%	0/9=0%

Table 2.3-4 — NTP Functions and Features

NTP's roles include: preparing models for the state estimator/contingency analysis, identifying equipment outages, identifying de-energized equipment, identifying the existence of multiple network islands, and driving dynamic mapboards.[35] The number of respondents that have the features discussed in this paragraph suggests that these features are common and readily available.

[35] See Section 2.2, Visualization Tools, for a discussion of the application and prevalence of dynamic mapboards.

Most respondents [94 percent of RCs (15 out of 16) and 88 percent of TOPs (15 out of 17)] indicate that their NTPs can detect two or more electrical islands, and 93 percent of RCs (13 out of 14) and all TOPs (14 out of 14) rank this feature as "essential" or "desirable." About one-half of RCs (8 out of 14) and TOPs (6 out of 14) can specify the minimum number of buses in a valid electrical island. Respondents can identify up to a minimum of 10 electrical islands; the maximum number of islands that can be identified is essentially unbounded (9,999). One RC and 2 TOPs that do not have the island detection function indicate that it would be "desirable." Detection of open-ended or de-energized equipment is also a common feature. Very high percentages of respondents [93 percent of RCs (14 out of 15) and 88 percent of TOPs (14 out of 16)] report that their NTP applications can detect open-ended equipment at one terminal, and 86 percent of RCs (12 out of 14) and 88 percent of TOPs (14 out of 16) can detect de-energized equipment. Users overwhelmingly (more than 90 percent) rate these features as "essential" or "desirable."

The respondent's comments below suggest the importance and variety of NTP implementations:

> "There is topology processing that is integrated into the State Estimator and the other network applications. We also have a SCADA topology processor that runs as part of the SCADA environment to indicate de-energized equipment based solely on SCADA information."
>
> "Topology outputs are used for mapboard indication and line, transformer, and outage alarming."
>
> "Provides bus/branch model for State Estimator and other network applications. Provides current and chronological history of facility status. Detects network islanding."
>
> "Local and wide area situation awareness would be very difficult to achieve, if at all, without network topology. One could not, generally speaking, achieve good contingency analysis results without NTP."

Additional survey questions reveal other, less common uses of NTP. For example, 43 percent of RCs (6 out of 14) and 40 percent of TOPs (6 out of 15) use NTP to detect abnormal split buses. All of the RCs (6 out of 6) and TOPs (6 out of 6) that have abnormal split bus detection rank this feature "desirable" or "essential," with RCs rating the function as essential more frequently than TOPs. Seventy-one percent of RCs (10 out of 14) and 93 percent of TOPs (14 out of 15) can also detect abnormal breaker and switch status. However, this feature is not used by all who have it. Most RCs (7 out of 7) and TOPs (11 out of 12) that have and use this feature consider it "essential" or "desirable." In contrast to many other NTP-related features and functions, TOPs (9 out of 12) rank this feature "essential" more often than did RCs (3 out of 7), suggesting that TOPs that have the feature consider it to be important. It should be noted that every one of the RCs (4 out of 4) that reported that they did not have the feature indicate that it would be “desirable.”

Performance, Monitoring, and Availability

Several survey questions attempted to quantify NTP performance, which could be useful information for establishing norms. The results indicate that the NTP function requires minimal execution time and is generally set to run automatically and fairly frequently. When asked how their NTP is normally triggered to run in real time, all RCs (16 out of 16) and all TOPs (17 out of 17) report that their NTPs were triggered to run automatically.

Users report a fairly wide range of cycle times - from a low of two seconds to a high of 1,800 seconds - with an average of just under 300 seconds (five minutes). For most, the function executes rapidly. The 16 RCs and 17 TOPs report times averaging well under 10 seconds, and many respondents (11 out of 16 RCs and 12 out of 17 TOPs) report times of five seconds or less. Seven RCs and TOPs require as little as one second to execute the application, and no one reports an execution time that exceeds 30 seconds.

In addition to addressing execution speed and frequency, the survey addressed availability and monitoring. This information is of interest to the task force for establishing reasonable recommendations for standards and compliance measures. Companies were asked to report multiple monitoring tools if applicable. Eighty percent of RCs (8 out of 10) and 80 percent of TOPs (8 out of 10) report that the most common method of monitoring NTP availability is a “watchdog.” Other techniques include 1 RC using a redundant system comparison and 5 RCs and TOPs using alarm displays, flag and system messages, operator monitoring, and system health checks to ensure availability. Of those reporting, 7 out of 10 RCs and 6 out of 10 TOPs indicate that alarm tools show NTP status to support personnel; 50 percent of RCs (5 out of10) use continuous displays for this purpose. Paging systems, web-based or special application displays, and email and phone calls are also employed but by less than 50 percent of any reporting group. Two-thirds of the RCs and TOPs responding (12 out of 18) indicate that failed status is detected and reported within 300 seconds or less. Responses from 10 RCs and 8 TOPs indicate that failed status is detected and reported in time frames ranging from a minimum of one second to a maximum of 1,560 seconds (26 minutes).

Frequency of Regular Manual Health Checks for the Entity's NTP	All	RCs
Weekly	1/21=5%	0/12=0%
Daily	4/21=19%	3/12=25%
Hourly	1/21=5%	1/12=8%
As Needed	12/21=57%	5/12=42%
Other(s)	3/21=14%	3/12=25%

Table 2.3-5 — NTP Manual Health Checks

Table 2.3-5 summarizes the responses regarding how often a regular manual NTP health check is performed. Twenty-one respondents answered this survey question. Overall, 42 percent (5 out of 12) of RCs and 57 percent (12 out of 21) TOPs that responded to this survey question report that regular, manual health checks are performed on an as-needed basis to ensure that the NTP application is running successfully. The remaining respondents report that their NTP health checks are performed continuously with different periodicities as indicated in the table.

NTP Monitor and Metrics	All	RCs
Does your NTP have the ability to detect and independently notify operators and support staff that the NTP is down or functioning incorrectly?	20/30=67%	10/14=71%
Do you use a Watchdog to detect NTP failures?	16/20=80%	8/10=80%
Is the status of NTP monitored continuously (24x7x365)?	21/21=100%	12/12=100%
Do operators attempt to resolve problems prior to notifying support?	8/21=38%	5/12=42%
Are your support personnel available continuously (24x7x365)?	18/21=86%	11/12=92%
Do you have historical NTP solution rate data and/or metrics?	8/31=26%	6/15=40%

Table 2.3-6 — NTP Monitor and Metrics

Overall, only 26 percent of respondents (6 out of 15 RCs and 2 out of 15 TOPs) have solution availability metrics to describe how often NTP solves for a given number of runs (see Table 2.3-6). Although this is a statistically small group, 100 percent of those that have metrics (6 out of 6 RCs and 2 out of 2 TOPs) use them, and most (5 out of 6 RCs and 2 out of 2 TOPs) rate them "desirable" or "essential" for situational awareness. Sixty percent of respondents without metrics (including 7 out of 9 RCs and 7 of 13 TOPs) indicate that metrics would have minimal value. Two-thirds of RCs (4 out of 6) and half of the TOPs (1 out of 2) with metrics generate their statistics automatically. No respondents generate them manually. However, 1 respondent's metrics are based on the number of solutions obtained while another respondent runs scripts each day to derive the metrics.

See the "Support" subsection below for further discussion.

Questions regarding the periodicity of metrics and the period of unavailability that respondents consider will have significant impact on their system operations elicited only a small number of responses (6 total). Therefore, RTBPTF can draw no conclusions on these issues. It is of interest that availability statistics appear to be based on estimated rather than calculated values. In addition, although only a limited number of respondents address the leading causes of NTP unavailability, the two causes cited are bad telemetry (with good quality codes) and data link/lost telemetry (at least 1 respondent reports that more than 50 percent of problems resulted from these two causes).

Enhanced Functionality

Of those responding to questions about NTP enhanced functionality, most RCs (13 out of 14) and TOPs (13 out of 16) can override individual status telemetry, including tap positions. All respondents that have this feature rate it “essential” or “desirable” (13 out of 13 RCs and 13 out of 13 TOPs). Some RCs (6 out of 14) and TOPs (2 out of 16) can also override status telemetry, in bulk, from saved cases. This feature, which is useful in the event of an ICCP (or similar) data-link loss, appears to be more highly valued by RCs than TOPs; all 5 RCs but none of the TOPs rank this feature “essential” or “desirable.”

Fifty-seven percent of RC respondents (8 out of 14) and 27 percent of TOPs (4 out of 15) can define different voltage limits at each node and use the most restrictive limit for each resultant bus. Although 100 percent of those using this feature (7 out of 7 RCs and 4 out of 4 TOPs) consider it “essential” or “desirable,” fewer than one-third of the RCs and TOPs who do not have this feature rank it “desirable” (5 out of 17). There may be some confusion about the purpose and/or application of nodal voltage limits given the importance placed on them by those who use this feature in contrast to those who do not (and do not believe they need it).

Sixty-four percent of RCs respondents (9 out of 14) and 40 percent of TOPs (6 out of 15) can view chronologically all facility outages and returns. Almost all RCs (9 out of 9) and TOPs (5 out of 6) that have this feature use it. Of those using it, RCs unanimously (9 out of 9) rank it “essential,” and all TOPs (5 out of 5) rank it “essential” or “desirable.” Of those that do not have the feature, 80 percent of RCs (4 out of 5) and 55 percent of TOPs (5 out of 9) indicate that the feature would be “desirable.”

Support

The essential nature of network topology processing is evidenced by the number of respondents that have tools to monitor the status of this function and alert support staff to problems. As previously noted (Table 2.3-6), of those responding, 71 percent of RCs (10 out of 14) and 67 percent of TOPs (10 out of

15) can detect and independently notify operators and support staff that the NTP is down or functioning incorrectly. All 10 RCs and 10 TOPs with this feature consider it "essential" or "desirable," and 50 percent of RCs (2 out of 4) and 100 percent of TOPs (5 out of 5) that do not have the feature state that it would be "desirable."

A variety of support groups may get involved when NTP problems arise. The "System Operators and/or Other Control Room Staff" group is most commonly notified when NTP fails; 80 percent (8 of 10) of RCs and 60 percent of TOPs (6 of 10) notify this group. Operations support staff are often notified when NTP fails at RCs (7 of 10) but not at TOPs (only 1 of 10). The responses were more balanced for notification of EMS and/or information technology (IT) Support Staff; 5 of 10 RCs and 6 of 10 TOPs report using this strategy. Smaller numbers of respondents notify supervisory personnel or "Others." One company stated that "24/7 and on-site support staff are paged." See Table 2.3-7.

What Personnel are Notified of NTP Failures?	All	RCs
System Operators and/or Other Control Room Staff	14/20=70%	8/10=80%
Operations Support Staff	8/20=40%	7/10=70%
EMS and/or IT Support Staff	11/20=55%	5/10=50%
Supervisory and/or Management Staff	2/20=10%	2/10=20%
Other(s)	1/20=5%	1/10=10%

Table 2.3-7 — What Personnel are Notified of NTP Failures?

About 70 percent of those responding, including 80 percent of RCs (12 out of 15) and 57 percent of TOPs (8 out of 14), have tools to monitor NTP status and alert support personnel to problems. See Table 2.3-7. All RCs (12 out of 12) and TOPs (8 out of 8) that have this feature consider it "essential" or "desirable." Of those that do not have NTP Status Monitoring and Support Personnel Notification, 2 out of 3 RCs and 3 out of 6 TOPs rate this feature "desirable." All respondents that have the feature (12 RCs and 8 TOPs) monitor NTP support status 24x7x365. Roughly 40 percent of RCs (5 out of 12) and 38 percent of TOPs (3 out of 8) indicate that operators attempt to resolve problems prior to notifying support staff. Of those using NTP monitors, 92 percent of RCs (11 out of 12) and 75 percent of TOPs (6 out of 8) have support staff available continuously (24x7x365).

The survey responses indicate that support personnel notification procedures are well established and formalized, which suggests the importance respondents place on maintaining NTP's operational status. RCs and TOPs rely on multiple notification methods. Overall, two-thirds of those reporting, including 83 percent of RCs (10 out of 12) and 50 percent of TOPs (4 out of 8), indicate that the most common notification method is that operators process alarms and call support personnel as needed. The next-most-common method, used by about 50 percent overall, is to have support personnel on call, ready to connect remotely after business hours to fix problems as necessary [50 percent of RCs (6 out of 12), and 63 percent of TOPS (5 out of 8)]. Approximately 43 percent overall, with 42 percent of RCs (5 out of 12) and 50 percent of TOPs (4 out of 8) have support personnel on call who can report on site after business hours to fix reported problems. About one-third overall, including 4 out of 12 RCs and 3 out of 8 TOPs, rely on automatic paging systems activated by the application to notify support personnel of problems. Overall 33 percent, including 42 percent of RCs (5 out of 12) and 13 percent of TOPs (1 out of 8), have support staff on duty, monitoring applications continuously. One company resolves problems the next business day.

The majority of RCs and TOPs have de-bugging tools. See Table 2.3-8. Overall, program error logs and displays (13 out of 17) and program source codes (12 out of 17) are the most commonly used de-bugging tools. Embedded parameters/flags and code debugging software are used to a lesser extent. All RCs (11 out of 11) and 50 percent of TOPs (3 out of 6) with de-bugging tools rank them “desirable” or “essential,” and 100 percent of RCs (4 out of 4) and 75 percent of TOPs (6 out of 8) that have no de-bugging tools indicate that these tools would be “Desirable.” This suggests that improved de-bugging tools would be useful for NTP support. The tools currently available vary. Respondents who report having this feature tend to have multiple de-bugging tools.

What Types of De-Bugging Tools do You Have?	All	RCs
Do you have debugging tools for NTP?	18/31=58%	11/15=73%
Embedded debug parameters/flags that could be enabled/disabled	7/17=41%	5/11=45%
Program Error Logs and Displays	13/17=76%	8/11=73%
Program Source Code	12/17=71%	7/11=64%
Code Debugging Software	7/17=41%	5/11=45%
Other(s)	2/17=12%	2/11=18%

Table 2.3-8 — Types of De-Bugging Tools

In response to questions about NTP support activities, all respondents indicated that they assign in-house staff to NTP support (12 out of 12 RCs and 8 out of 8 TOPs); a few respondents involve vendors in support activities (3 out of 12 RCs and 0 out of 8 TOPs). For almost 40 percent of all respondents, including 42 percent of RCs (5 out of 12) and 20 percent of TOPs (1 out of 5), operators and support personnel use written procedures to fix NTP problems; about 67 percent of the RCs (8 out of 12) and 40 percent of TOPs (2 out of 5) use vendor documentation for this purpose. Some respondents state that customized displays, on-the-job experience, and specialized training are required for personnel to be proficient at diagnosing problems and de-bugging the application. Some respondents also perform regular manual NTP health checks using a combination of written procedures (6 out of 10 RCs and 0 out of 6 TOPs) and vendor documentation (2 out of 10 RCs and 3 out of 6 TOPs). In some cases, customized on-line displays assist with failure detection and de-bugging;

one company performs health checks when they notice discrepancies between map board and SCADA systems. No one uses interactive help guides for these purposes. See Section 2.4, Topology and Analog Error Detection, for a discussion of survey results regarding software tools that address metering/status inconsistencies, etc.

Recommendations for New Reliability Standards

RTBPTF considers NTP a mandatory tool for ensuring bulk electric system situational awareness. RTBPTF believes that NTP is of equal importance to the other mandatory tools such as the state estimator and contingency analysis, especially when used to drive alarming and visualization tools. Accordingly, RTBPTF recommends modifications to existing standards to clarify that use of NTP is mandatory (see the Reliability Toolbox Rationale and Recommendation section). In the following discussions, RTBPTF supports the major recommendation to make NTP mandatory.

The results of the RTBPTF survey detailed above support the assertion of Macedo (2004)[36] that a NTP is a minimum requirement — i.e., an essential tool for operators. NTP availability and recommendations are discussed in detail in the following subsections below.

Recommendation – S1

Mandate the following reliability tools as mandatory monitoring and analysis tools

- Alarm Tools
- Telemetry Data Systems
- Network Topology Processor
- State Estimator
- Contingency Analysis

Network Topology Processor: Mandatory Monitoring and Analysis Tool

Survey results indicate that NTPs are delivered as a standard part of commercially available, modern SCADA/EMS systems. Existing NERC reliability standards require the use of "adequate analysis tools" to aid operators in maintaining situational awareness for the bulk electricity system. Standard IRO-002 (Requirement R7) states "[e]ach Reliability Coordinator shall have ***adequate analysis tools*** [emphasis added] such as state estimation, pre and post-contingency analysis capabilities (thermal, stability, and voltage), and wide area overview displays." Specifying the NTP as part of the Reliability Toolbox[37] eliminates the vagueness in the current NERC reliability standards regarding

[36] Macedo, Frank. 2004. *Reliability Software: Minimum requirements and Best practices*. FERC Technical Conference. July 14. http://www.ferc.gov/EventCalendar/Files/20040716092511-20040714085315-FrankMacedo.pps

[37] The Introduction to this report discusses the inclusion of the Network Topology Processor as part of the Reliability Toolbox.

whether NTP, as defined, is mandatory. The recommendation also provides clarity to the term “adequate analysis tools.”

Recommendation – S8

Specify and measure minimum availability for network topology processor

Network Topology Processor Availability

The two main uses of the NTP are:

- To develop electric connectivity models as input to the state estimator, contingency analysis, or other analysis tools
- To generate operator displays for alarming and visualization (i.e., mapboards) of the status of elements of the bulk electric system (i.e., whether they are energized, open ended, or de-energized) as well as when electrical islands exist

For the first type of use, if an entity is using NTP only as an input to the state estimator, contingency analysis, or other analysis tools, the availability requirements for the state estimator[38] and contingency analysis[39] are sufficient to ensure that the entity’s NTP is available. That is, if the entity’s state estimator and contingency analysis are compliant per their respective availability standards, having a separate availability metric for NTP availability is unnecessary and redundant.

For the second type of use, RTBPTF recommends that reliability entities monitor the performance of their NTPs and measure availability because, for this use, the operators depend on NTP for situational awareness.

RTBPTF Recommendation

RTBPTF recommends that all RCs and TOPs be required to monitor the performance of their NTPs and measure availability when NTPs are used to generate operator displays for alarming and visualization (i.e., dynamic mapboards) of the status of elements of the bulk electric system (i.e., whether they are energized, open ended, or de-energized) as well as when electrical islands exist. RTBPTF believes that when NTP is used in this fashion, it needs to run more often and to be available.

[38] The availability requirement for state estimator is discussed in detail Section 2.5.
[39] The availability requirement for contingency analysis is discussed in detail Section 2.6.

This recommendation shall only apply to entities that have stand-alone NTPs (i.e., a totally separate application that develops the electric connectivity models)[40] that drive alarm tools and visualization tools. RTBPTF recommends that a new requirement be established under the current Standard TOP-006 (Monitoring System Conditions) that shall apply to both RCs and TOPs and require NTP availability:

> PR1. Network Topology Processor (NTP) Availability. Each Reliability Coordinator and Transmission Operator shall operate its NTP such that its NTP shall have at least one test topology change (or "watchdog" event) generated and processed at least every Telemetry Data System scan rate. This test event (or "watchdog" event) could originate from a test field device or could be application generated.

Although the NERC Standards process might address other factors in considering this recommendation, RTBPTF recommends the following measure for the requirement stated above:

> PM2. Each Reliability Coordinator and Transmission Operator shall maintain NTP application logs, reports, or documents demonstrating that the Responsible Entity's NTP processed the test topology change (or "watchdog" event) according to Requirement PR1.

Rationale

The electricity system behaves quite dynamically during the course of a day. NTP could be used to track changes in system configuration using algorithms that regularly analyze phenomena such as changing breaker and switch status in real time. The result is an accurate model of the current system configuration and preparation of data needed for other situational awareness tools. Used in this fashion, an available and robust NTP is essential to operators for timely detection of network topology changes. A metric to measure NTP availability provides a standardized method to measure performance.

Current Network Topology Determination

Standard IRO-005 (Requirement R1.1) states that each reliability coordinator shall monitor its reliability coordinator area parameters, including "[c]urrent status of Bulk Electric System elements (transmission or generation including critical auxiliaries such as Automatic Voltage Regulators and Special Protection

[40] Some entities have a state estimator that has integrated the NTP functions and is not used for the purpose of alarming and visualization. Only stand-alone NTPs that drive alarm and visualization tools would have a required availability metric.

Systems) and system loading." RTBPTF recommends that Standard IRO-005 (Requirement R1.1) be modified to include a requirement that status information associated with transmission and generation elements be processed to determine current network topology. As a measure, topology results should be displayed to operators through alarms and visualization tools to indicate when equipment is disconnected, de-energized, or electrically isolated.

RTBPTF Recommendation

Standard IRO -005 (Requirement R1.1) should be modified as follows:

R1.1. Current status of Bulk Electric System elements (transmission or generation including critical auxiliaries such as Automatic Voltage Regulators and Special Protection Systems) and system loading. In addition, status information associated with transmission and generation Bulk Electric System and wide-area network elements shall be processed to determine current network topology. Results of the topology analysis shall be used to make operators aware of electrical islands and disconnected or de-energized equipment immediately after they are detected.

RTBPTF recommends the following measures for the modified requirement stated above:

PM1.1. Demonstrate that status change(s) are processed by NTP (or equivalent application[41]) to provide accurate configuration data before and after the change(s). Demonstrate that de-energized or disconnected equipment and formation of electrical islands are immediately displayed to operators via visualization tools.

Rationale

The task force survey results and comments make clear that NTP is an important, commonly used operator tool. NTP's primary functions include analyzing and establishing network topology and detecting electrical islands and disconnected or de-energized equipment. The *Outage Task Force Final Blackout Report* implies NTP's critical nature and importance for dynamically determining connectivity.

Several survey respondents' comments reinforce the importance of NTP. One respondent states that "local and wide area situation awareness would be very difficult to achieve, if at all, without network topology.

[41] Entities may used their Telemetry Data Systems (e.g., SCADA topology processing through Boolean logic equations/definitions) to provide topology detection functionality.

The task force recognizes that NTP functionality is multi-dimensional and that NTP is required to maintain the reliability of the bulk electric system. Topology analysis enhances operator situational awareness. Several survey respondents use NTP output independently of the network connectivity/topology to drive dynamic mapboards or other display devices that can serve as “outage display boards,” as the sample quotes below indicate:

> “There is topology processing that is integrated into the State Estimator and the other network applications. We also have a SCADA topology processor that runs as part of the SCADA environment to indicate de-energized equipment based solely on SCADA information.”
>
> “Topology outputs are used for mapboard indication and line, transformer outage alarming.”

These activities directly support recommendations in Section 7 of the *Outage Task Force Final Blackout Report,* which compares the August 14, 2003 blackout with previous disturbances. In the discussion of System Visibility Procedures and Operator Tools, the report cites the following recommendation (among others) from previous investigations:

> In the control center, use a dynamic line loading and outage display board to provide operating personnel with rapid and comprehensive information about the facilities available and the operating condition of each facility in service.[42]

The task force agrees and recommends that standards be modified to support activities that drive outage display boards or other devices and tools and provide operating personnel with ”rapid and comprehensive information about the facilities available.”

Applicability Statement for Recommended Standards

RTBPTF recommends that all RCs and TOPs be required to have NTP for monitoring the status of bulk electric system equipment to analyze electrical connectivity in near real time and prepare electrical models for further analysis by the state estimator, contingency analysis, etc. as defined in the recommended additions or modifications to the NERC Standards applicable to RCs and TOPs. Other responsible entities that use network topology processors to support or complement their RCs’ ability to operate the bulk electric system reliably in accordance with formal agreements, contracts, or established practices or procedures shall be subject to the same standards for NTPs as their RCs.

---

[42] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April. p.108.

Recommendation – G3

Develop a chronological outage/return summary in network topology processor for recreating events and aiding state estimator.

Recommendations for New Operating Guidelines

In Section 2.9, Study Real-Time Maintenance, RTBPTF recommends the development of operating guidelines for study real-time maintenance applications. This capability is useful for maintaining highly available, accurate network analysis tools and supports the *Outage Task Force Final Blackout Report* Recommendation 37: "Improve IT forensic and diagnostic capabilities." The applications cited by RTBPTF as important to "improve IT forensic and diagnostic capabilities" should include NTP. About 50 percent (16 out of 30) of all survey respondents can view, chronologically, all facility outages and returns. Of the respondents that do not have this feature, 64 percent (9 out of 14) reported that it would be "desirable." RCs favored this feature more strongly than TOPs (100 percent of RCs rated it "essential.") A chronological outage/return summary is useful for recreating events and aiding state estimator troubleshooting. RTBPTF recommends that an Operating Guideline be developed for this NTP function.

Areas Requiring More Analysis

RTBPTF did not identify any Areas Requiring More Analysis related to NTP.

Examples of Excellence

The RTBPTF did not identify any Examples of Excellence related to NTP.

Section 2.4
Topology and Analog Error Detection

Definition

Topology and analog error detection (TAED) utilizes a computer application to identify and/or automatically override incorrect SCADA information regarding the statuses of breakers and switches. TAED is used to support NTP and improve the accuracy and robustness of the state estimator application. TAED also may identify and/or automatically ignore analog SCADA measurements that are unreasonable or inconsistent with network connectivity. Topology and analog error detection can serve as a pre-processor to other applications and can debug problems in the solutions those other applications produce. TAED can evaluate data, removing inconsistencies that may occur, for example, when direct information on equipment status indicates an open circuit while analog data suggests that power is flowing.

Background

This section of the report was developed to assess applications designed to eliminate or override incorrect or unreasonable status and/or analog data before NTP and the state estimator are executed. This pre-processing could enhance NTP and improve the quality of SE solutions.

TAED tools have great potential as pre-processors and debuggers for improving the performance of state estimator and other real-time tools. Although the industry would benefit from their universal use, their use currently is limited, perhaps because they are less effective than they need to be. TAED tools require redundant measurements in order to evaluate situations, identify inconsistent data, and provide accurate results. Developers of these tools should be encouraged to work with users to determine the model accuracy and measurement redundancy needed for the tools to perform well.

Because TAED is not used widely, RTBPTF does not consider this a critical reliability tool for operators and thus does not recommend creating or modifying reliability standards or operating guidelines to include TAED. RTBPTF does, however, recommend that TAED be analyzed further because this tool has potential to enhance NTPs and improve the quality of state estimator solutions.

Summary of Findings

Although TAED tools are available, the small number of survey responses makes it difficult to draw conclusions about industry-wide trends.

Survey responses and comments suggest that TAED tools are not generally used successfully, at least in part because there may be insufficient redundancy in the measurements available for analysis.

One respondent notes that "Topology Error Detection is used with our State Estimator. It has not proven very useful at this time. It works fairly well in well-measured parts of the system, but these were easy to detect before."

Section 2.3, Network Topology Processor, discusses in detail topics such as developing bus-branch models and detecting open equipment. In addition, some aspects of TAED are almost universally integrated into state estimator processes, as described in Section 2.5, State Estimator.

Prevalence and Perceived Value

Overall, 45 percent of those who responded to the TAED section of the Real-Time Tools Survey (21 out of 47) report having applications that provide TAED. This compares with 74 percent of respondents who reported having NTPs. RCs tend to use TAED more than do TOPs. Sixty-five percent of RCs (11 out of 17) report having operational TAED applications whereas just 27 percent of TOPs (7 out of 26) have operational TAED applications (1 TOP reports having a non-operational application). Two RCs and 4 TOPs indicate that they plan to acquire TAED.

The 9 respondents who submitted written comments on TAED convey a range of opinions about the application, as illustrated by the following quotations.

> "This feature allows RC1 to be aware of the telemetry which is not accurate. This improves situational awareness in monitoring the electrical power grid."
>
> "We've experienced some occurrences and it is useful but the occurrences are rare."
>
> "Topology Error Detection is used with our State Estimator. It has not proven very useful at this time. It works fairly well in well measured parts of the system, but these errors were easy to detect before."
>
> "Very essential."
>
> "On our system this is part of the state estimator preprocessing. It is not a stand alone application. Analogs and statuses that are inconsistent are identified in the application logs."
>
> "We don't have Topology Error Detection."
>
> "The use of a topology and analog error detection algorithm is one of the most important tools of our advance tools. It provides us the information to correct any measurement and false switch states. We can then send the right topology to our state estimator."

"Debugging solution problems without analog error detection would be very difficult, if not impossible in a r/t time line."

"Topology error detection is a separate function from analog error detection. Only analog error detection is functional at this time."

Availability and Interface with Other Applications

Survey results suggest that users can easily purchase TAED applications. Ten out of 11 RCs and all 7 TOPs that have operational applications report that their TAED software is "off-the-shelf" or "off-the-shelf with some customization." No one reports using applications that are highly customized or developed in house. As might be expected, the RCs and TOPs that have software supplied by their EMS vendors note that it is fully integrated with SCADA/EMS. Of 2 RCs who report having third-party products, one indicates that the package is fully interfaced with EMS, and the other reports using a stand-alone TAED.

Table 2.4-1 illustrates the various applications that respondents report are interfaced with TAED.

NOTE: In the columns of all tables in this section that list percentages of respondents, the percentage value is preceded by the number of respondents out of the total that gave the indicated response. For example, "32/38=84%" means that 32 out of a total of 38 respondents, or 84% of respondents, gave the indicated response.

TAED Interfaces	All	Reliability Coordinators
SCADA	11/20 = 55%	4/11 = 36%
Alarm tools	6/20 = 30%	2/11 = 18%
Monitoring and visualization techniques	7/20 = 35%	6/11 = 55%
Network topology processor	11/20 = 55%	7/11 = 64%
State estimator	19/20 = 95%	11/11 = 100%
Contingency analysis	7/20 = 35%	5/11 = 45%
Critical facility loading assessment	0/20 = 0%	0/11 = 0%
Power flow	8/20 = 40%	6/11 = 55%
Study real-time maintenance	5/20 = 25%	4/11 = 36%
Other(s)	1/20 = 5%	1/11 = 9%

Table 2.4-1 — TAED Interfaces

Users

System operators and other control room staff are the primary users of TAED applications, as reported by 73 percent of RCs (8 out of 11) and 71 percent of TOPs (5 out of 7). As shown in Table 2.4-2, operations support staff and EMS and/or IT support staff are variously identified as primary or secondary users. Supervisory and management staff are very infrequently identified as users.

Users	Who are Primary Users?		Who are Secondary Users?	
	All	RCs	All	RCs
System operators and/or other control room staff	13/20 = 65%	8/11 = 73%	4/18 = 22%	2/11 = 18%
Operations support staff	9/20 = 45%	7/11 = 64%	10/18 = 56%	7/11 = 64%
EMS and/or IT support staff	10/20 = 50%	4/11 = 36%	6/18 = 33%	2/11 = 18%
Supervisory and/or management staff	0/20 = 0%	0/11 = 0%	3/18 = 17%	1/11 = 9%
Other(s)	0/20 = 0%	0/11 = 0%	2/18 = 11%	2/11 = 18%

Table 2.4-2 — Users of TAED

Features and Functions

Of those responding, 82 percent of RCs (9 out of 11) and 67 percent of TOPs (4 out of 6) state that their TAED uses a topology-based algorithm. No respondents report that their TAED uses a Boolean logic approach; 32 percent of all RCs and TOPs (5 out of 17) report "other" approaches. One respondent comments that "Analog Error Detection is part of their [state estimator] SE solution," and others comment that they use a "vendor custom algorithm" or "State Estimator error processing."

Eight out of 12 RCs and all 7 TOPs indicate that their applications can detect incorrect statuses of breakers and switches. The perceived value of this feature is unclear, given that 4 RCs and 4 TOPs report it would be "desirable" to have, and 5 RCs who use the feature rate it "essential" or "desirable." In contrast, 3 out of the 8 RCs who have the feature don't use it, and 1 TOP indicates it has only minimal value. These responses may indicate that although the concept is good, current implementations are ineffective, that the "payback" does not justify use of the feature, or that the feature simply is not used widely.

Overall, 75 percent of respondents (6 out of 8) report that their TAED application detects inconsistent analog and status measurements. Sixty percent of RCs (3 out of 5) and 100 percent of TOPs (3 out of 3) note that they define bad status as occurring when the analog measurement (flow) is inconsistent with the status measurement. Sixty percent of RCs (3 out of 5) and zero TOPs report that they also define bad status as occurring when status is unavailable but surrounding measurements are available. Only 4 respondents report having and using the capability to automatically override bad status, suggesting that this feature currently has limited perceived value.

All respondents (all 12 RCs and 7 TOPs) report that their TAED applications are capable of detecting unreasonable and inconsistent analog SCADA values based on topology. The survey provided two examples of this ability: 1) detecting a zero-voltage measurement at an energized bus, or 2) detecting and identifying analog values that are inconsistent with each other, such as when the sum of power flows at a bus is not close to zero. Almost all RCs (11 out of 12) and all 7 TOPs who have this feature report that it is operational. Those who use the feature consider it "essential" or "desirable." Table 2.4-3 summarizes the reasonableness/consistency checks that TAED applications provide.

Reasonableness/Consistency Checks	All	RCs
Voltage out of limits	15/20 = 75%	9/11 = 82%
Large flow on open-ended or de-energized branches	12/20 = 60%	6/11 = 55%
Sum of power flows at a bus is near zero	9/20 = 45%	4/11 = 36%
Taps outside of range	8/20 = 40%	4/11 = 36%
Unit output outside of limits	8/20 = 40%	5/11 = 45%
Flow exceeds rating	8/20 = 40%	5/11 = 45%
Small flow on In-Service branches	5/20 = 25%	3/11 = 27%
Sign of loads	5/20 = 25%	2/11 = 18%
Large losses on branch	4/20 = 20%	1/11 = 9%
Flow has same sign on both ends of branch	3/20 = 15%	2/11 = 18%
Received flow is greater than sent flow on branch	3/20 = 15%	1/11 = 9%
Other(s)	2/20 = 10%	1/11 = 9%

Table 2.4-3 — Reasonableness/Consistency Checks

The only checks that at least 50 percent of all RCs and TOPs use are voltage out of limit and large flow on open-ended or de-energized branches.

Of the 12 RCs whose applications can ignore unreasonable analog data in the state estimator solution based on topology, 9 report having this feature operational. Of the 7 TOPs who have this capability, 6 report that it is operational. All 9 RCs and 6 TOPs who use the capability deem it "essential" or "desirable."

Overall, 80 percent of respondents report that their TAED systems execute periodically, including 9 out of 11 RCs (62 percent) and 6 out of 7 TOPs (85 percent). Five out of 11 RCs (45 percent) and 5 out of 7 TOPs (71 percent) report executing the application manually or based on SCADA events (change of status or rate-of-change). Only 3 RCs report executing the program in response to disturbance events. Fifty percent of RCs (4 out of 8) indicate they execute TAED after a manual override of data (as does 1 TOP) and after an invalid/suspect solution (as do 2 TOPs). Other triggers, such as those based on a schedule or other mechanism, are used less frequently. Several respondents comment that the application can be executed at the discretion of staff or in response to predefined breakers and analog rates of change.

Based on responses from 9 RCs, the application executes periodically at intervals that range from 60 seconds to 30 minutes, with 8 out of 9 RCs reporting periodic execution every 5 minutes or less. TOPs estimate intervals that range from 10 seconds to 15 minutes, with 5 TOPs indicating that periodic execution occurs every 5 minutes or less. Nine RCs report speeds of execution that range from 1 to 30 seconds, with 7 of the 9 reporting speeds of 10 seconds or less. Seven TOPs report speeds of execution that range from 1 second to 3 minutes, with 4 indicating that the application runs in 10 seconds or less.

Monitoring, Availability, and Support

The survey asked about the availability of users' TAED applications, including how software problems/failures are detected and what typical responses are to problems. Only 4 RCs and 4 TOPs indicate that they can automatically detect and independently notify operators and support staff that TAED is unavailable or functioning incorrectly, so no conclusions can be drawn about industry trends in automated detection and notification. Five RCs who don't have this capability, however, say it would be "desirable," and 100 percent of those who have the capability call it "essential."

Only 5 RCs and 3 TOPS responded to the remaining survey questions concerning the monitoring and reporting of the status of TAED applications. Overall, 80 percent of these respondents, including 4 RCs and 2 TOPs, report that TAED status is monitored continuously (24 hours per day, 365 days per year). Two RCs and 2 TOPs report that operators initially attempt to resolve problems although 60 percent of the time operators are not first responders. When problems occur, most frequently system operators and/or other control room staff are notified; however, 4 RCs report that EMS or IT support staff are notified, 2 RCs indicate that operations support staff are notified. All of those reporting indicate that support staff respond to problems within 15 minutes of being notified.

Only 4 RCs and 3 TOPs responded to questions about who maintains and supports the TAED application. All those responding indicate that in-house staff maintain and support TAED. One RC indicates that vendor staff also are involved in supporting the application.

Just 3 RCs and 1 TOP report having historical metrics to record how often the TAED application solves for a given number of runs, but all respondents consider the feature "essential" or "desirable." Two respondents indicate that statistics are measured automatically. (The survey defined TAED solutions as 100 percent available if, for every periodic execution within a given time period, TAED solves.) Three RCs and 4 TOPs who don't have these metrics consider them "desirable." Responses to survey questions about the mean time of TAED unavailability, acceptable duration of unavailability, and frequency and acceptable rates of failure were not statistically relevant (only 2 RCs and 1 TOP responded).

Few responses were received to questions about documentation and procedures. Overall, 56 percent (including 2 out of 4 RCs and 2 out of 3 TOPs) report using vendor documentation to guide operators and support personnel in fixing TAED problems. Only 3 RCs and no TOPs report using written procedures. A few comment that experienced staff members are needed to respond to problems and that those in support will "do what is needed."

Nearly 75 percent of responding RCs (8 out of 11) indicate they have tools to aid in debugging their TAED application whereas only 43 percent of the TOPs (3 out of 7) report having those tools. Only 6 RCs use the tools, but all 3 TOPs use them. All RCs (6) and TOPs (3) using the tools consider them "essential" or "desirable" and, overall, 6 out of 8 respondents who do not have debugging tools consider such tools "desirable."

Based on limited survey responses, debugging tools are most often available through program error logs and displays (5 out of 6 RCs and 2 out of 3 TOPs) although sometimes they are part of the program source code (3 out of 6 RCs and 2 out of 3 TOPs). Embedded debugging parameters/flags also can produce debugging output, according to 2 out of 6 RCs and 2 out of 3 TOPs. In addition, 3 out of 6 RCs and 1 out of 3 TOPs report having code debugging software. One respondent notes that they have "software that downloads EMS data and runs comparisons to identify analog errors."

Recommendations for New Reliability Standards

RTBPTF does not recommend any new reliability standards or modifications to existing standards related to TAED.

Areas Requiring More Analysis

The task force recommends that providers of TAED tools consult with their customers who use (or try to use) these tools to identify and address barriers to successful implementation. These tools have great potential for improving the performance of the state estimator and other critical real-time tools, and the industry would benefit from their wider use.

Examples of Excellence

The RTBPTF did not identify any Examples of Excellence related to TAED.

Section 2.5
State Estimator

Definition

A state estimator is an application that performs statistical analysis using a set of imperfect, redundant, telemetered power-system data to determine the system's current condition. The system condition or state is a function of several variables: bus voltages, relative phase angles, and tap changing transformer positions. A state estimator can typically identify bad analog telemetry, estimate non-telemetered flows and voltages, and determine actual voltage and thermal violations in observable areas. The state estimator application has two main uses. It provides:

1. a base case for reliability-analysis applications
2. input to other system monitoring tools

The state estimator solution is typically used as the base case for other reliability-related applications, such as contingency analysis. In some cases, the state estimator is used primarily as the basis for information communicated to operators regarding power system status; e.g., the state estimator drives the alarm application that alerts operators to power system events.

Background

The state estimator application has two main uses. It provides:

1. a base case for reliability-analysis applications
2. input to other system monitoring tools

RCs and TOPs must have current information about the status of their bulk electric system facilities (system visibility) and must also be aware of events and changes in facility status in neighboring systems (situational awareness). System visibility and situational awareness depend on software tools such as the state estimator and contingency analysis. The subsections below address the use of the state estimator to maintain situational awareness. Other sections of this report address other situational awareness tools, including contingency analysis.

State estimator algorithms filter telemetry data to resolve inherent errors in the meters used to record the data. State estimators use real-time measurements from telemetry data systems to formulate a complex mathematical model of the power system that reflects the network configuration. The state estimator then uses real-time system data to estimate the voltage and phase angle at each bus, which in turn are used to estimate real and reactive power flow through each line and transformer. With sufficient metering redundancy, state estimator results are theoretically more accurate than measurements themselves. The state estimator's equipment voltage and loading information is used by reliability analysis tools, such as contingency and power-flow analysis, to simulate various conditions and outages so that operators can evaluate bulk electric system reliability. In some cases, the state estimator solution (rather than telemetry data systems) is the primary monitoring information and interface to alarm tools.

State estimation is typically performed for areas within each RC's footprint (the "RC area") as well as areas just beyond the boundaries of the RC area to include facilities within the RC's "wide area." Section 2.2 of this report, Visualization Techniques, discusses the issues related to the monitoring of the "wide area," which is key to each RC's awareness of the interconnected grid. Sections 4.1, Model Characteristics, and 4.2, Modeling Practices and Tools, discuss modeling issues related to the wide-area view boundary.

For TOPs, who are not also RCs, the state estimator scope is typically local and focuses on the TOP's internal area of responsibility. Wide-area view is not required of TOPs; however, their local view must extend beyond their internal footprint to some degree because of the modeling required for them to perform robust contingency analyses.

The state estimator is one of the first major reliability analysis applications that processes data from telemetry data systems (i.e., systems that process SCADA and ICCP data) and provides operators with a solution showing the current state of the power system. If the state estimator fails, the reliability analysis applications that depend on it (e.g., contingency analysis, power flow) cannot run; in other words, system visibility is lost, and the operator cannot detect potential SOL or IROL violations. This problem is more profound if the state estimator is the operator's primary monitoring tool.

The state estimator section of the Real-Time Tools Survey attempts to obtain a snapshot of current state estimator availability and usage in the industry. The survey emphasizes reliability entities' (RCs', TOPs', BAs') current use of the state estimator for viewing/monitoring bulk electric system elements. The survey also addresses state estimator maintenance and support practices. Because state estimators are highly dependent on network models, this section of the report also highlights issues related to modeling and practices, particularly the external network model. RTBPTF classifies the state estimator as a critical real-time tool[43] and recommends additions and modifications to certain NERC reliability standards to ensure state estimator availability and solution quality.

The *Outage Task Force Final Blackout Report* describes state estimator use as follows:

[43] The concept of a critical real-time tool is explained in Section 5.4, Critical Applications Monitoring.

> Transmission system operators must have visibility (condition information) over their own transmission facilities, and recognize the impact on their own systems of events and facilities in neighboring systems. To accomplish this, system state estimators use the real-time data measurements available on a subset of those facilities in a complex mathematical model of the power system that reflects the configuration of the network (which facilities are in service and which are not) and real-time system condition data to estimate voltage at each bus, and to estimate real and reactive power flow quantities on each line or through each transformer. Reliability coordinators and control areas that have them commonly run a state estimator on regular intervals or only as the need arises (i.e., upon demand). Not all control areas use state estimators.[44]

The state estimator must be available, and its solution must be accurate for reliability entities to effectively monitor bulk electric system conditions. In analyzing the causes of the 2003 blackout, the *Outage Task Force Final Blackout Report* states,

> One of MISO's primary system condition evaluation tools, its state estimator, was unable to assess system conditions for most of the period between 12:15 and 15:34 EDT [August 14, 2003], due to a combination of human error and the effect of the loss of the Dayton Power and Light Stuart-Atlanta line on other MISO lines as reflected in the state estimator's calculations. Without an effective state estimator, MISO was unable to perform contingency analyses of generation and line losses within its reliability zone. Therefore, MISO could not determine that with Eastlake 5 down, other transmission lines would overload if FE lost a major transmission line, and could not issue appropriate warnings and operational instructions.[45]

NERC played an important role in the blackout investigation, and, as a result of the investigation findings, issued directives on February 10, 2004 to FE, MISO, and PJM to complete remedial actions by June 30, 2004 correcting deficiencies identified as factors contributing to the blackout. These directives focused on the state estimator and related applications. NERC required FE to ensure that its state estimator and contingency analysis functions "execute reliably full contingency analyses automatically every ten minutes or on demand," and are

[44] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April. p. 47.
[45] Ibid, p. 46.

used to notify operators of potential first contingency violations.[46] NERC also required that MISO fully implement and test its network topology processor to provide operating personnel a real-time view of system status for "all transmission lines operating and all generating units within its system, and all critical transmission lines and generating units in neighboring systems." MISO also had "to establish a means of exchanging outage information with its members and adjacent systems such that the MISO state estimator has accurate and timely information to perform as designed." NERC further required that MISO fully implement and test its state estimator and contingency analysis tools "to ensure they can operate reliably no less than every ten minutes."[47]

These NERC directives indicate the importance of the state estimator for maintaining system reliability.

Summary of Findings

The responses to the state estimator section of the RTBPTF survey reveal varying degrees of practice and implementation related to the state estimator application. The subsections below address survey findings regarding: usage of state estimators**,** applications that depend on state estimator solutions, features of state estimators, timing and length of state estimator runs, convergence rate and availability of state estimators, accuracy of state estimator solutions, monitoring of external facilities, presentation of state estimator results, and maintenance and troubleshooting of state estimators.

State Estimator Usage & Prevalence

A large percentage of survey respondents use state estimators. Seventy-five percent (36 out of 48) of respondents, including all RC respondents (17 out of 17), have a state estimator (Table 2.5-1). Ninety-seven percent (35 out of 36) of the respondents that have a state estimator, including all of the RCs (17 out of 17), say that it is operational (Table 2.5-2).

Do You Have State Estimator?	RC	Other	Total
Yes	17	19	36
No		12	12
All	**17**	**31**	**48**

Table 2.5-1 — Respondents that have a State Estimator

Is Your State Estimator Operational?	RC	Other	Total
Yes	17	18	35
No		1	1
All	**17**	**19**	**36**

Table 2.5-2 — Respondents that have an Operational State Estimator

Seventy-five percent (9 out of 12) of respondents without a state estimator plan to add one in the future. Ninety-one percent (32 out of 35) of respondents with an operational state estimator rate it "essential" for situational awareness; 3 respondents, including 1 reliability coordinator, rated the state estimator "desirable."

Applications that Use the State Estimator Solution

The state estimator solution is a base case for contingency analysis for 94 percent (33 out of 35) of respondents and a base case for power flow for 97 percent (34 out of 35) of respondents. All RC respondents use the state estimator solution as a base case for contingency analysis and power flow. Eleven percent of respondents (4 out of 35) use the state estimator solution in locational marginal pricing applications. More than half of the 36 respondents who use state estimators use the base-case solution in offline power-flow applications. Twenty-nine percent (10 out of 35) of those who employ state estimators use the base case in their security-constrained economic dispatch application (see Table 2.5-3). Because multiple applications depend on the state estimator solution, it is essential that the state estimator be available and able to produce an accurate solution.

What Applications Use the State Estimator Solution as a Base Case?	RC	Other	Total
Contingency analysis	16	17	33
Voltage stability analysis	6	5	11
On-line/operator power flow	16	18	34
Off-line power flow	13	9	22
Study real-time maintenance	8	7	15

Security-constrained economic dispatch	7	3	10
Other(s)	2	2	4
Total	**16**	**19**	35

Table 2.5-3 — Applications that use State Estimator Solution as a Base Case

Respondents also use their state estimator solutions as input to monitoring tools. Table 2.5-4 shows the monitoring tools/applications that depend on the state estimator solution. RTBPTF believes that, as the performance of state estimators continues to improve, use of the state estimator solution in monitoring tools will increase. Table 2-5.4 shows the number of respondents whose state estimators interface with monitoring tools (i.e., driving the alarm tools application) Table 2.5-5 summarizes the usage of state estimators as monitoring tools. Most respondents use their state estimators to monitor MVA/Ampere loadings and low and high bus voltages.

Total	**15**	**19**	**34**

Table 2.5-5 — State Estimator Used as Monitoring Tool

State Estimator Features

The survey asked respondents to describe features of their state estimators. The subsections below describe the data reported.

Customization & Application Integration

Table 2-5.6 summarizes the degree to which respondents' state estimators are customized. Table 2.5-7 summarizes responses regarding who developed state estimators for respondents. Table 2.5-8 summarizes the degree of state estimator integration. The results in these tables reflect the fact that good state estimators are commercially available; that is, major SCADA/EMS vendors can provide viable state estimators off the shelf with some customization.

Degree of State Estimator Customization	RC	Other	Total
Off the shelf with some customization	12	7	**19**
Off the shelf	3	8	**11**
Highly customized	2	3	**5**

Table 2.5-8 — Degree of State Estimator Integration

Algorithm Characteristics

The survey asked respondents whether their state estimators solve in one or two passes. Table 2.5-9 summarizes the responses, which indicate that the industry favors using a single-pass over a two-pass solution. According to Koress,[48] single-pass methods perform one estimation that simultaneously addresses internal and external networks. Among the drawbacks of single-pass state estimators are numerical instability problems and "smearing" of bad external system data to the internal system. An alternative one-pass method solves this problem by using a set of critical external pseudo-measurements. The two-pass method involves two state estimations: one for the internal system and another for the external system or for the entire system. Some versions of the two-pass state estimator require a load-flow study for the external system. Both two-pass approaches reduce the effects of boundary errors in the internal system solution by properly weighting the external pseudo-measurements, but they may result in very high or negative loads and generations in the external system.

State Estimator Algorithm	RC	Other	Total
Single Pass (Observable/internal network and non-observable/external network solved together)	12	12	24
Two-Pass (Observable/internal network and non-observable/external network solved separately)	5	6	11
Total	**17**	**18**	**35**

Table 2.5-9 — State Estimator Algorithm

The survey asked respondents how their state estimators handle zero-injection buses. Table 2.5-10 summarizes the results. Zero-injection buses are more commonly treated as high-confidence bus-injection measurements than as hard constraints.

[48] Koress, George N. 2002. "A Partitioned State Estimator for External Network Modeling," *IEEE Transactions on Power Systems*, Vol. 17, No. 3, August.

How Does Your State Estimator Treat Zero-Injection Buses?	RC	Other	All
Hard constraints	5	6	11
High-quality/confidence bus-injection measurements	11	11	22
Total	**16**	**17**	**33**

Table 2.5-10 — Treatment of Zero-Injection Buses

Convergence Tolerance Parameters

The survey asked respondents to identify their voltage-magnitude convergence-tolerance criteria (per unit) for their internal/observable systems (see Table 2.5-11) and for their external/unobservable systems (see Table 2-5.12).

Data	RC	Other	All
Average	0.0053	0.0253	0.0145

Periodicity of State Estimator Execution

The survey asked respondents to describe by what means they trigger their state estimators to run. Table 2.5-15 summarizes the data regarding triggering methods, and Table 2.5-16 details the responses from RCs only. The data in Table 2.5-15 show that 100 percent (35 out of 35) of respondents use periodic triggers for their state estimators. Seventy-one percent (25 out of 35) of respondents, including 71 percent (12 out of 17) of RCs, use manual triggers. Fifty-one percent (18 out of 35), including 59 percent (10 out of 17) of the RCs, use SCADA event triggers (i.e., breaker trips, analog rates of change).

State Estimator Triggering Method	RC	Other	All
Periodic Trigger	17	18	**35**

State Estimator Execution Time (Performance)

The survey asked how long (wall clock time) it usually takes respondents' state estimators to solve. The average state estimator execution time for the 34 respondents to this question ranges from 1 second to 2 minutes. The average execution time for all respondents is about 20 seconds. The median execution time was 10.5 seconds for all respondents and 10 seconds for RC respondents. Average execution times are 10 seconds or shorter for half of the respondents' state estimators (17 out of 34), including 58 percent (10 out of 17) of the RCs' applications. Table 2.5-21 summarizes the results. Table 2.5-22 shows the frequency distribution for the same information.

State Estimator Solution Time (Wall Clock)	RC	Other	All

State Estimator Convergence Rate and Availability

The survey asked respondents to identify their convergence rate metrics and tools. Table 2.5-23 summarizes the results. Fifty percent (17 out of 34) of the respondents, including 53 percent (9 out of 17) of the RC respondents, have state estimator convergence rate metrics as well as tools to compute these metrics.

Do You Have Convergence Rate Metrics and Tools?	RC	Other	All
Yes	9	8	**17**
No	8	9	**17**
Total	17	17	**34**

Table 2.5-23 — State Estimator Convergence Rate Metrics and Tools

The survey asked respondents to indicate how their convergence rates were measured. Of those that responded, 50 percent (8 out of 16), compute the state estimator convergence rate automatically. Table 2.5-24 summarizes the responses. Table 2.5-25 summarizes the time period(s) for which state estimator convergence rates are measured, with detailed data for the reliability coordinator respondents. For respondents that measure state estimator convergence rate, the most common time interval is 1 month. Forty-four percent (4 out of 9) of the reliability coordinator respondents track state estimator convergence rate over multiple time intervals.

How is Your State Estimator Convergence Rate Measured?	RC	Other	All
Automatically	4	4	**8**
Manually	2	3	**5**
Other(s)	3		**3**
Total	9	7	**16**

For What Time Periods is Your State Estimator Convergence Rate Measured? (Please check all that apply and specify a % solution rate for that time period.)	RC01	RC02	RC03	RC04	RC05	RC06	RC07	RC08	RC09	Others	All
Previous Month(s)	X		X			X	X			4	**8**
Previous Hour(s)	X	X	X		X					2	**6**
Previous Week(s)	X	X								1	**3**
Previous Year(s)	X	X						X		0	**3**
Rolling Time Period(s)				X						1	**2**
Selected Time Period(s)				X					X	1	**3**

Table 2.5-25 — Time Periods for State Estimator Convergence Rate Measurements

The survey asked the approximate distribution of respondents' state estimator availability. Table 2.5-26 summarizes the average percentage of time during which state estimators are not available within each duration range. The average period during which state estimator solutions are unavailable is 15 minutes or less for more than 95 percent of all respondents and more than 93 percent of RCs. Note that most respondents -- sixty percent (9 out of 15), and 78 percent (7 out of 9) of RC respondents -- estimate unavailability periods rather than computing them from historical data.

Duration of state estimator unavailability — distribution	RC	Other	All
≤ 15 minutes	93.6	98.5	95.5
15 - 30 minutes	4.1	1.2	3.0
30 - 60 minutes	1.0	0.0	0.7
1 - 4 hours	0.5	0.3	0.4
> 4 hours	0.8	0.0	0.4

Table 2.5-26 — Frequency Distribution of State Estimator Unavailability

The survey asked respondents to indicate how long the state estimator would have to be unavailable to have "significant impact" on their system operations. Table 2.5-27 summarizes the responses. Thirteen percent (2 out of 15) of respondents, including 11 percent (1 out of 9) of RCs, consider unavailability of up to 30 minutes as having no significant impact on operations. Eighty-nine percent (8 out of 9) of the RC respondents cited a "reliability requirement" as the basis for their state estimator unavailability metric. All 6 of the other respondents cited an "internal policy requirement" as the basis for their state estimator unavailability metric. Forty-four percent (4 out of 9) of the RC respondents and 50 percent (3 out of 6) of the other respondents cited market application requirements.

What is the Length of Unavailability That You Consider to Be a Significant Impact on Your System Operation? More than ...	RC	Other	All
1 minute		1	1
10 minutes	1		1
15 minutes		1	1
20 minutes	2	3	5
30 minutes	5		5
60 minutes	1	1	2
Total	**9**	**6**	**15**

Table 2.5-27 — State Estimator Unavailability Considered "Significant" Impact on Operations

Table 2.5-28 summarizes the frequency of state estimator failures that respondents perceive as having a "significant" impact on system operations. Eighty-one percent (13 out of 16) of respondents, including 78 percent (7 out of 9) of RC respondents, experience either occasional or rare state estimator failures that have a significant impact on their operations. Nineteen percent (3 out of 16) of respondents, including 22 percent (2 out of 9) of RC respondents have frequent or very frequent state estimator failures that impact system operations.

Which Best Describes the Frequency of State Estimator Failures That Have a Significant Impact on Your System Operation?	RC	Other	All
Rare — At least one per year on average	3	5	**8**
Occasional — At least one per month on average	4	1	**5**
Very frequent — At least one per day on average	1	1	**2**
Frequent — At least one per week on average	1		**1**
Total	**9**	**7**	**16**

Table 2.5-28 — Frequency of State Estimator Unavailability Considered "Significant" Impact on Operations

State Estimator Solution Quality (Accuracy)

One hundred percent of respondents can detect and identify bad analog measurements and remove them from the state estimator measurement set. The survey asked respondents to quantify the real/reactive power mismatch tolerance criteria for their internal/observable systems. Respondents report a 0.05-170 MW real power mismatch tolerance range and a 0.001-500 Mvar reactive power mismatch tolerance range. The average real and reactive mismatch tolerance criteria were 35 MW and 69.5 Mvar, respectively. Table 2.5-29 summarizes the state estimator convergence criteria for internal system MW mismatch. Table 2.5-30 summarizes the state estimator convergence criteria for internal system Mvar mismatch. The results in Table 2.5-29 and Table 2.5-30 are suspect because zero-injection buses are not treated consistently by all respondents (see Table 2.5-10). Respondents that treat zero-injection buses as hard constraints would be expected to indicate very low real/reactive mismatch tolerances whereas respondents treating zero-injection buses as high-confidence measurements would be expected to have reasonable real/reactive mismatch tolerance values.

Data	RC	Other	All
Average	43.20	17.10	35.00
Median	30.00	1.00	15.00
Max	170.00	50.00	170.00
Min	0.05	0.10	0.05

Data	RC	Other	All
Average	93.700	16.300	69.500
Median	50.000	1.000	40.000
Max	500.000	50.000	500.000
Min	0.001	0.100	0.001
Std Dev	144.300	22.700	124.000
Count	11.000	5.000	16.000

Table 2.5-30 — State Estimator Convergence Criteria for Internal System Mvar Mismatch

The survey asked respondents to quantify the real/reactive power mismatch tolerance criteria for their external/unobservable systems. Respondents report a 0.05-999 MW real power mismatch tolerance range and a 0.001-9999 Mvar reactive power mismatch tolerance range. The average real and reactive mismatch tolerance criteria were 614.7 MW and 665.7 Mvar respectively. Table 2.5-31 summarizes the state estimator convergence criteria for external system MW mismatch. Table 2.5-32 summarizes the state estimator convergence criteria for external system Mvar mismatch. As in the case for the internal/observable system, the results in Table 2.5-31 and Table 2.5-32 are suspect because zero-injection buses are not treated consistently by all respondents (see Table 2.5-10). Respondents that treat zero-injection buses as hard constraints would be expected to indicate very low real/reactive mismatch tolerances values whereas respondents that treat zero-injection buses as high-confidence measurements would be expected to have reasonable real/reactive mismatch tolerance values.

Macedo (2004)[50] states that state estimator MVA mismatch should be less than 10 MVA. He does not distinguish between internal and external systems.

Table 2.5-32 — State Estimator Convergence Criteria for External System Mvar Mismatch

Table 2.5-33 summarizes respondents' state estimator solution quality (accuracy) metrics, showing detailed responses for RCs. The most commonly used state estimator solution quality metric, cost index, is used by 45 percent (10 out of 22) of all respondents and 58 percent (7 out of 12) of RC respondents. The second most commonly used metric is Chi-Squared criteria, used by 36 percent (8 out of 22) of all respondents and 42 percent (5 out of 12) of RC respondents. These metrics are a basis for RTBPTF's recommendation for operating guidelines related to state estimator solution quality.

Table 2.5-34 — Methods for Assessing State Estimator Solution Quality (Accuracy)

Measurement weights (confidences) are important parameters used in the state estimator application that could significantly affect its solution. The survey asked respondents to define weights for telemetered measurements. Table 2.5-35 shows that 78 percent (8 out of 11) of all respondents, including 80 percent (4 out of 5) of RC respondents, use individually defined weights for at least some of the telemetered measurements used by their state estimators. Thirty-six percent (4 out of 11) of all respondents, including 60 percent (3 out of 5) of RC respondents, use globally defined weights for at least some of the telemetered measurements used by their state estimators. The survey also asked respondents to define measurement weights for non-telemetered measurements. Table 2.5-36 summarizes the responses. Fifty-five percent (6 out of 11) of all respondents, including 60 percent (3 out of 5) of RC respondents, use globally defined weights for at least some of the non-telemetered measurements used by their state estimators (i.e., modeled loads and generator outputs). Fifty-five percent (6 out of 11) of the respondents, including 60 percent (3 out of 5) of RC respondents, use individually defined weights for at least some of the non-telemetered measurements used by their state estimators (i.e., modeled loads and generator outputs).

How do You Define Measurement Weights for Telemetered Measurements?	RC01	RC02	RC03	RC04	RC05	Others	Total
Measurements have individually defined weights		X	X	X	X	4	**8**
Globally defined weights by measurement type (e.g., line measurements, transformer MW/Mvar)	X		X		X	1	**4**
Others						1	**1**

Table 2.5-35 — Weights for Telemetered Measurements

How do You Define SE Measurement Weights for Non-Telemetered Measurements? (Please check all that apply.)	RC01	RC02	RC03	RC04	RC05	Others	All
Globally defined weights by type (e.g., non-telemetered loads, non-telemetered generators)	X		X		X	3	**6**
Measurements have individually defined weights			X	X	X	3	**6**
Other(s)		X					**1**

Table 2.5-36 — Weights for Non-Telemetered Measurements

The survey asked respondents to characterize their basis for assigning weights to model measurements. Table 2.5-37 summarizes the responses for SCADA analog measurements (excluding measurements from ISN and other data links). Forty-five percent (5 out of 11), including 60 percent (3 out of 5) RC respondents, use generic percentage metering errors as the basis for weights applied to at least some analog values used by their state estimators. Twenty-seven percent (3 out of 11), including 40 percent (2 out of 5) of RC respondents, use actual meter accuracies as the basis, and 27 percent (3 out of 11) use other methods besides actual meter accuracies or generic meter error percentages.

What is the Basis for Your SCADA Analog Measurement Weights (excluding measurements from ISN and other data links)?	RC01	RC02	RC03	RC04	RC05	Others	All
Generic percentage meter error for each measurement type	X			X	X	2	**5**
Actual meter accuracies associated with each individual measurement						3	**3**
Other(s)		X	X			1	**3**

Table 2.5-37 — Basis for SCADA Analog Measurement Weights

Using State Estimator to Monitor External Facilities

Monitoring external facilities using the state estimator is highly dependent on the modeling practices related to external facilities. State estimator solution quality including external facilities depends on the accuracy with which external facilities are modeled. Section 4.1, Model Characteristics, and Section 4.2, Modeling Practices and Tools, discuss external system modeling practices in detail.

The external network models that are currently in use could affect the quality of state estimator solutions by:

- **Propagation of errors into the internal model solution from the external model solution**. This concern applies to one-pass state estimators if the external network model solution is mainly based on forecasted and/or pseudo-measurements rather than telemetered data. The external network model equivalencing methodology could also cause errors to propagate. For systems that use a two-pass state estimator, there could be boundary problems (between the internal/observable solution and the external/unobservable solution) that could cause the total network solution to not converge.

- **Measurement density in the external system**. Findings in Section 4.1 indicate that many buses in external models are measurement unobservable. The low values for the external-status-point-to-external-bus ratios for many respondents (i.e., less than one status point per bus) indicates that many external buses do not have telemetered breaker/switch information, which implies a bus-branch type external model (i.e., a planning model) for many buses. The lack of real-time telemetry data in MISO's external model was one of the contributing factors in the 2003 blackout. The *Outage Task Force Final Blackout Report* indicates that MISO was using a static bus-branch network model in parts of its external model. When the Stewart- Atlanta 345-kV line tripped (monitored by the PJM reliability coordinator), MISO's state estimator did not know the line had gone out of service. This led to a data mismatch that prevented MISO's state estimator from computing a solution that could be used by its real-time contingency analysis application.[51]

- **Convergence issues related to external models and/or telemetry data for external model**. Measurements for the external network model usually originate from ICCP (or equivalent) data links. Therefore, data availability depends on data-link availability. Another factor is the time skew of data supplied by the external network model measurements; time skew is highly dependent on the periodicity of the data-link data.

- **Interchange transaction impacts.** The impact of interchange transactions, especially for the external portion of the model, could greatly affect the state estimator solution.

- **Throughput because of external model expansion/detail**. Adding detail or expanding the external network model could affect the throughput (execution time) of the state estimator application.

In response to the 2003 blackout, many survey respondents are expanding and/or adding more detail to their external network models. As mentioned in Section 4.1, Model Characteristics, approximately 88 percent (15 out of 17) of RC respondents and 75 percent (18 out of 24) of other respondents indicate that in the coming year they plan to make "major" changes to their network models above and beyond what is considered "routine" model maintenance. Table 2.5-38 summarizes the types of changes planned. These changes will greatly impact state estimator solution quality. The observations cited in Table 2.5-38 suggest that most near-term major changes will be related to external network model improvements. For RCs, these types of changes will enhance wide-area analysis capabilities provided by the reliability analysis applications recommended by Macedo (2004)[52.]

Other(s)		X	X			1	**3**

Table 2.5-39 — Basis for ISN (and other data link) Analog Measurement Weights

Presentation of State Estimator Results

The survey asked respondents to describe how their state estimator solution is presented in visualization tools (i.e., state estimator one-line displays). (Section 2.1, Visualization Techniques, of this report discusses usage and prevalence of state estimator one-line displays.) Of the 35 respondents that have working state estimators, 97 percent (34 out of 35), including 100 percent (17 out of 17) of RC respondents, use some type of state estimator one-line display. Sixty-five percent (22 out of 34) overlay the state estimator values on SCADA one-line displays so that estimated values can be seen along with raw values. Thirty-five percent (12 out of 34) display state estimator results separately from SCADA one-lines. Among RC respondents, 47 percent (8 out of 17) overlay state estimator results on existing SCADA one-line displays, and 53 percent (9 out of 17) display state estimator results on separate one-line displays. Table 2.5-40 summarizes the results.

State Estimator One-Line Displays	RC	Other	All
State estimator one-lines are overlays of SCADA one-lines	8	14	**22**
State estimator one-lines are separate from SCADA one-lines	9	3	**12**
Do not have state estimator one-lines	0	1	**1**
Total	17	18	**35**

Table 2.5-40 — Presentation of State Estimator Results

State Estimator Maintenance/Troubleshooting Practices

The majority of respondents can notify operators and control room staff of a state estimator failure. State estimator status is presented primarily via alarm tools and physical displays although a few respondents can page and send email.

The survey asked respondents whether they have a process to investigate and de-bug unsolved/non-converged and bad/inaccurate state estimator solutions. Ninety-four percent (29 out of 31) of those that responded, including 94 percent (15/16) of RC respondents, investigate unsolved state estimator solutions. Table 2.5-41 summarizes the responses.

Do You Investigate Unsolved or Non-Converged State Estimator Solutions?	RC	Other	All
Yes	15	14	**29**
No	1	1	**2**
All	16	15	**31**

Table 2.5-41 — Investigation of Unsolved or Non-Converged State Estimator Solutions

The survey also asked respondents whether their operators attempt to resolve state estimator problems prior to notifying support personnel. Table 2.5-42 summarizes the results. Fifty-three percent (15 out of 28) of all respondents, including 60 percent (9 out of 15) of RC respondents, have operators attempt to resolve state estimator convergence problems prior to notifying EMS support personnel.

Do Operators Attempt to Resolve State Estimator Problems Prior to Notifying Support?	RC	Other	All
Yes	9	6	**15**
No	6	7	**13**
Total	15	13	**28**

Table 2.5-42 — State Estimator Problem-Resolution Practices

The survey asked respondents about state estimator maintenance and support. Table 2.5-43 summarizes the responses. The table illustrates that 100 percent (28 out of 28) of all respondents, including 100 percent (15 out of 15) of RC respondents maintain their state estimators with in-house staff. However, 18 percent (5 out of 28), including 27 percent (4 out of 15) of RC respondents, use vendor staff in addition to in-house staff for support.

Who Maintains Your State Estimator?	RC	Other	All
In-House Staff	15	13	**28**
Vendor Staff	4	1	**5**

Table 2.5-43 — State Estimator Maintenance and Support

The survey asked respondents whether they continuously monitor the status of their state estimators (i.e., 24 hours per day, 7 days per week, 365 days per year). Table 2.5-44 summarizes the responses. Seventy-five percent (27 out of 36) of all respondents that have operational state estimators responded to this question. Of those that responded, 89 percent (24 out of 27), including 93 percent (14 out of 15) of RC respondents, continuously monitor state estimator status 24 x 7 x 365. The respondents were also asked whether their state estimator support personnel are available continuously (24 x 7 x 365). There were 28 respondents to this question, including 15 RCs; Table 2.5-45 summarizes the results. Ninety-three percent (26 out of 28) of all respondents, including 93 percent (14 out of 15) of RC respondents, have state estimator support personnel available continuously.

Recommendations for New Reliability Standards

The state estimator is mainly used:

- as a base case for reliability analysis applications (e.g., contingency analysis, power flow), and
- as input to other operator monitoring tools (e.g., alarm, wide-area visualization).

Wollenberg (2006)[53] says:

[53] Wollenberg, Bruce. 2006."ERO Standards: What Should They Cover." *IEEE Power & Energy Magazine*, Volume 4 (4), July/August: 96.

> The state estimator is the first of the major application programs that runs as new data are gathered from the power system into an operations computer system. If the state estimator fails, then the remaining applications ([optimal power flow] OPF, security analysis, etc.) cannot be run — the operator is blind. To quote Brian Stott, "By now, it ought to be (and is not) a SCANDAL if a company's state estimator does not produce a reliably accurate real-time power system model virtually 100% of the time." So what does it take to achieve a 100% reliable state estimator? First it takes a well-thought-out and maintained metering system, a well-maintained communications system, a constantly updated database containing the power system model, and, last of all, a state estimator algorithm designed not to fail when some critical measurements are missing.

The results of the RTBPTF survey detailed in the previous section support the assertion of Macedo (2004)[54] that a state estimator is a minimum requirement, i.e., an essential tool for operators. Figure 2.5-1 shows a slide from Macedo (2004) on the topic of network analysis, which implies that a state estimator should execute every two minutes and should have a solution accuracy of less than 10 MVA mismatch. RTBPTF agrees with Macedo's assessment that a state estimator is a minimum requirement (i.e., a critical real-time tool) but does not agree that the state estimator needs to execute every 2 minutes at a minimum. In lieu of measuring the triggering periodicity of state estimator, RTBPTF recommends measuring state estimator availability (for a given, reasonable periodicity required by other reliability analysis applications). RTBPTF also recommends measuring state estimator solution quality. RTBPTF believes that state estimator availability and adequate solution quality are measures that can ensure a robust and accurate reliability monitoring tool for operators. The state estimator availability and state estimator solution quality recommendations are discussed in detail in the following subsections below.

[54] Macedo, Frank. 2004. *Reliability Software: Minimum requirements and Best practices*. FERC Technical Conference. July 14. http://www.ferc.gov/EventCalendar/Files/20040716092511-20040714085315-FrankMacedo.pps

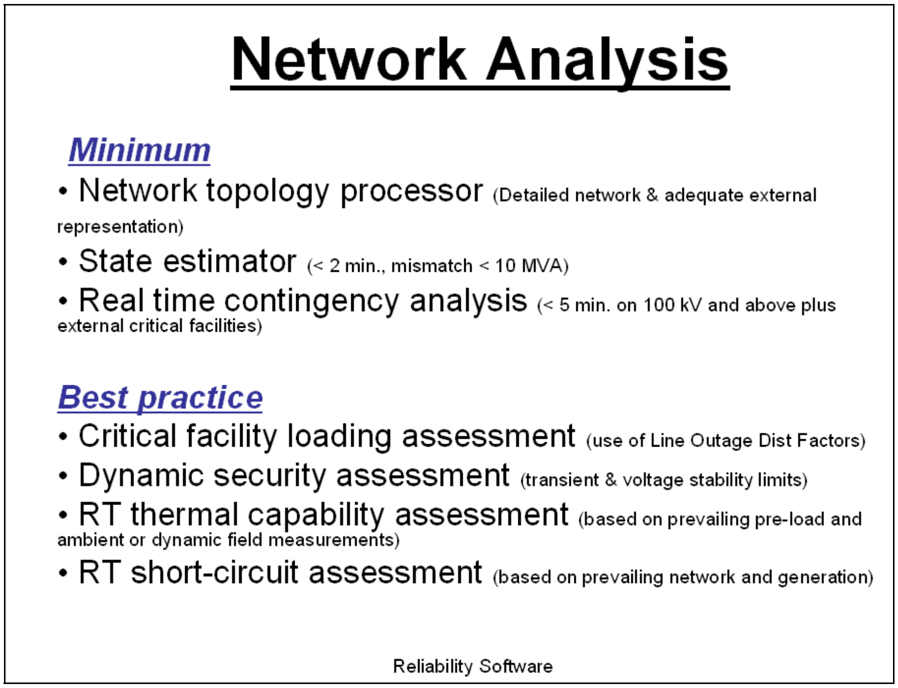

Figure 2.5-1 — Copy of Slide on Network Analysis (Macedo 2004)

Recommendation – S1

Mandate the following reliability tools as mandatory monitoring and analysis tools

- Alarm Tools
- Telemetry Data Systems
- Network Topology Processor
- State Estimator
- Contingency Analysis

State Estimator: Mandatory Monitoring and Analysis Tool

Survey results indicate that state estimators are inherently delivered as part of commercially available modern SCADA/EMS systems. RTBPTF believes that a state estimator is essential for operators to monitor and maintain the reliability of the bulk electric system. Existing NERC reliability standards implicitly assume the use of state estimators to aid RCs and TOPs in maintaining situational awareness for the bulk electric system. Standard IRO-002 (Requirement R7) states "[e]ach Reliability Coordinator shall have ***adequate analysis tools*** [emphasis added] such as ***state estimation*** [emphasis added], pre and post-contingency analysis capabilities (thermal, stability, and voltage), and wide area overview displays." Specifying the state estimator as part of the Reliability Toolbox[55] clarifies current NERC reliability standards by indicating that the state

[55] See the Reliability Toolbox Rationale and Recommendation section.

estimator, as defined, is mandatory. It also clarifies the term "adequate analysis tools."

Recommendation – S11

Specify and measure minimum availability for state estimator, including a requirement for solution quality.

State Estimator Availability

If the state estimator is mandatory for bulk electric system situational awareness, it must be highly available and redundant. Awareness of state estimator availability is discussed in the recommendations in Section 5.4, Critical Applications Monitoring. However, a more detailed awareness (via a requirement for state estimator availability) of state estimator availability is necessary than what is described in Section 5.4; in particular, a metric measuring "adequate" availability should be established.

RTBPTF Recommendation

RTBPTF recommends adding the following new requirement to Standard TOP-006 to measure state estimator availability:

PR2. State Estimator Availability. Each reliability coordinator and transmission operator shall operate its state estimator based on the following metrics:

a. State Estimator Availability Metric 1 (SEA1): Each reliability coordinator and transmission operator shall operate such that its state estimator shall have at least one converged solution (i.e., produce a state-estimate solution) for at least 97.5 percent of 10-minute clock periods (i.e., six non-overlapping periods per hour) during a calendar month.

b. State Estimator Availability Metric 2 (SEA2): Each reliability coordinator and transmission operator shall also operate such that its state estimator shall have at least one converged solution (i.e., produce a state-estimate solution) for every continuous 30-minute interval during a calendar day.

RTBPTF recommends the following measures (see PM2a and PM2b) for the state estimator availability requirements stated above. To validate the effectiveness of the metrics, RTBPTF recommends that a pilot program (or field trial) be conducted to analyze the metrics' effectiveness.

PM3. Measures for State Estimator Availability

PM2.1. The responsible entity shall achieve, at a minimum, Requirement PR2a (SEA1) compliance of 97.5 percent. SEA1 is calculated by converting a state estimator availability ratio to a compliance percentage as follows:

$$SEA1 = \left[1 - \frac{V_{month}}{TP_{month}}\right] * 100$$

$$where:$$

$$V_{month} = \text{Violations per month}$$

$$TP_{month} = \text{Total Periods per month}$$

The violations per month are a count of the number of periods (10-minute clock periods) during which the state estimator does not have at least one converged solution. Each responsible entity shall report the total number of violations for the month.

PM2.2. The responsible entity shall achieve no SEA2 violations per day. One SEA2 violation equates to the state estimator not having at least one converged solution for a period of 30 contiguous minutes (three consecutive 10-minute clock periods), for example, if the state estimator is unavailable continuously for 40 minutes (no converged solution within four consecutive 10-minute clock periods), SEA2=1 for the calendar day or if the state estimator is unavailable continuously for 60 minutes (no converged solution within six consecutive 10-minute clock periods, SEA2=2 for the calendar day. For the purpose of simplicity, when the state estimator remains unavailable through midnight on any day (i.e., through a transition in calendar days), the SEA2 calculation shall be attributed to the previous calendar day. Each responsible entity shall report the total SEA2 violations per month.

Rationale

Recommended requirements PR2a and PR2b measure the availability of the state estimator solution for RCs and TOPs. PR2a is consistent with the NERC mandate for MISO to fully implement and test its state estimator and contingency analysis tools “to ensure they can operate reliably no less than every ten minutes.”[56] Recommended requirement PR2b ensures that the state estimator is unavailable for no more than 30 minutes during a calendar day; this would prevent prolonged periods of unavailability that would negatively affect situational

[56] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April. p. 152.

awareness. RTBPTF believes that these availability requirements (SEA1 and SEA2) are consistent with the mandate that operators be aware of potential IROL/SOL violations and have 30 minutes to take the necessary actions to correct/prevent violations. Together with contingency analysis, the state estimator is a critical application that determines potential IROL/SOL violations.

RTBPTF believes that requiring RCs and TOPs to have an available state estimator solution at least once every 10 minutes 97.5 percent of the time will greatly enhance situational awareness. The feasibility of requirements SEA1 and SEA2 is based on the survey data regarding current state estimator availability. Survey data described earlier support the technical feasibility of the state estimator availability requirements as follows:

- The average wall clock (in seconds) execution time for state estimators is 28.9 seconds.
- The average trigger periodicity for state estimator is 319 seconds.
- The most common trigger periodicity for automatic triggers is 5 minutes.
- State estimator unavailability is less than 15 minutes 95.5 percent of the time.
- Eighty-eight percent (15 out of 17) of all survey respondents consider lapses in availability of 30 minutes or longer to significantly impact their operations.

RTBPTF believes that the recommended state estimator availability requirements are reasonable targets based on the survey results.

State Estimator Solution Quality

The state estimator must be highly available and must also be able to provide a reasonable, accurate, robust solution that fulfills the purposes for which it is intended.

RTBPTF Recommendation

RTBPTF recommends that a state estimator solution-quality requirement be established. However, RTBPTF had difficulty formulating specific, technically defensible state estimator solution-quality metrics. The Real-Time Tools Survey did not sufficiently address the issue of the current practices/methods in determining state estimator solution quality. Therefore, RTBPTF believes that state estimator solution-quality metrics warrant further investigation and development. RTBPTF recommends that the SAR process be initiated to define specific, technically defensible state estimator solution-quality metrics.

RTBPTF recommends adding the following new requirement in Standard TOP-006 in order to measure state estimator solution quality:

PR3. State Estimator Solution Quality. Each reliability coordinator and transmission operator shall operate such that its state estimator shall have sufficient solution quality for each converged case.

RTBPTF believes there is no single metric for state estimator solution quality. The survey revealed various methods for assessing state estimator solution quality but these methods were highly dependent on the type of state estimator algorithm being used. RTBPTF recommends that NERC (through the SAR process) develop and define state estimator solution-quality metrics. Pending this development, RTBPTF recommends a possible set of state estimator solution-quality metrics as operating guidelines until mandatory solution-quality metrics are established. Based on the Requirement PR3, RTBPTF recommends the following measure:

PM4. Each reliability coordinator and transmission operator shall have and provide upon request evidence of calculations that demonstrate state estimator solution quality for each converged case.

Rationale

RTBPTF recommends that state estimator availability requirements be augmented by solution-quality requirements to ensure that operators are provided with accurate information so they can be fully aware of the system situation at any given time. Requirement PR3 mandates that RCs and TOPs be cognizant of state estimator solution quality in tandem with complying with the state estimator availability requirement PR2.

Applicability Statement for Recommended Standards

RTBPTF recommends that all RCs and TOPs be required to have a state estimator for monitoring bulk electric system elements and critical reliability parameters as defined in the recommended additions or modifications to the NERC standards applicable to RCs and TOPs. Other responsible entities who use state estimators to support or complement their RCs' ability to operate the bulk electric system reliably in accordance with formal agreements, contracts, or established practices or procedures shall be subject to the same standards for the state estimator as their RCs.

Recommendations for New Operating Guidelines

The subsections below describe recommended guidelines for state estimator operation.

Recommendation – G4

Establish state estimator solution-quality metrics to ensure accurate data and other reliability analysis.

Operating Guidelines for State Estimator Solution Convergence Parameters

It is difficult to recommend specific state estimator voltage and angle convergence tolerances because of the different algorithms employed by different state estimators and the manner in which specific convergence parameters are used in these algorithms. For example, some state estimators check convergence based on changes of the absolute values of voltage magnitudes and voltage phase angles (relative to ground) between successive iterations. At least one vendor bases convergence on changes between successive iterations on voltage magnitude drops and angle differences across branches. There are other approaches as well. Table 2.5-47 summarizes the survey responses for internal and external system voltage and angle convergence tolerances.

Statistic	Internal Voltage Convergence Tolerance	Internal Angle Convergence Tolerance	External Voltage Convergence Tolerance	External Angle Convergence Tolerance
Average	0.0145	0.0143	0.0140	0.0127
Median	0.0065	0.0063	0.0080	0.0075
Max	0.1000	0.1000	0.1000	0.1000
Min	0.0001	0.0001	0.0001	0.0001
Std Dev	0.0269	0.0262	0.0230	0.0216
n	26	26	23	23

Table 2.5-47 — Internal and External System Voltage and Angle Tolerances

From the summary statistics in the table above, we see there is a wide range in survey responses (from 0.0001 to 0.1). However, a review of the individual responses (not shown) reveals that the overwhelming majority of voltage magnitude and voltage angle convergence tolerances are under 0.01 kV per unit and 0.01 radians, respectively. These values essentially represent a “lowest common denominator.” The median responses are well under 0.01 kV per unit and 0.01 radians. Based on these observations, RTBPTF recommends that voltage magnitude and voltage angle convergence tolerances should be set to values no greater than the median values listed in Table 2.5-47. These are reasonable, achievable, and non-restrictive tolerances for most state estimator algorithms.

Operating Guidelines for State Estimator Solution-Quality Metrics

RTBPTF recommends that Operating Guidelines for state estimator solution-quality metrics be established that would apply until technically defensible metrics are developed. RCs need a high-quality estimation of the state of the bulk power system elements within their wide-area view to provide accurate data to other reliability analysis and market applications. Tools such as contingency analysis and power flow are highly dependent upon the state estimator's solution quality. For TOPs to maintain situational awareness of their "local" transmission systems, an accurate state estimator solution is required. An accurate solution is also necessary for other reliability analysis applications to determine the cause(s) of SOL violations. Table 2.5-3 details the applications that depend on the state estimator for the reliability coordinators and transmission operators. Table 2.5-48 lists the state estimator solution-quality metrics currently used by survey respondents.

Table 2.5-48 — State Estimator Solution-Quality (Accuracy) Metric

The quality of the state estimator solution should be measured using one or more of the metrics below; most of these recommended metrics are based on the survey results shown in Table 2.5-48 above. The reliability entity should track this set of metrics over time to gauge the pattern and determine what signals a problem with state estimator solution quality. Deviation from the "normal range" of these metrics should trigger state estimator maintenance and support. Even though no criteria for state estimator solution quality metrics are recommended at this time, these metrics are important because they could affect the contingency analysis solution.

The following metrics were not based on the survey results but rather on internal discussions within RTBPTF regarding recommending guidelines to the industry to assess state estimator solution quality.

1. *Cost Index*
   Cost index is also referred to as "Performance Index" or "Quadratic

Cost." In general, it measures the sum of the squares of the normalized estimate errors (residuals). Increasing cost index values could indicate deteriorating state estimator solution quality. See inset for a technical discussion.[57]

Technical Discussion of Cost Index

$$J(\hat{x}) = \sum_{j=1}^{m} \left[\frac{z_j - h_j(\hat{x})}{\sigma_j} \right]^2$$

where:

J is the "cost index" (sometimes called "performance index" or "quadratic cost")

m is the number of measurements being used in the estimate (excludes those that have been flagged bad and omitted)

z_j is the j^{th} measurement value (voltage, MW, Mvar, tap measurement, etc.)

$\hat{x}$ is a vector of estimated state variables (voltage magnitudes, voltage phase angles, etc.)

σ_j is the standard deviation of the metering error associated with measurement z_j (it is the inverse of the measurement weight)

$h_j(x)$ is a non-linear vector function that relates the state variable vector to measurement z_j.

The theoretical expected value of $J(\hat{x})$ is m-n where "m" is the number of measurements used in the estimate and "n" is the number of state variables. The theoretical variance of $J(\hat{x})$ is 2(m-n). Note that if the only state variables are voltage magnitudes and voltage phase angles, the value of n = 2b-1 where b is the number of electrical buses. The value of n will be greater if transformer taps and other quantities are used as state variables.

2. *Chi-squared Test*
   The Chi-squared test is a statistical test against the cost index to determine the presence of measurements that are inconsistent with estimated values; these could be bad measurements, topology errors, etc. This test is often used as a trigger for anomaly detection processing. Tracking the number of anomalous measurements could aid entities in tracking state estimator solution quality over time. Increasing numbers of anomalous measurements could indicate deteriorating state estimator solution quality. See inset for a technical discussion.[58]

[57] Grainger, John J., and William D. Stevenson, Jr. 1996. *Power System Analysis*. McGraw-Hill, Inc.
[58] Ibid.

Technical Discussion of Chi-Squared Test

If one assumes that all of the measurements used by the state estimator have errors that are independent of each other, follow a normal distribution, each having a mean of zero, then the cost index, $J(\hat{x})$, follows a chi-squared distribution with m-n degrees of freedom (where "m" is the number of measurements and "n" is the number of state variables). Under these conditions, the expected value of $J(\hat{x})$ is equal to m-n, and the expected value of its variance is equal to 2(m-n). Tabulated values of chi-square ($\chi^2_{m-n,a}$) associated with a given number of degrees freedom (k=m-n) and probability (α) are available in statistical tables or can be computed from formulas. If the computed value of $J(\hat{x})$, where $\hat{x}$ is a vector of estimated state variables, is less than or equal to $\chi^2_{m-n,a}$, there is a (1-α)*100% probability that there are no bad input measurements, or conversely, a α*100% probability that there is at least one or more bad input measurements. Therefore, if $J(\hat{x}) \leq \chi^2_{m-n,a}$ then the estimated state variables are considered "good". If $J(\hat{x}) > \chi^2_{m-n,a}$ then there is at least once bad measurement in the input and error processing must be done to locate and remove the bad measurement(s) from the inputs. A common procedure for eliminating bad measurements using the chi-square test is as follows:

1. Use the raw measurements $z_1, z_2, \ldots, z_m$ from the system to determine the least squares estimates of the state variables x, or $\hat{x}$.
2. Compute the estimated values of z, $\hat{z}$, from the estimated state variables using the relation $h(\hat{x})$.
3. Evaluate $J(\hat{x}) = \sum_{j=1}^{m} \left[\dfrac{z_j - h_j(\hat{x})}{\sigma_j} \right]^2$
4. For the appropriate number of degrees of freedom (m-n) and a user specified probability, α, determine whether or not $J(\hat{x}) \leq \chi^2_{m-n,a}$. If this is satisfied then the estimated state variables are accepted as being accurate and processing is done.

If $J(\hat{x}) > \chi^2_{m-n,a}$ then there is at least one suspect measurement in the measurement input. In this case use an algorithm)) to omit the "bad" measurements and then go back to step 1 above (i.e., remove the measurement(s) with the largest standardized error(s).

3. *Ranked Normalized Residual*s
   Normalized residuals are normalized individual estimate errors. Ranking normalized residuals in descending order aids entities in detecting causes of bad state estimator solutions based on specific measurements. Measurements that consistently rank high could indicate bad telemetry/measurement data.

4. *Maximum MW/Mvar Mismatch*
   The maximum MW/Mvar mismatch metric is applicable to state estimator algorithms that treat zero-injection buses (i.e., buses that do not have a load or generator connected to them) as high-confidence measurements. Macedo (2004)[59] says that state estimator MVA mismatch should be less than 10 MVA. Macedo does not distinguish between internal and external footprints; however, the survey results indicate some state estimators have the capability to track the maximum MW/Mvar mismatch on an internal and external basis. RTBPTF is not recommending specific values for internal/external MW/Mvar mismatch parameters. However, RTBPTF believes that where this capability exists, reliability entities should track both internal and external maximum MW/Mvar mismatch and observe trends over time. Sudden increases or an upward trend in maximum MW/Mvar mismatch could indicate deteriorating state estimator solution quality.

5. *Number of Iterations*
   Keeping track of the number of state estimator iterations over a period of time could provide information indicative of state estimator solution quality. The reliability entity should establish a normal range of state estimator iterations based on its model. If solution convergence exceeds these norms, state estimator results should be investigated.

6. *Major Topology Changes*
   Tools that keep track of major topology changes from one state estimator run to the other could help in tracing problems caused by changing topology of the network model.

[59] Macedo, Frank. 2004. *Reliability Software: Minimum requirements and Best practices*. FERC Technical Conference. July 14. http://www.ferc.gov/EventCalendar/Files/20040716092511-20040714085315-FrankMacedo.pps

Factors Affecting State Estimator Solution-Quality Metrics

The values of the state estimator solution-quality metrics may depend upon many factors including:

1. **Modeling of electrical devices, connectivity, and mapping of telemetry data**. In state estimation, network topology is treated as given and assumed to be correct. If topology is incorrect, the state estimator may not converge or may yield grossly incorrect results. A topology error may stem either from:
   - Inaccurate status of breakers and switching devices, or
   - Errors in the network model.

   (Note that inaccuracies in the status of switching devices may be caused by a temporary or permanent loss of telemetry data)

2. **Availability and quality of telemetry data**. Telemetry data are essential components of the state-estimation process, as discussed extensively in Section 1.1,Telemetry Data, of this report.

3. **Inadequate Observability**. State estimation is extended to the unobservable parts of the network through the addition of pseudo-measurements. Pseudo-measurements are computed based on load prediction using load distribution factors, or they can represent non-telemetered generation assumed to operate at a base-case output level. The quality of pseudo-measurements may be questionable if they are not updated regularly to reflect current conditions. Note that when performing state estimation for the unobservable part of the network, it is possible to corrupt the states estimated from telemetry data.

4. **Measurement redundancy of the network**. This term is defined as the ratio of the number of measurements to the number of state variables in the observable area of the network.

Recommendation – A6

Identify minimum measurement observables, adequate redundancy, and critical measurements to improve state-estimator observability and solution quality.

Areas Requiring More Analysis

RTBPPTF recommends that the following areas be considered for further analysis. The Real-Time Tools Survey did not go in detail on these areas.

1. Minimum Measurement Observability
   The state estimator should be capable of monitoring the transmission network so that the estimator has sufficient measurements to calculate the voltage and angle at each bus. Without this minimum information, operators cannot know the real-time flows and expected post-contingency flows on the transmission system. Note that observability defines the percentage of the network meeting this minimum requirement. Current research and development in incorporating PMUs into the state estimator claims improved state estimator observability and solution quality.[60]

2. Inadequate Redundancy
   Redundant measurements are crucial for detecting and identifying bad data. Higher redundancy also ensures a more reliable state estimator solution in the face of a temporary loss of measurements. A bus measurement is observable if its state can be estimated using measured data without reliance upon pseudo-measurements, such as measurements from load or transformer tap models. Redundancy is a measure of the ability to maintain observability when access to telemetry data is lost. Critical measurements are those for which observability (in terms of the state estimator) will be lost if the measurement is lost. More investigation is needed for other appropriate measures such as the redundancy ratio (the total number of measurements divided by the total number of state variables) and the percent measurement of observable buses by kV level. The intent is to provide a state estimation driven by measurements as opposed to pseudo-measurements, which will minimize islands of poor measurement observability.

3. Critical Measurements
   The state estimator should be able to identify critical measurements in the system whose loss will result in either:
   - An inability to monitor a loading on a transmission element operated at high voltage and identified as critical to the system, or
   - An inability to monitor loading on a high-voltage autotransformer that is identified as critical to the system.

[60] See the following website:
http://www.pserc.wisc.edu/ecow/get/generalinf/presentati/psercsemin1/2psercsemin/abur_pmu_pserc_teleseminar_nov2005_slides.pdf#search=%22zero%20injection%20bus%20state%20estimator%22.

Recommendation – A7

Establish a pilot program to collect data and build appropriate state estimator performance metrics.

Additionally, RTBPTF recommends establishing a pilot program of a few RCs/TOPs that represent the individual systems, to collect data that could be used to establish the appropriate performance metrics. The pilot program would:

1. Review the recommended standards and devise a test plan.
2. Test the recommended standards for availability.
3. Recommend changes or additions to the recommended standards for availability.
4. Identify metrics for solution quality (accuracy) that have global applicability.
5. Test the identified metrics for solution quality.
6. Recommend standards (if possible) for state estimator solution quality.

Examples of Excellence

RTBPTF cites the unique approach taken by MISO to ensure that its state estimator provides the information necessary for operators to maintain situational awareness as an example of excellence (See EOE-8 in Appendix E).

Section 2.6
Contingency Analysis

Definition

Contingency analysis is a computer application used to analyze the impact on power system security of specific, simulated outages (lines, generators, or other equipment) or higher load, flow, or generation levels. Contingency analysis identifies problems such as line overloads or voltage violations that will occur if a new system event (contingency) takes place. The state estimator solution represents current system conditions and usually serves as the base case for contingency analysis. The information a contingency analysis generates enables RCs and TOPs to implement mitigation plans in advance of a contingent event such as a line trip. Contingency analysis is used as a real-time application as well as for studying potential scenarios. This section discusses both types of contingency analysis.

Background

The NERC Steering Group *Technical Analysis of the August 14, 2003 Blackout*[61] concludes that a nonfunctional contingency analysis was a key cause of the blackout:

> Cause 1e: FE did not have an effective contingency analysis capability cycling periodically on-line and did not have a practice of running contingency analysis manually as an effective alternative for identifying contingency limit violations. Real-time contingency analysis, cycling automatically every 5–15 minutes, would have alerted the FE operators to degraded system conditions….

NERC reliability standards IRO-005 and TOP-004 require all RCs and TOPs to monitor post-contingency conditions of bulk electric system elements. Most commonly, a real-time contingency analysis application is used to monitor potential post-contingency voltage and thermal violations.

NERC Reliability Standard TPL-002, System Performance Following Loss of a Single Bulk Electric System Element, is a planning standard. It requires that a transmission system be planned so it can be operated reliably following a Category-B contingency. As defined in this same standard, a Category-B contingency is an event that results in the loss of a single element of the bulk electric system, such as s generator, transformer, or transmission circuit, due to a single-line ground or 3-phase fault with normal clearing or the loss of an

---

[61] Technical Analysis of the August 14, 2003, Blackout: *What Happened, Why, and What Did We Learn?* Report to the NERC Board of Trustees by the NERC Steering Group - July 13, 2004, page 96.

element without a fault. None of the operating standards, including the IRO and TOP series, contains an equivalent definition of a real-time contingency.

In a real-time operating environment, one or more elements are often out of service for maintenance or other reasons. Operators must be able to analyze and respond to any event that reasonably could cause the loss of an additional element, i.e., the next contingency. At a practical level, events that result in activation of protective relays are the most common causes of the next contingency. Consequently, real-time contingencies must be defined that accurately reproduce the results of activating protective relays, which are intended to remove elements from service to minimize damage or stop the spread of undesirable system conditions. Because more than one element is sometimes removed, it is insufficient to define a real-time contingency as a single element. A contingency must be defined as the set of circuit breakers or other automatic devices designed to clear a fault or otherwise respond to activation of protective relays that remove an element from service.

RTBPTF considers contingency analysis an essential tool for enabling operators to monitor and maintain the reliability of the bulk electric system. Macedo (2004)[62] states that real-time contingency analysis is a minimum requirement for network analysis tools for grid reliability and implies that operators should perform contingency analysis at least every 5 minutes on all facilities that operate at or above 100 kV within the RC area and on critical external facilities. RTBPTF agrees with Macedo's assessment that contingency analysis is a minimum requirement but does not agree that it must be performed every 5 minutes. In lieu of requiring a specific interval of execution, RTBPTF recommends requiring that contingency analysis solutions be produced within a reasonable interval in order to detect potential SOL/IROL violations. RTBPTF believes that the accuracy of contingency analysis solutions over time provides a quantifiable measure of the application's overall performance.

This Contingency Analysis section of the Real-Time Tools Survey examines the applications that RCs, TOPs, and BAs use to analyze the effects of contingent events. RTBPTF classifies real-time contingency analysis as a critical real-time tool.

Summary of Findings

All RCs and most other respondents to the contingency analysis section of the survey have a functional contingency analysis application, and most consider it an essential tool for system reliability. This section describes what respondents report about their contingency analysis applications, how they are integrated with other systems and alarms, and how the applications and their various features

[62] Macedo, Frank. 2004. *Reliability Software Minimum Requirements & Best Practices*. FERC Technical Conference, July 14. Available at: http://www.ferc.gov/EventCalendar/Files/20040716092511-20040714085315-FrankMacedo.pps

are valued. Because RTBPTF finds contingency analysis to be an essential tool for monitoring the elements of the bulk electric system, RTBPTF recommends that all RCs and TOPs be required to have contingency analysis for their areas of operation and that reliability parameters be established for the applications. Survey results reveal the need to establish requirements for the quality of solutions derived from contingency analysis. Survey results also reveal the need to establish criteria for identifying which internal and external facilities should be included in the set of contingent elements to be analyzed.

Prevalence of Applications

All 17 RCs and approximately 54 percent of all other respondents (15 out of 28) have a functional contingency analysis application. Of the 13 respondents who have no such application, 8 plan to add one. Tables 2.6-1 and 2.6-2 summarize the reported prevalence of contingency analysis applications. RC responses are noted separately.

Do You Have Contingency Analysis?	RCs	Others	Total
Yes	17	15	**32**
No	0	13	**13**
Total	**17**	**28**	**45**

Is Your Contingency Analysis Operational?	RCs	Others	Total
Yes	17	14	**31**
No	0	1	**1**
Total	**17**	**15**	**32**

Table 2.6-2 — Prevalence of Operational Applications

The 1 respondent who reports a non-operational contingency analysis application indicates there are plans to make it operational.

Perceived Value of Contingency Analysis Application

Most respondents perceive that contingency analysis is the most critical tool for secure system operation and is ”essential” for operating the system reliably after a disturbance. Table 2.6-3 summarizes the values respondents assign to contingency analysis.

How Valuable is Contingency Analysis?	RCs	Others	Total
Is contingency analysis essential?	16	13	**29**
Is contingency analysis desirable?	1	1	**2**
Is contingency analysis of minimal value?	0	0	**0**
Is contingency analysis of no value?	0	0	**0**
Total	**17**	**14**	**31**

Table 2.6-3 — Perceived Value of Contingency Analysis

Characteristics of Applications

Respondents were asked to describe the general characteristics of their contingency analysis applications. The questions in this section of the survey cover the integration of contingency analysis within EMSs, interfaces between contingency analysis and the state estimator, and algorithms used in the applications. Table 2.6-4 summarizes respondents' reported customization of contingency analysis applications. Table 2.6-5 describes the integration of contingency analysis with EMS systems. Table 2.6-6 describes the algorithms used in respondents' contingency analysis applications.

Degree of Contingency Analysis Customization	RCs	Others	Total
Off-the-shelf with some customization	9	6	**15**
Off-the-shelf	5	5	**10**
Highly customized	3	3	**6**
Total	**17**	**14**	**31**

Table 2.6-4 — Customization of Applications

Degree of Contingency Analysis Integration	RC	Other	Total
Fully integrated with production SCADA/EMS system	16	14	**30**
Interfaced to SCADA/EMS system	1	0	**1**
Stand-alone	0	0	**0**
Total	**17**	**14**	**31**

Table 2.6-5 — Integration of Contingency Analysis

Table 2.6-5 indicates that the contingency analysis applications of 97 percent of all respondents (30 out of 31) are integrated fully with their EMS systems. This result highlights the prevalence of contingency analysis as a real-time application.

Contingency Analysis Algorithm	RCs	Others	Total
Full AC	9	8	**17**
Decoupled	8	4	**12**
Other	0	2	**2**
Total	**17**	**14**	**31**

Table 2.6-6 — Contingency Analysis Algorithms

All respondents indicate that their contingency analysis uses the state estimator solution as a base case, which again implies the widespread use of contingency analysis as a real-time tool for predicting post-contingency system conditions.

Modeling Power Controls

Respondents were asked how their applications, when simulating contingencies, model power controls, both reactive (transformer taps, generators, and capacitors) and active (loads, generators, and phase shifters). Table 2.6-7 summarizes the modeling of internal load tap changer (LTC) taps during contingency analysis. Table 2.6-8 summarizes the modeling of shunt-series reactive devices during simulations.

Modeling LTC Taps in Contingency Analysis (Internal)	RCs	Others	Total
Locked globally	11	5	**16**
Can be moved for specific contingencies	1	4	**5**
Can be moved for specific LTCs	2	0	**2**
Globally free to move	1	3	**4**
Other(s)	2	2	**4**
Total	**17**	**14**	**31**

Table 2.6-7 — LTC Modeling in Contingency Analysis

Modeling Shunt/Series Reactive Devices in Contingency Analysis (Internal)	RC	Other	Total

Other(s)	1	0	**1**
Total	**17**	**14**	**31**

Table 2.6-8 — Modeling Shunt/Series Devices

Although no respondents report that they relax generator Mvar limits when modeling specific contingencies, 14 percent (4 out of 29) relax them for specific generators. Regarding active power controls, only 33 percent of respondents (10 out of 30) have applications that incorporate load change-over capability (the capability to transfer lost load to other specific loads). Seventy-three percent of respondents (22 out of 30), however, indicate that their applications can reallocate lost load and generation using generation participation factors. Tables 2.6-9 and 2.6-10 summarize capabilities related to active power control.

Do You Have Automatic Load Change-Over Capability?	RCs	Others	Total
Yes	6	4	**10**

Table 2.6-10 — Reallocation of Generation and Load

Most respondents (22 out of 30) reallocate lost generation and load using a single set of generation participation factors.

Actions Indicated by Applications

Respondents report that they model various remedial control actions in their contingency analysis applications. Most survey participants model LTCs, shunt reactive devices, and generators as remedial controls; however, 1 respondent uses RASs that require rigorous modeling. Table 2.6-11 summarizes the inclusion of post-contingency manual actions in contingency definitions. Table 2.6-12 summarizes the various remedial controls that respondents model.

Defining Contingencies

Contingencies can be defined based on the voltage levels of the elements involved. The minimum voltage level for elements included in contingency analysis usually depends on the structure of the region's transmission system. Survey respondents were asked what minimum voltage level they use in modeling contingencies. Fifty-three percent of all respondents (15 out of 28) monitor internal facilities having voltages less than 69 kV, and 82 percent (23 out of 28) monitor internal facilities having voltages less than 115 kV. These data indicate that most entities monitor lower-voltage facilities.

Responses indicate that RCs designate an average minimum voltage level of 105 kV although 1 RC models only those contingent elements that exceed 315 kV. Figure 2.6-1 shows the distribution of minimum kV levels of contingent elements that RCs and other respondents model.

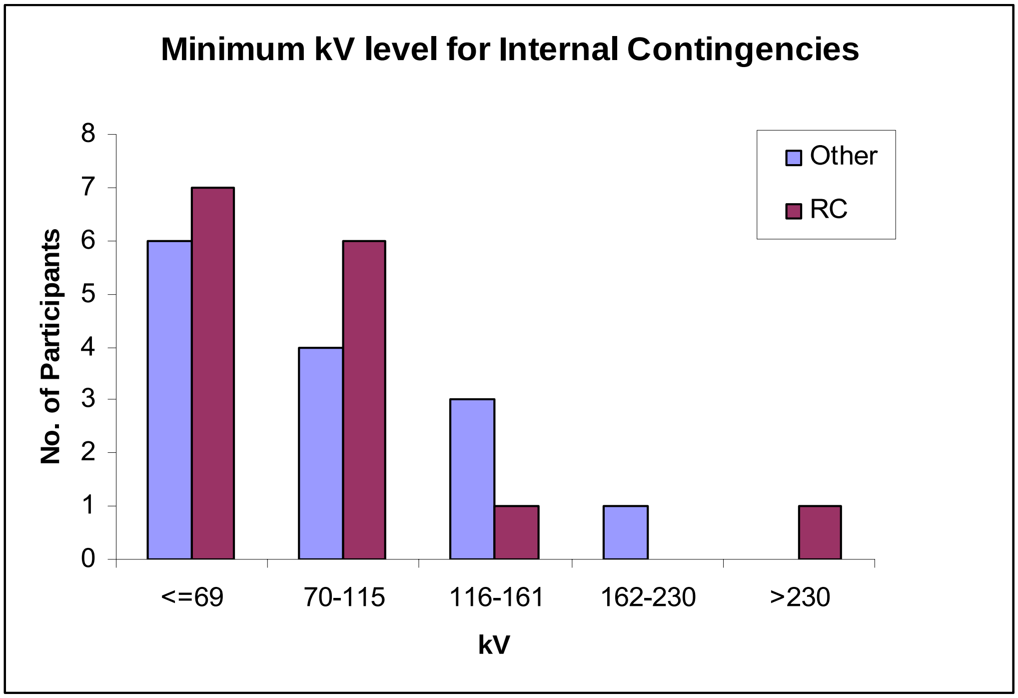

Figure 2.6-1 — Minimum kV Level for Modeled Contingencies

Figure 2.6-1 shows that 45 percent of respondents (13 out of 29) model contingencies that are less than 69 kV, and 35 percent (10 out of 29) model contingencies that have a minimum voltage between 70 and 115 kV. These data indicate that most entities consider the effects of outages of low-voltage transmission system elements although the practice varies greatly by region.

Seventy percent of all respondents (21 out of 30) define as contingencies all or most internal facilities that exceed the designated minimum kV levels. Only 23 percent of respondents (7 out of 30), however, define as contingencies all or most external facilities that affect internal systems. Table 2.6-13 summarizes reported practices regarding defining internal and external contingencies.

What Describes Your Contingency Definitions above Minimum kV Level?	RCs	Others	Total
All/most internal facilities are defined	10	11	**21**
Only select/critical internal facilities are defined	6	3	**9**
All/most external facilities that impact internal system are defined	7	0	**7**
Only select/critical external facilities that impact internal system are defined	4	9	**13**
No external contingencies are defined	5	5	**10**
Total	**16**	**14**	**30**

Table 2.6-13 — Contingency Definitions

An unexpectedly high 33 percent of respondents (10 out of 30) define no external contingencies. This result indicates a need to establish requirements for defining both external contingencies that affect internal systems and internal contingencies that could affect neighboring systems. This issue is addressed in the Recommendations for New Reliability Standards section below.

Survey responses define a range of transmission elements as contingencies. Exactly 60 percent of respondents (18 out of 30) categorize both circuit breakers and other transmission equipment as contingencies. Table 2.6-14 summarizes the elements respondents define as contingencies.

What Do You Define as Contingencies?	RC	Other	Total
Individual circuit breakers	9	10	**19**
Transmission lines	16	13	**29**
Transformers	16	12	**28**
Generating units	14	11	**25**
Bus faults	5	4	**9**
Phase-shifters (Phase angle regulators)	7	3	**10**
Loads	6	3	**9**
Shunt capacitors/reactors	5	1	**6**
Static var compensators	2	0	**2**
FACTS devices	0	0	**0**
DC lines (pole failures)	3	2	**5**
Multiple lines (on shared structure or right-of-way)	11	4	**15**
Other(s)	1	1	**2**
Total	**16**	**14**	**30**

Table 2.6-14 — Contingency Elements

Based on Table 2.6-14, contingencies most commonly comprise transmission lines and transformers. Individual circuit breakers also may be included in modeling contingencies, depending on the system configuration.

The total number of contingencies each respondent defines ranges from 30 to 10,000, as shown in Table 2.6-15. Figure 2.6-2 shows the ratio of total contingencies defined to the number of transmission lines and transformers each respondent models.[63]

Respondent	Total Contingencies	Respondent	Total Contingencies
R01	30	R17	900
R02	50	R18	973
R03	70	R19	1,000
R04	106	R20	1,000
R05	118	R21	1,500
R06	300	R22	1,500
R07	300	R23	1,800
R08	358	R24	3,000
R09	400	R25	3,500
R10	400	R26	4,340
R11	550	R27	10,000
R12	568	Average	1,324
R13	600	Median	800
R14	800	Minimum	30
R15	800	Maximum	10,000
R16	800		

Table 2.6-15 — Number of Contingencies Defined

63 Aliases are used for responses from RCs and TOPs to mask respondents' names. The aliases in this table are not necessarily consistent with those used in similar tables or figures in this report. That is, "R01" in any given table or figure is not the same as "R01" or the equivalent identifier in another table or figure in this report.

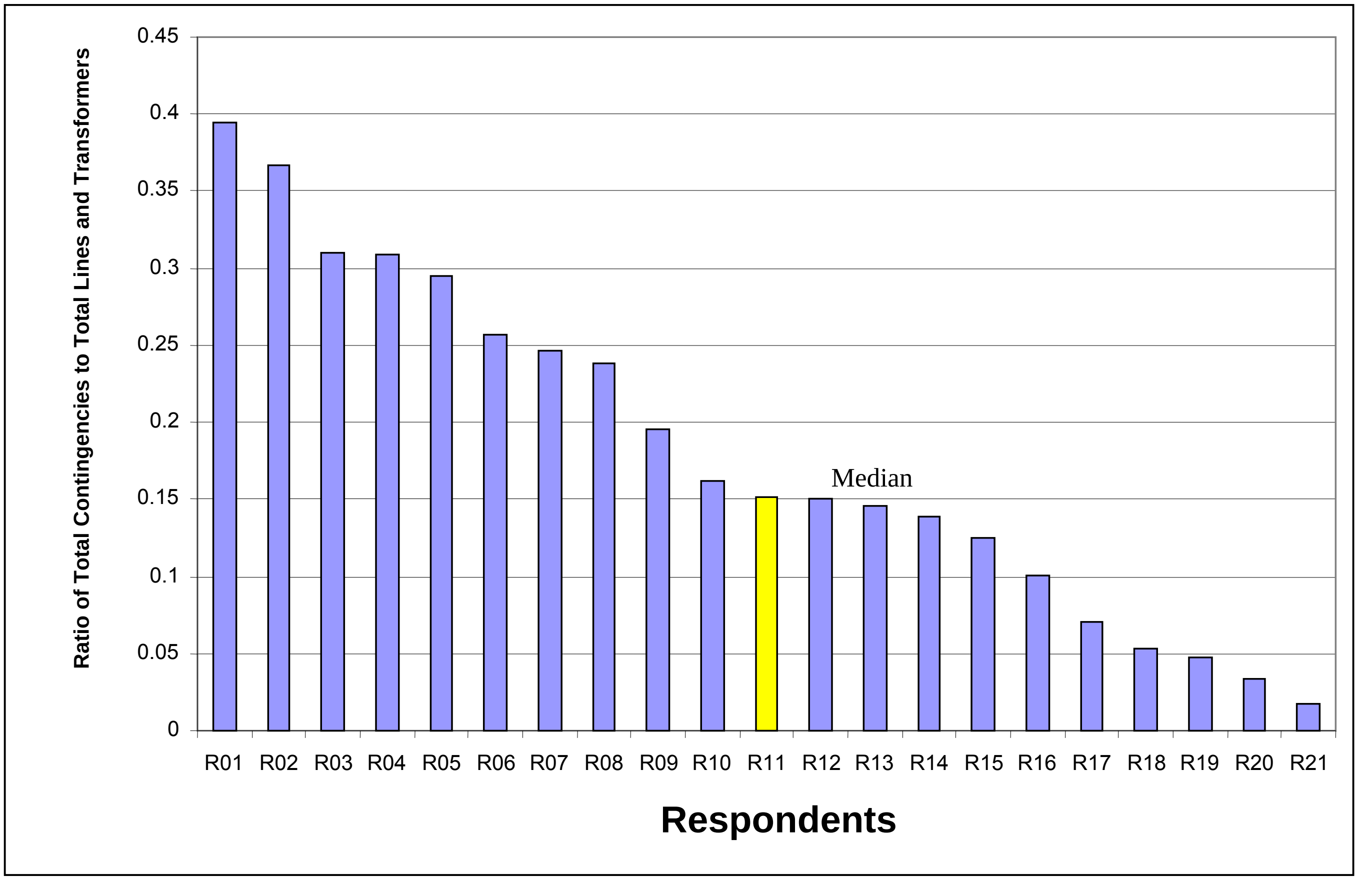

Figure 2.6-2 — Ratio of Total Contingencies to Total Branches and Transformers

Monitoring Limit Violations

The primary purpose of contingency analysis is to identify limit violations on monitored transmission system elements resulting from the post-contingency effects of the outages of transmission system elements modeled as contingent elements. Most RCs, TOPs, and BAs monitor selected elements, ignoring violations on any elements they do not monitor. Monitored elements are classified primarily by kV level. The minimum kV level for which internal system monitoring is applied is 24 kV. Figure 2.6-3 summarizes the minimum kV levels of transmission system elements that RCs and others monitor.

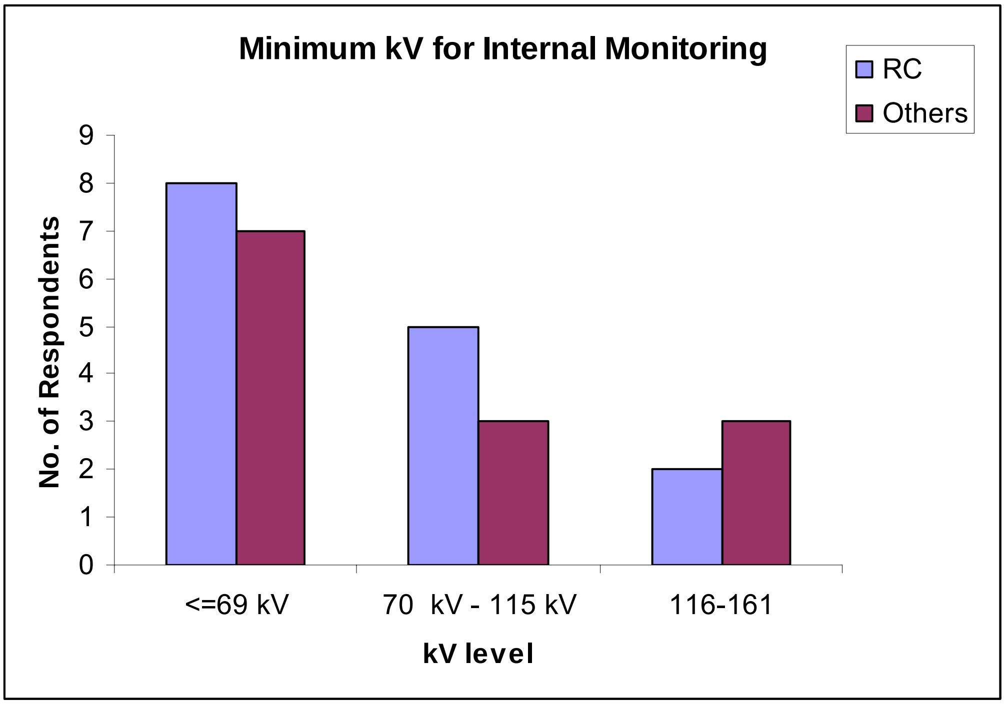

Figure 2.6.3 — Minimum kV Level Monitored

Figure 2.6-3 shows that 53 percent of all respondents (15 out of 28) monitor internal facilities having voltages less than 69 kV, and 82 percent (23 out of 28) monitor those having voltages less than 115 kV. These data indicate that most entities monitor lower-voltage facilities above their specified minimum kV level. However, few respondents also monitor all or most external facilities that affect their own system. Table 2.6-16 summarizes respondents' approaches to monitoring internal and external facilities.

What Best Describes Your Internal and External Monitored Facilities?	RCs	Others	Total
All/most internal facilities are monitored	13	11	**24**
Only selected/critical internal facilities are monitored	2	3	**5**
Total	14	15	**29**
All/most external facilities that impact internal system are monitored	7	0	**7**
Only selected/critical external facilities that impact internal system are monitored	6	8	**14**
No external facilities are monitored	3	6	**9**
Total	**16**	**14**	**30**

Table 2.6-16 — Internal and External Facilities Monitored

Only 23 percent of respondents (7 out of 30) monitor all relevant external facilities, and 30 percent (9 out of 30) monitor none. The data in Table 2.6-16 highlight the lack of wide-area monitoring.

As shown in Table 2.6-17, the total number of facilities each respondent monitors ranges from 35 to 10,000. The number of facilities monitored depends on the size of the network model used in the contingency analysis application.

Respondent	Total Monitored Facilities	Respondent	Total Monitored Facilities
R01	10,000	R13	750
R02	9,243	R14	500
R03	8,000	R15	500
R04	7,000	R16	487
R05	5,000	R17	254
R06	4,000	R18	212
R07	3,000	R19	118
R08	2,700	R20	35
R09	2,400	Average	2,946
R10	1,800	Median	1,675
R11	1,550	Minimum	35
R12	1,371	Maximum	10,000

Table 2.6-17 — Total Number of Facilities Monitored

Signaling Violations

Most respondents indicate that they can monitor thermal, low-voltage, and high-voltage violations; some (53 percent) can also monitor violations in bus voltage drop. Approximately 73 percent of all respondents employ some sort of alarm signal to alert them to contingency violations. Table 2.6-18 describes respondents' practices for signaling contingency violations.

Which Best Describes How You Alarm Violations?	RCs	Others	Total
General alarms — details viewed on contingency analysis displays	4	5	**9**
Detailed alarms — include details of facility, contingency, and violations	7	6	**13**
Others	1	0	**1**
No alarms — violations viewed on contingency analysis displays	4	3	**7**
Total	**16**	**14**	**30**

Table 2.6-18 — Signaling Contingency Violations

Contingency analysis applications typically can identify unsolved or diverged contingencies. Such contingencies are of special concern because they can indicate impending reliability problems. Sixty percent of respondents (18 out of 30) indicate that an alarm is used to signal unsolved contingencies. Only 38 percent (11 out of 29), however, state that their operators have tools or procedures to detect whether a failed contingency indicates a potential voltage collapse.

Contingency analysis also can warn operators of impending violations. Table 2.6-19 summarizes the methods respondents report using to warn operators of impending violations.

Which best Describes How Operators Are Notified of Approaching Violations?	RCs	Others	Total
Warning prior to actual violation level	10	10	**20**
No warning prior to actual violation level	5	3	**8**
Others	1	1	**2**
Total	**16**	**14**	**30**

Table 2.6-19 — Signaling Impending Violations

Approximately 70 percent of respondents (14 out of 20) indicate that operators can select the level at which an alarm will alert them of impending violations.

Application Features

Respondents were asked to describe the features of their contingency analysis applications. A key feature is how the application presents its results to system operators. Because there may be numerous defined contingencies (depending on system size), it is important that violations be categorized. Seventy-one percent of total respondents (22 out of 31) indicate that their application has a feature for categorizing violations, and all of them make use of this feature. Seventy-three percent of RCs (11 out of 15) and 68 percent of all respondents (15 out of 22) consider this feature "essential." Table 2.6-20 summarizes the criteria used to categorize violations.

What Criteria Could the Operator Use/Apply to Automatically Sort Violations?	RCs	Others	Total
Violations sorted by type	12	4	**16**
Violations sorted by severity	14	6	**20**
Violations sorted by ownership and/or geographic area	5	1	**6**
Violations sorted by contingency	7	3	**10**
As needed	1	1	**2**
Other(s)	3	1	**4**
Total	**16**	**6**	**22**

Table 2.6-20 — Criteria for Categorizing Violations

Survey respondents also were asked how violations are presented to operators. Tables 2.6-21 and 2.6-22 show the prevalence of color coding and/or graphical displays as techniques for visualization of violations.

Are Violations Color-Coded?	RCs	Others	Total
Yes	7	2	**9**
No	9	4	**13**
Total	**16**	**6**	**22**

Table 2.6-21 — Are Violations Color Coded?

Do You Have the Ability to View Graphical Displays to Determine Violation Severity?	RCs	Others	Total
Yes	8	1	**9**
No	8	5	**13**
Total	**16**	**6**	**22**

Table 2.6-22 — Can Violations Be Viewed Graphically?

Contingency analysis applications can be used to perform theoretical or study analyses of potential problems. The study analysis usually establishes a power-flow case representing anticipated future conditions (i.e., the time of today's forecasted peak load) and then performs "what-if" studies upon this base case (i.e., what if any defined contingency occurred during peak load conditions). All respondents report that their contingency analysis application has a study feature and that they use this feature. Table 2.6-23 summarizes respondents' perceived value of the study feature.

How do You Rank the Value of Study Contingency Analysis to Situational Awareness?	RCs	Others	Total
Essential	14	12	**26**
Desirable	3	2	**5**
Minimal	0	0	**0**
No value	0	0	**0**
Total	**17**	**14**	**31**

Table 2.6-23 — Perceived Value of Study Contingency Analysis

An important feature of contingency analysis applications is the ability to group and prioritize contingencies and monitored elements. This feature enables operators to easily enable/disable monitoring of sets of monitored elements and activate/deactivate sets of contingencies that have common features (i.e., that are at the same kV level) without having to control each one individually. Eighty-one percent of all respondents (25 out of 31) report having features that group and prioritize contingencies and monitored elements, and 45 percent (10 out of 22) consider those features "essential."

Respondents were asked whether their applications are able to identify the worst (most harmful) contingency impacting each monitored facility. Responses are presented in Table 2.6-24. Approximately half of all respondents consider this feature "essential."

Do You Have the Ability to Automatically Detect the Worst Contingency for Each Monitored Facility?	RCs	Others	Total
Yes	10	6	**16**
No	7	8	**15**
Total	**17**	**14**	**31**

Table 2.6-24 — Automatically Detecting the Worst Contingency

Some contingency analysis applications can calculate distribution factors (line outage distribution factors, generation shift factors, etc.) that can be used to identify remedial control actions such as re-configuration and re-dispatch or to trigger operating guides to help with resolving potential violations of operating limits. The contingency analysis applications of only 23 percent of respondents (7 out of 31) contain this feature.

Rate of Execution

Most respondents rely on periodic triggers to initiate a contingency analysis. The rate at which contingency analyses are executed ranges from once every minute to once every 30 minutes, with an average of once every 8 minutes reported by RCs and once every 13 minutes reported by TOPs. Figure 2.6-4 shows the rate at which RCs and others execute contingency analyses.

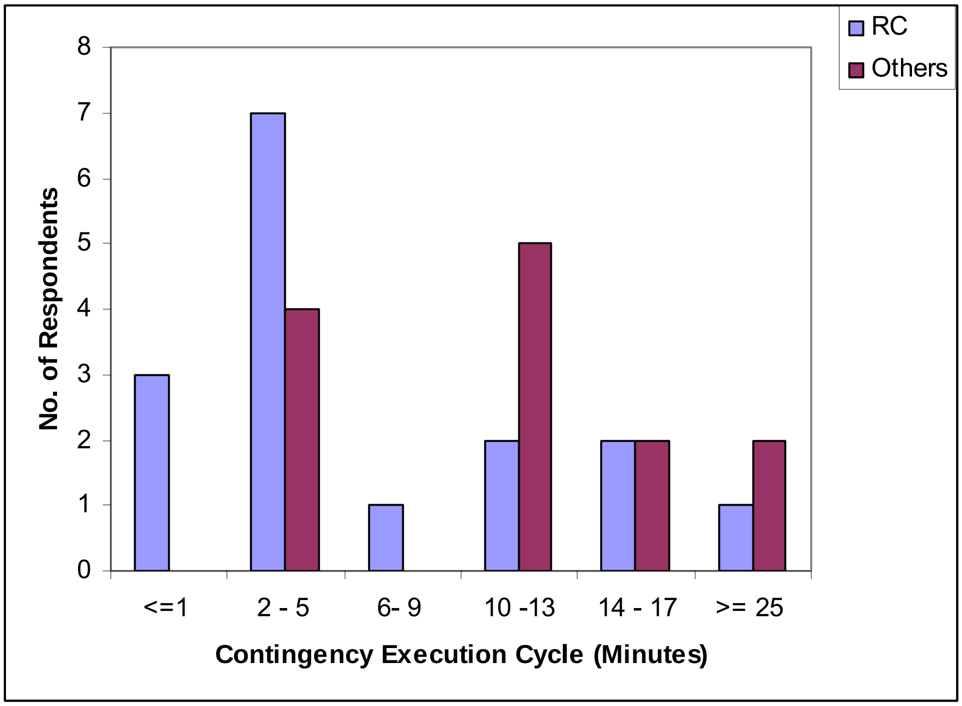

Figure 2.6-4 — Execution Rate for Contingency Analysis

The most common execution frequency is every 5 minutes. Some respondents use a manual trigger or disturbance triggers to augment routine periodic execution. The maximum time required for any RCs contingency analysis to execute is 4 minutes, with an average execution time of less than 1.5 minutes.

Availability of Contingency Analysis Application

The availability of the contingency analysis application is generally measured by how often it produces a successful solution for a given number of executions. Only 27 percent of respondents (8 out of 30) have historical data on contingency solutions or metrics for measuring their application's robustness. Table 2.6-25 summarizes the value respondents assign to being able to measure the availability of their contingency analysis applications.

How Would You Rank the Value of Having Capabilities in Contingency Analysis to Provide Availability Data?	RCs	Others	Total
Desirable	5	7	**12**
Minimal	5	3	**8**
None	1	1	**2**
Total	**11**	**11**	**22**

Table 2.6-25 — Perceived Value of Availability Data

A rather high 36 percent of respondents (8 out of 22) consider the ability to collect reliability data in contingency analysis to be of minimal value. In contrast, all who have tools to measure availability are using them. Respondents were asked approximately how often and how long their contingency analysis application is unavailable (the frequency distribution of down time). Of the 6 respondents who answered this question, most note that their answers rely on estimates rather than historical data. Five of those 6 respondents indicate that, of all the times that contingency analysis becomes unavailable, it is unavailable for less than 15 minutes for at least 95 percent of those times. Four of those respondents report that it is never unavailable for longer than 15 minutes.

Support for Applications

Because most respondents consider contingency analysis critical to real-time operation of their system, they understand the need to monitor the application's availability and functionality. Approximately 61 percent of respondents (19 out of 31) report having tools or procedures for monitoring the status of their contingency analysis application and making support personnel aware when it is unavailable or functioning incorrectly. Table 2.6-26 summarizes the availability of tools and procedures for monitoring the status of the contingency analysis application. Table 2.6-27 summarizes the perceived value of those tools and procedures.

Do You Have Tools or Procedures to Monitor the Status of Your Contingency Analysis?	RCs	Others	Total
Yes	12	7	**19**
No	5	7	**12**
Total	**17**	**14**	**31**

Table 2.6-26 —Tools/Procedures to Monitor Contingency Analysis Application's Status

How Would You Rank the Value of Having Tools to Monitor the Status of Your Contingency Analysis?	RCs	Others	Total
Desirable	4	7	**11**
Minimal	1	0	**1**
None	0	0	**0**
Total	**5**	**7**	**12**

Table 2.6-27 — Perceived Value of Monitoring Tools for Contingency Analysis Status

Approximately 94 percent of all respondents (17 out of 18), including all responding RCs, say that their contingency analysis is monitored continuously 24 hours per day, 365 days per year.

Recommendations for New Reliability Standards

The results of the Real-Time Tools Survey detailed in the previous section support the assertion of Macedo (2004)[64] that contingency analysis is a minimum requirement -- i.e., an essential tool for operators.

Recommendation – S1

Mandate the following reliability tools as mandatory monitoring and analysis tools

- Alarm Tools
- Telemetry Data Systems
- Network Topology Processor
- State Estimator
- Contingency Analysis

Contingency Analysis: Mandatory Monitoring and Analysis Tool

The survey results indicate that contingency analysis applications are inherently delivered as part of commercially available modern SCADA/EMS systems. RTBPTF considers contingency analysis an essential tool for enabling operators to monitor and maintain the reliability of the bulk electric system. Because contingency analysis is required for maintaining an "n-1" secure bulk power transmission system, RTBPTF places it in the Reliability Toolbox among the mandatory monitoring and analysis tools[65]. Existing NERC reliability standards implicitly assume the use of contingency analysis to aid RCs and TOPs in maintaining situational awareness for the bulk electricity system. Standard IRO-

[64] Macedo, Frank. 2004. *Reliability Software: Minimum requirements and Best practices*. FERC Technical Conference. July 14. http://www.ferc.gov/EventCalendar/Files/20040716092511-20040714085315-FrankMacedo.pps
[65] See the Reliability Toolbox Rationale and Recommendation section.

002 (Requirement R7) states "[e]ach Reliability Coordinator shall have ***adequate analysis tools*** [emphasis added] such as state estimation, ***pre and post-contingency analysis*** [emphasis added] capabilities (thermal, stability, and voltage), and wide area overview displays." Specifying that contingency analysis as part of the mandatory Reliability Toolbox clarifies that, under current NERC reliability standards, contingency analysis, as defined, is required. It also clarifies the term "adequate analysis tools."

Availability of Contingency Analysis Application

Given that contingency analysis is deemed a mandatory tool for maintaining situational awareness of the bulk electric system, it must be highly available and redundant. The availability of the contingency analysis application is discussed in the recommendations for Section 5.4, Critical Applications Monitoring. However, RTBPTF believes that a more complete understanding than that described in Section 5.4 is necessary. In particular, a metric for measuring adequate availability should be established.

Recommendation – S12

Specify and measure minimum availability for contingency analysis, including a requirement for solution quality.

RTBPTF Recommendation

RTBPTF developed the following proposed requirement (PR) for Standard TOP-006 in order to specify a minimum availability for contingency analysis.

PR1. Availability of Contingency Analysis

PR1.1 Real-Time Contingency Analysis Availability Metric 1 (RTCAA1): Each Reliability Coordinator and Transmission Operator shall ensure that its real-time Contingency Analysis produces at least one converged base-case solution and processes all defined contingencies for at least 97.5 percent of all10-minute clock periods (6 non-overlapping periods per hour) during each calendar month.

PR1.2 Real-Time Contingency Analysis Availability Metric 2 (RTCAA2): Each Reliability Coordinator and Transmission Operator shall also ensure that its real-time Contingency Analysis produces at least one converged base-case solution and processes all defined contingencies for every continuous 30-minute interval during a calendar day.

RTBPTF developed the following proposed measures (PMs) for the requirements given above. RTBPTF recommends that a pilot program (or field trial) be conducted to validate the effectiveness of the following PMs.

PM1. Measures for Availability of Contingency Analysis

PM1.1 Each Reliability Coordinator and Transmission Operator shall achieve, as a minimum, Requirement PR1.1 (RTCAA1) compliance of 97.5 percent. RTCAA1 is calculated by converting a Contingency Analysis availability ratio to a compliance percentage, as follows:

$$RTCAA1 = \left[1 - \frac{V_{month}}{TP_{month}}\right] * 100$$

$where:$

V_{month} = Violations per month

TP_{month} = Total Periods per month

The violations per month represent the number of 10-minute clock periods during which real-time Contingency Analysis did not produce at least one viable solution (one converged base-case solution and all defined contingencies processed).

PM1.2 Each Reliability Coordinator and Transmission Operator shall allow no RTCAA2 violations. One RTCAA2 violation equates to the real-time Contingency Analysis failing to produce at least one viable solution (one converged base-case solution and all defined contingencies processed) within any continuous 30-minute interval during a calendar day (three consecutive 10-minute clock periods). For example, if the real-time Contingency Analysis is unavailable continuously for 40 minutes (no viable solution within four consecutive 10-minute clock periods), RTCAA2 = 1 for the calendar day. If real-time contingency analysis is unavailable continuously for 60 minutes (no viable solution within six consecutive 10-minute clock periods), RTCAA2 = 2 for the calendar day. For simplicity, when the real-time Contingency Analysis is unavailable during a period that spans midnight, the RTCAA2 calculation shall be attributed to the preceding calendar day.

Rationale

Contingency analysis is a critical application for identifying potential IROL/SOL violations. Recommended requirement PR1.1 is consistent with the NERC mandate that MISO fully implement and test its state estimator and contingency analysis tools "to ensure they can operate reliably no less than every ten minutes."[66] Proposed requirement PR1.2 specifies that the real-time contingency analysis must be unavailable for no more than 30 minutes during a calendar day so that situational awareness is not compromised.

RTBPTF believes that these proposed availability requirements are consistent with requirements that operators remain aware of potential IROL/SOL violations and take the actions necessary to alleviate violations as soon as possible but always within 30 minutes. In addition, these recommended metrics are consistent, performance based, and, based on survey findings, technically feasible.

Quality of Solutions

Contingency analysis solves a single power-flow problem for each defined contingency. If the power-flow solution for a particular contingency fails to converge, it could mean that a reliability problem such as a voltage collapse might occur if the contingent event actually happened. In contrast, failure of a contingency to solve could indicate that a modeling error or other problem is degrading the quality of the base case and thus the results for all contingencies, even those that solve successfully. It is important to examine unsolved or diverged contingencies to assess whether the power-flow failure may indicate an impending problem. The survey indicates that 60 percent of all respondents consider failed contingencies important enough that audible alarms bring the failures to the operators' attention. RTBPTF shares this concern and believes that failed (unsolved) contingencies represent a key indicator of the quality of contingency analysis solutions.

RTBPTF Recommendations

RTBPTF developed the following proposed requirements (PRs) for Standard TOP-006 to ensure the quality of contingency analysis solutions.

PR2. Quality of Contingency Analysis Solutions

PR2.1 Each Reliability Coordinator and Transmission Operator shall have documented procedures for investigating and resolving the failure of a contingency to solve.

PR2.2 Each Reliability Coordinator and Transmission Operator shall have processes for recording (logging) all contingencies that fail

---

[66] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April. p. 152.

to solve. Each log entry shall include a contingency identifier and the date/time of the solution failure.

PR2.3 Each Reliability Coordinator and Transmission Operator shall document the actions taken to resolve a failed contingency.

To validate the effectiveness of these requirements, RTBPTF proposes that they be included in the pilot program (or field trial) previously recommended for the availability metrics. RTBPTF developed the following proposed measures (PMs) for the requirements given directly above.

PM2. Measures for Quality of Contingency Analysis Solutions

PM2.1 Each Reliability Coordinator and Transmission Operator shall demonstrate that operators have ready access to current, approved procedures for investigating contingency failures.

PM2.2 Each Reliability Coordinator and Transmission Operator shall provide, if requested, hard copies of contingency failure logs for specified time periods.

PM2.3 Each Reliability Coordinator and Transmission Operator shall provide, if requested, records of the actions taken to resolve specified failed contingencies.

Rationale

Failure of a contingency to solve can indicate a poor-quality base-case solution or a problem with the system state such as a voltage collapse. In either case, situational awareness of potential IROL or SOL violations is compromised until personnel can identify and resolve the cause of the failed contingency. Enacted along with the recommended availability metrics, the above recommendations will provide that this critical real-time tool receives the attention and maintenance required to consistently produce solutions of sufficient quality for its intended purpose.

Criteria for Defining Contingency

The primary function of contingency analysis is to provide an early indication of an impending limit violation resulting from the outage of a transmission element. Thus, criteria are needed to identify which elements of the bulk electric system must be defined as contingencies. Requirement R1 of Standard IRO-003-1 states:

> Each Reliability Coordinator shall monitor all Bulk Electric System facilities, which may include sub-transmission information, within its Reliability Coordinator Area and adjacent Reliability Coordinator Areas, as

> necessary to ensure that, ***at any time, regardless of prior planned or unplanned events*** [emphasis added], the Reliability Coordinator is able to determine any potential System Operating Limit and Interconnection Reliability Operating Limit violations within its Reliability Coordinator Area.

This requirement provides the criteria that define which facilities are to be monitored within the RC's area, but does not specify that RCs are to define all those facilities as contingencies. The emphasized words imply, however, that all possible contingent events must be analyzed in real time in order to maintain, under any possible topological configuration, the capability to identify potential IROL and SOL violations.

Real-time contingencies must be defined that accurately reproduce the results of activated protective relays, which are installed to remove elements from service to minimize damage or stop the spread of undesirable system conditions. Because in some cases more than one element may be removed, it is insufficient to define a real-time contingency as only a single element. A contingency must be defined as the set of circuit breakers or other automatic devices that operate to clear a fault or otherwise respond to protective relay actions intended to remove an element from service.[67]

Consider, for example, two transmission lines connected in a breaker-and-a-half scheme,[68] as shown in Figure 2.6-6. If the breaker between line B and bus 2 were open for maintenance, a fault on line A would trip the remaining two breakers, thereby removing both line A and B from service. If the contingency for the loss of line A was defined simply as the loss of line A, and not the tripping of the breakers connecting the line to the grid, then a real-time contingency analysis would not evaluate the true result of the event.

[67] RTBPTF is not recommending that contingencies be defined that represent relay mis-operations or over-trips.

[68] A breaker-and-a-half bus scheme is a "method of interconnecting several circuits and breakers in a switchyard so that three circuit breakers can provide dual switching to each of two circuits by having the circuits share one of the breakers, thus a breaker and one-half per circuit; this scheme provides reliability and operating flexibility." From the Bonneville Power Administration web site: http://www.bpa.gov/corporate/pubs/definitions/b.cfm - busscheme

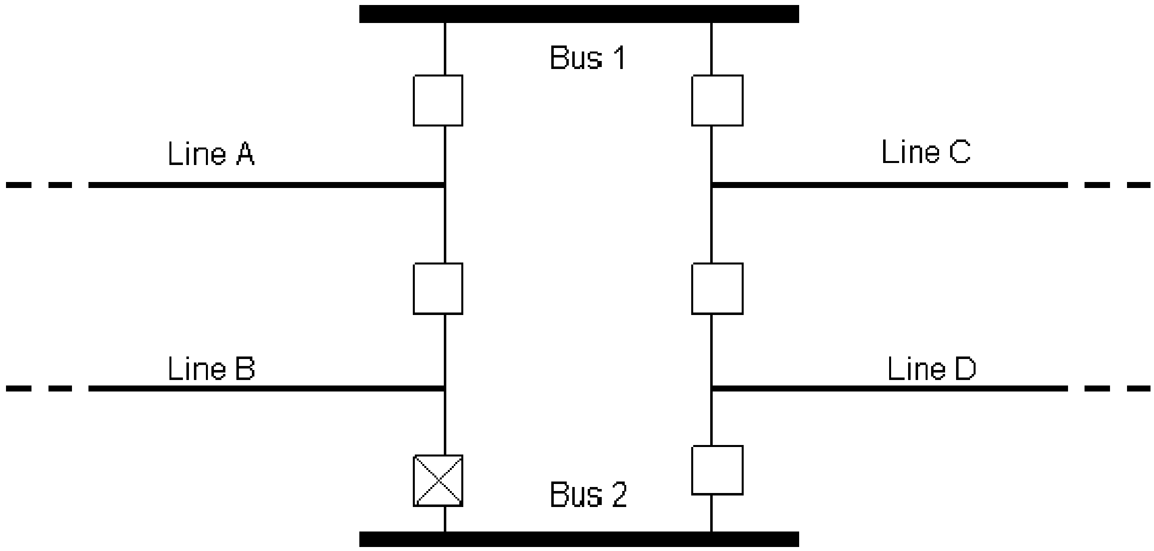

Figure 2.6-6 — Breaker-and-a-Half Scheme

Recommendation – S13

Specify criteria and develop measures for defining contingencies.

RTBPTF Recommendation

RTBPTF developed the following proposed requirements (PRs) for Standard TOP-006 to specify the criteria for defining contingencies that must be analyzed in real time.

PR3. Criteria for Defining Contingencies

PR3.1 Each Reliability Coordinator and Transmission Operator shall define as a contingency to be analyzed in real time each element of the Bulk Electric System[69] within its area of responsibility.

PR3.2 Each Reliability Coordinator and Transmission Operator shall define as contingencies to be analyzed in real time all critical Bulk Electric System elements in adjacent areas that, if taken out of service ***at any time, regardless of prior planned or unplanned events,*** could cause an IROL or SOL violation.

PR3.3 Each contingency must be defined to include the set of circuit breakers or other automatic devices designed to clear a fault or

[69] This recommendation assumes a rational and comprehensive definition of the bulk electric system. See the discussion of the bulk electric system in the Introduction of this report.

otherwise operate in response to activation of protective relays to remove the Bulk Electric System element from service.

RTBPTF developed the following proposed measures (PMs) for the requirements given directly above.

PM3. Measures for Defining Contingency

PM3.1 Each Reliability Coordinator and Transmission Operator shall have a list of the contingencies in its area of responsibility that are analyzed in real-time Contingency Analysis and shall document the criteria used to define as contingencies Bulk Electric System elements in its area of responsibility.

PM3.2 Each Reliability Coordinator and Transmission Operator shall have a list of contingencies in adjacent areas that are analyzed in real-time Contingency Analysis and shall document the criteria used to define as contingencies Bulk Electric System elements in adjacent areas.

PM3.3 Upon request, each Reliability Coordinator and Transmission Operator shall demonstrate for a randomly designated set of contingencies how the contingency definitions accurately simulate the results of a protective relay being activated.

Rationale

The recommended requirement that RCs and TOPs define as contingencies all bulk electric system elements in their areas of responsibility is based on RTBPTF's interpretation of requirement R1 of Standard IRO-003. If impact-based reliability criteria are used to identify bulk electric system elements, then by definition each of those elements potentially can impact reliability. If "bright-line" criteria such as voltage or MW levels are used to identify bulk electric system elements, such criteria are proxies for impact-based criteria, and the bulk electric system elements so identified also, by definition, have potential impacts on reliability. Either way, each bulk electric system element must be defined as a contingency, and the potential impact of each bulk electric system element must be analyzed in real-time contingency analysis.

As discussed above for the breaker-and-a-half scheme, contingencies must be defined in sufficient detail so that the most realistic scenarios are analyzed, thus providing operators with the most realistic system impacts. Events that activate protective relays are the most common causes of the next contingency. To assess the full effects of a contingency, the contingency definition must include the specific devices that operate in response to activation of the protective relay that removes a bulk electric system element from service.

Applicability Statement for Recommended Standards

RTBPTF recommends that all RCs and TOPs be required to have contingency analysis for monitoring all elements of their bulk electric system, as detailed in the recommended additions or modifications to NERC standards. Other responsible entities who use contingency analysis to support or complement their RCs' ability to operate the bulk electric system in accordance with formal agreements, contracts, or established practices shall be subject to the same standards for contingency analysis as their reliability coordinators.

Recommendation – G5

Identify only existing controls modeled in contingency analysis and develop conservative contingency screening criteria.

Recommendations for New Operating Guidelines

RTBPTF developed the following proposed operating guidelines to support the recommended requirements and measures presented above.

- RCs and TOPs should confirm that their contingency analysis models only the controls that exist in the field. For example, contingency analysis should not be configured to change the modeled tap positions of fixed tap transformers during the analysis in order to solve a contingency or eliminate limit violations. If a control is automatic (i.e., its activation does not require operator intervention), it can be modeled in contingency analysis. Manually activated controls either should not be modeled, or, if they are modeled, results should be presented both with and without the controls. The rationale for this guideline is that if a control must be manually activated, the operator must be notified of the potential contingency that requires activating that control.
- If contingencies are screened before inclusion in analysis, RCs should apply conservative screening criteria, so that potentially harmful contingencies are not misidentified as harmless.

Areas Requiring More Analysis

RTBPTF is not recommending additional areas for analysis related to Contingency Analysis.

Examples of Excellence

The transmission network (grid) is the power source for the offsite power system. The trip of a nuclear power plant itself can affect the grid and result in a loss of offsite power (LOOP). The most common occurrence is reduction in plant's switchyard voltage as a result of loss of the nuclear plant. The low voltage at the plant can activate the voltage-protection system and remove the plant safety bus from offsite power. A real-time contingency analysis application can be used to simulate such conditions and alert plant operators in advance.

In addition, a generic letter from Nuclear Regulatory Commission (NRC) recommends usage of real-time contingency analysis to determine the grid conditions that would make the Nuclear Power Plant offsite power system inoperable in the event of various contingencies.[70] During the August 14, 2003 northeast blackout nine nuclear power plants tripped and eight of these lost offsite power. The length of offsite power unavailability ranged from 1 hour to six and one-half hours. Although nuclear power plants are designed to cope with a LOOP event through the use of onsite power supplies, LOOP events are considered precursors to station blackout. An increase in the frequency or duration of LOOP events increases the probability of core damage.

RTBPTF cites the use of real-time contingency analysis by Entergy Corporation to accurately simulate the effects of loss of nuclear power plant on switchyard voltage as an example of excellence (See EOE-9 in Appendix E).

Section 2.7
Critical Facility Loading Assessment

Definition

A critical facility loading assessment (CFLA) employs a computer application to evaluate a set of contingencies or other events that could affect reliability of the bulk electric system or one of its elements and then approximates the resultant post-contingency impacts for a pre-determined set of monitored elements. CFLA, which typically uses telemetered SCADA flows and line outage distribution factors (LODFs), represents an approximate, backup technique for obtaining a solution to contingency analysis if the primary state estimator and/or contingency analysis applications are unavailable.

Background

Macedo (2004)[71] cites use of CFLA as a best practice.

Summary of Findings

The CFLA section of the survey asks about use of CFLA applications for monitoring network conditions. Few Real-Time Tools Survey respondents report having a functional CFLA application. The applications that are in use appear to have wide ranges of capabilities and sophistication.

Of the 42 respondents to the CFLA question in the survey, only 4 RCs and 3 TOPs report having an application for performing CFLA. One RC gives no response. One RC that does not have CFLA ability plans to acquire the tool. Three TOPs also indicate they plan to acquire CFLA. Despite the low number of those who use CFLA, 6 out of the 7 respondents who have this application (all 4 RCs and 2 TOPs) rate it "essential" for situational awareness.

Features and Functions

Most of the respondents who report having CFLA use highly customized applications provided by their EMS vendors. Only 1 RC reports having developed an in-house CFLA application. All CFLA applications are either integrated or interfaced with the SCADA or the EMS; none operate in a stand-alone mode. Respondents' descriptions of their CFLA applications are presented in Table 2.7-1.

[71] Macedo, Frank. 2004. *Reliability Software Minimum Requirements & Best Practices*. FERC Technical Conference, July 14. Available at: http://www.ferc.gov/EventCalendar/Files/20040716092511-20040714085315-FrankMacedo.pps

NOTE: In the columns of the following table, the percentage value is preceded by the number of respondents out of the total that gave the indicated response. For example, “6/7 = 86%” means that 6 out of a total of 7 respondents, or 86% of respondents, gave the indicated response.

Which Best Describes Your CFLA?	All	RCs
Highly customized	6/7 = 86%	3/4 = 75%
Off-the-shelf with some customization	1/7 = 14%	1/4 = 25%
Off-the-shelf	0/7 = 0%	0/4 = 0%
Supplied by SCADA/EMS vendor	3/7 = 43%	3/4 = 75%
Supplied by other vendor	0/7 = 0%	0/4 = 0%
Developed in-house	4/7 = 57%	1/4 = 25%
Fully integrated with SCADA/EMS system	6/7 = 86%	3/4 = 75%
Interfaced to SCADA/EMS system	1/7 = 14%	1/4 = 25%
Stand-alone	0/7 = 0%	0/4 = 0%
Triggered periodically	5/7 = 71%	2/4 = 50%

Table 2.7-1 — Descriptions of CFLA Applications

Among the 4 RCs who have CFLA, only 2 have applications that can define contingencies in true topographical terms of breakers and equipment. The other applications define contingencies in terms of equipment only. All CFLA applications can define branch contingencies, and 3 out of 4 can also define generator contingencies. One RC reports that its application also defines unit and other types of contingencies.

CFLA software packages differ significantly in terms of sophistication. Some use externally calculated LODFs and/or generator shift factors to distribute SCADA flows or injections from contingent branches or generators to monitored branches. Such applications contain no internal topology processor. The CFLA applications that incorporate topology processors can provide more accurate results. Some respondents claim their applications are capable of approximating true post-contingency apparent power (MVA) loading, but most approximate only the resultant real power (MW) loading.

The applications of all 4 reliability coordinators who have CFLA incorporate the same ratings from SCADA as the primary contingency analysis uses. Three of the CFLA applications can monitor branches or multiple branch sets. These 3 can, at a minimum, also define the critical internal and external facilities that affect loads on internal system facilities.

Three of the applications run by RCs contain either general or detailed alarms for alerting users to violations, which can be categorized by severity. All 4 reliability coordinators consider this feature either “desirable” or “essential.”

Users

Respondents report that the system operators and control room staff are the primary users of CFLA applications.

Performance, Monitoring, and Availability

The rates at which CFLA applications execute vary. One RC's application executes on a 1-minute cycle while another's executes on a 4-second cycle, and those of the other 2 execute in response to changes in SCADA status data. The application of 1 TOP executes every 10 minutes, that of another every 30 seconds, and the last every 4 seconds. One RC says the program runs "full-time"; another indicates that the results from CFLA trigger other programs.

Survey results reveal that no RC has developed a metric for CFLA availability. Only 1 RC indicates that such a metric would be desirable.

Support for Application

Only 2 RCs monitor the availability of their CFLA applications continuously and notify on-call or dedicated support staff of any application failures.

Recommendations for New Reliability Standards

Based on results from the very few who responded to this section of the survey, RTBPTF does not recommend creating or modifying reliability standards or operating guidelines to incorporate tools for performing critical facility loading assessment. RTBPTF, however, recommends performing additional analysis of CFLA and similar approximate techniques to assess their value in providing a contingency solution if contingency analysis and/or state estimator applications are unavailable

Recommendations for New Operating Guidelines

RTBPTF does not recommend the development of new operating guidelines for Critical Facility Loading Limits.

Recommendation – A8

Evaluate capability of critical facility loading assessment application in providing a backup solution if contingency analysis or the state estimator is unavailable.

Areas Requiring More Analysis

RTBPTF recommends that CFLA and similar approximate techniques be evaluated for their value for providing backup solutions in the event that the state estimator or conventional contingency analysis applications become unavailable. For CFLA to serve in this manner as a useful backup tool, the anomalies that can cause contingency analysis to fail should not be a cause for CFLA to fail as well. The capability of CFLA to enhance the wide-area view and assist in providing security of the bulk electric system should be analyzed further, and the capabilities that are crucial to making CFLA a valuable tool should be identified and communicated to software providers. Improvements should also be made to include breaker-oriented topology along with equipment outages in CFLA contingency definitions in order to improve the accuracy of the estimation.

Examples of Excellence

RTBPTF cites the use of a Thermal Tracking CFLA by PJM to screen for transfer interface violations and a number of potentially serious double-contingency violations as an example of excellence (See EOE-10 in Appendix E).

Section 2.8
Power Flow

Definition

Power flow is a computer application used to calculate the state of the electric power system based on load, generation, net interchange, and facility status data. Power flow calculates the system state in the form of flows, voltages, and angles. Power flows are available in both online and offline versions.

An application that evaluates online power flow is typically incorporated into an EMS (or has a direct data feed from an EMS) and utilizes node-breaker topology, whereas offline power flow utilizes models of bus branches and static data. This section of the report pertains only to online power flow, which hereafter is referred to simply as "power flow."

Background

EMSs utilize various applications to monitor and analyze the condition of a power system. Applications such as the state estimator and contingency analysis are intended to run automatically at given intervals to provide operators with real-time situational awareness. Applications such as power flow and study contingency analysis, on the other hand, are used to assess system conditions for the next hour or day. Power flow also is used in "n-1" contingency analysis to simulate the effect of the next worst contingency. In addition, it is used to identify potential voltage collapse or reliability problems.

The *NERC Blackout Report* identified inadequate hour-ahead and day-ahead studies. The following excerpts from the document emphasize the importance of look-ahead analysis.[72]

> FirstEnergy did not perform adequate hour-ahead operations planning studies after Eastlake 5 tripped off-line at 13:31 to ensure that FirstEnergy could maintain a 30-minute response capability for the next contingency. The FirstEnergy system was not within single contingency limits from 15:06 to16:06. In addition to day-ahead planning, the system should have been restudied after the forced outage of Eastlake 5.
>
> FirstEnergy did not perform adequate day-ahead operations planning studies to ensure that FirstEnergy had adequate resources to return the system to within contingency limits following the possible loss of their largest unit, Perry 1. After Eastlake 4 was forced out on August 13, the

---

[72] North American Electric Reliability Corporation. 2004. *August 14, 2003 Blackout: NERC Actions to Prevent and Mitigate the Impacts of Future Cascading Blackouts.* February 10. p. 100.

operational plan was not modified for the possible loss of the largest generating unit, Perry 1.

The *NERC Blackout Report* implies that, if FirstEnergy had employed look-ahead studies using tools such as power flow, the cascading condition that caused the blackout of August 14, 2003, might have been avoided.

Summary of Findings

This section of the report examines how survey respondents, involved in operating transmission systems, operate, maintain, and utilize power-flow applications and discusses key issues faced by those who use power flow.

Power-flow applications, which are important for monitoring system reliability, appear to be used widely to simulate system conditions and to troubleshoot EMS problems. Routinely using them to perform look-ahead studies would further enhance operators' situational awareness.

The survey reveals a lack of systematic procedures for analyzing a failed power flow solution that could indicate potential voltage collapse. RTBPTF concludes that tools should be developed to warn operators of a failed solution or potential problems.

Prevalence and Perceived Value of Power Flow

There were 45 unique respondents to this section of the survey, including all 17 of the RCs surveyed. Table 2.8-1 shows that 71 percent of all respondents (32 out of 45) and 94 percent of reliability coordinators (16 out of 17) report having a power flow application. Most respondents (90 percent, or 28 out of 31) consider the application "essential" for situational awareness; a few (10 percent, 3 out of 31) consider it "desirable"; no respondents consider it to be of minimal or no value. Table 2.8-1 summarizes responses to general questions concerning power-flow applications.

NOTE: In the columns of all tables in this section that list percentages of respondents, the percentage value is preceded by the number of respondents out of the total that gave the indicated response. For example, "32/38=84%" means that 32 out of a total of 38 respondents, or 84% out of respondents, gave the indicated response.

Question	All	RCs	Others
Do you have on-line power flow?	32/45=71%	16/17=94%	14/26=54%
If you do not have on-line power flow, do you plan to add it in the future?	7/13=54%	0/1=0%	7/12=58%
Is your on-line power flow operational?	31/32=97%	16/16=100%	13/14=93%
Do you rate your power flow "essential" as a reliability tool for situational awareness?	28/31=90%	13/16=81%	13/13=100%
Do you rate your power flow "desirable" as a reliability tool for situational awareness?	3/31=10%	3/16=19%	0/15=0%
Do you rate your power flow as of "minimal value" as a reliability tool for situational awareness?	0/31=0%	0/16=0%	0/15=0%
Do you rate your power flow as of "no value" as a reliability tool for situational awareness?	0/31=0%	0/16=0%	0/13=0%

Table 2.8-1 — Prevalence and Perceived Value of Power Flow

Application Interfaces and Features

Table 2.8-2 summarizes the characteristics of respondents' power-flow applications, and shows that all respondents report that their power-flow applications are integrated fully with their SCADA and EMS systems. In addition, EMS vendors appear to offer power flow as a standard product.

Power-Flow Application Characteristics	All	RCs	Others
Power flow fully integrated with production SCADA/EMS	30/30=100%	15/15=100%	13/13=100%
Power flow fully integrated with non-production SCADA/EMS	0/30=0%	0/15=0%	0/13=0%
Power flow supplied by SCADA/EMS vendor	30/31=97%	15/16=94%	13/13=100%
Power flow supplied by other vendor	1/31=3%	1/16=6%	0/13=0%
Power flow developed in-house	0/31=0%	0/16=0%	0/13=0%

Table 2.8-2 — Characteristics of Applications

Both operators and operations support staff use power flow applications. Eighty-one percent of all respondents (25 out of 31) report that operators or control room staff are the primary users of the applications; approximately 48 percent (15 out of 31) indicate that operations support staff also use the applications (see Table 2.8-3). These numbers indicate that power-flow applications are used widely as a tool to simulate system conditions and to troubleshoot EMS problems.

Users	All	RCs	Others
System operators and/or other control room staff	25/31=81%	12/16=75%	11/13=85%
Operations support staff	15/31=48%	7/16=44%	7/13=54%
Supervisory and/or management staff	4/31=13%	0/16=0%	4/15=27%

Table 2.8-3 — Primary Users

The survey also asked what applications are interfaced with power flow, and what is the source of the base case provided to initialize the power-flow application.

Table 2.8-4 summarizes the responses.

Application	All	RCs	Others
SCADA	17/31=55%	8/16=50%	9/15=60%
Alarm tools	6/31=19%	2/16=13%	4/15=27%
Monitoring and visualization techniques	18/31=58%	9/16=56%	9/15=60%
Network topology processor	15/31=48%	10/16=63%	5/15=33%
State estimator	28/31=90%	14/16=88%	14/15=93%
Contingency analysis	26/31=84%	14/16=88%	12/15=80%
Critical facility loading assessment	1/31=3%	1/16=6%	0/15=0%
Study real-time maintenance	7/31=23%	3/16=18%	4/15=27%
Study network topology processor	19/31=61%	10/16=63%	9/15=60%
Study contingency analysis	30/31=97%	16/16=100%	14/15=93%
Study critical facility loading assessment	1/31=3%	1/16=6%	0/15=0%

Table 2.8-4 — Applications Interfaced with Power Flow

Table 2.8-4 indicates that power-flow applications are interfaced primarily with the state estimator (90 percent, or 28 out of 31), contingency analysis (84 percent, or 26 out of 31), and study contingency analysis (97 percent, or 30 out of 31). Data from
Table 2.8-4 suggest that power-flow applications also are used frequently to provide a base case that is used in other applications, such as study contingency analysis or visualization techniques.

Table 2.8-5 and Table 2.8-6 summarize other characteristics of power-flow applications. Industry members most commonly use a full AC algorithm. The slack bus chosen varies evenly between single unit/bus or distributed generation slack. Full survey results for power flow are provided in Appendix D, which summarizes results not detailed in this Summary of Findings.

What Algorithm Does Your Power Flow Typically Use?	All	RCs	Others
Full AC	21/31=68%	12/16=75%	9/15=60%
Decoupled	9/31=29%	3/16=19%	6/15=40%
Other	1/31=3%	1/16=6%	0/15=0%

Table 2.8-5 — Power-Flow Algorithms

What Type of Slack Does Your Power Flow Typically Use?	All	RCs	Others
Single unit or load bus	15/31=48%	7/16=44%	8/15=53%
Distributed generation	12/31=39%	7/16=44%	5/15=33%
Distributed load	3/31=10%	1/16=6%	2/15=13%

Table 2.8-6 — Power-Flow Slack Bus

Although most respondents use their power-flow application to monitor the entire internal system for thermal and voltage violations, NERC reliability Principle 7 emphasizes the need for wide-area monitoring. As illustrated in Table 2.8-7, only 42 percent of respondents (13 out of 31) monitor selected external facilities that affect their internal systems, and 29 percent of respondents (9 out of 31) monitor no external facilities at all. Therefore, RTBPTF believes that standards for monitoring external facilities need to be developed. For more details, see Section 4.2, Modeling Practices and Tools.

External System Monitoring	All	RCs	Others
All/most external facilities impacting internal system are monitored	9/31=29%	7/16=44%	2/13=16%
Only select external facilities impacting internal system are monitored	13/31=42%	6/16=37%	6/13=46%
No external facilities are monitored	9/31=29%	3/16=19%	5/13=38%

Table 2.8-7 — External System Monitoring Using Power Flow

Verifying Accuracy

Survey results reveal that respondents use various methods to verify the accuracy of power-flow solutions. As illustrated in Table 2.8-8, for example, 61 percent (19 out of 31) of respondents use real-time applications (i.e., telemetry data system, alarm tools, state estimator, or contingency analysis) or other power-flow applications (i.e., offline power flow) to verify results of online power flow.

If a Power-Flow Solution is Questionable, How Do You Verify the Accuracy of the Solution?	All	RCs	Others
Compare results with distribution factors	4/31=13%	4/16=25%	0/13=0%
Compare results with another power-flow application	19/31=61%	9/16=56%	8/13=62%
Compare results with results from another case	17/31=55%	9/16=56%	6/13=46%
Compare results with another TOP's results	10/31=32%	6/16=38%	4/13=31%
Compare results with another study application's results	11/31=35%	7/16=44%	4/13=31%
Compare results with another real-time application's results	19/31=61%	12/16=75%	6/13=46%

Table 2.8-8 — Methods for Verifying Power-Flow Results

The importance of power-flow applications to reliability and the variety of methods used to verify results indicate a need to develop documented procedures for verifying the accuracy of results. The procedures should reflect the purpose for which the online power flow application is being used. For example, if power flow provides the base case for contingency analysis in a real-time system, results should be verified using real-time applications or SCADA.

A few respondents (20 percent, or 6 out of 30) indicate that they have tools/procedures to evaluate whether a non-converged power-flow solution indicates a possible voltage collapse. RCs (19 percent, or 3 out of 16) report a similar dearth of tools/procedures for identifying a potential voltage collapse indicated by a failed power-flow solution. Additionally, only 29 percent of all respondents (9 out of 31) report having procedures to detect and notify staff members of failed power-flow solutions. RTBPTF believes that tools should be developed to warn operators of a failed solution and indicate potential problems.

Power Flow in Look-Ahead Studies

Most respondents use power-flow applications to perform look-ahead studies. As shown in Table 2.8-9, eighty percent of all respondents report using power flow to perform hour-ahead to day-ahead analyses. Most users perform these studies on an as-needed basis, as shown in Table 2.8-10.

For Which Time Frames Do You Normally Perform Look-Ahead Power-Flow Studies?	All	RCs	Others
Look-ahead studies for less than 1 hour ahead	14/30=47%	7/16=44%	6/12=50%
Look-ahead studies from 1 hour to 1 day ahead	24/30=80%	11/16=69%	11/12=92%
Look-ahead studies for more than 1 day ahead	18/30=60%	7/16=44%	9/12=75%

Table 2.8-9 — Power Flow in Look-Ahead Studies

At What Periodicity Do You Normally Perform Look-Ahead Power-Flow Studies?	All	RCs	Others
Hourly	4/30=13%	4/16=25%	0/14=0%
Several times per day	5/30=17%	3/16=19%	2/14=14%
Daily	13/30=43%	6/16=38%	7/14=50%
As Needed	25/30=83%	11/16=69%	14/14=100%

Table 2.8-10 — Frequency of Look-Ahead Studies

Finally, the survey indicates that most respondents (46 out of 59) have a user interface to monitor power-flow data and results. Seventy percent of respondents (10 out of 13) who do not have an interface consider one "desirable."

Recommendations for New Reliability Standards

Given the need to support NERC reliability principles, and based on the inconsistencies identified in the Summary of Findings, RTBPTF recommends the following modifications to reliability standards.

Look-Ahead Analysis Requirement

Standard TOP-002 (Normal Operations Planning) and Standard IRO-004 (Reliability Coordination — Operations Planning) require reliability entities to perform day-ahead studies. Requirement R11 of TOP-002 states:

> [T]he Transmission Operator shall perform seasonal, next-day, and current-day bulk electric system studies to determine SOLs. Neighboring Transmission Operators shall utilize identical SOLs for common facilities. The Transmission Operator shall update these bulk electric system studies as necessary to reflect current system conditions; and shall make the results of Bulk Electric System studies available to the Transmission Operators, Balancing Authorities (subject to confidentiality requirements), and to its Reliability Coordinator.

The Purpose Statement for Standard IRO-004 says,

> [E]ach Reliability Coordinator must conduct next-day reliability analyses for its Reliability Coordinator Area to ensure the Bulk Electric System can be operated reliably in anticipated normal and Contingency conditions. System studies must be conducted to highlight potential interface and other operating limits, including overloaded transmission lines and transformers, voltage and stability limits, etc. Plans must be developed to alleviate System Operating Limit (SOL) and Interconnection Reliability Operating Limit (IROL) violations.

The requirement listed in IRO-004 and TOP-002 primarily focuses on day-ahead analysis and does not specify any requirements for hour-ahead analysis. To mitigate approaching SOL and IROL violations it is necessary to perform hour-ahead studies along with day-ahead and seasonal studies.

Recommendation – S14

Perform one-hour-ahead power-flow simulations to assess approaching SOL and IROL violations and corresponding measures.

RTBPTF Recommendation

To assess approaching SOL and IROL violations, RTBPTF recommends modifying TOP-002 and IRO-004 to include the following requirement:

> PR1: Each Reliability Coordinator and Transmission Operator shall, at a minimum, perform one-hour-ahead Power-Flow simulations during the following:
> - Occurrence of critical system event
> - Extreme load conditions
> - Large power transactions
> - Major planned outages

Fore the above requirement, RTBPTF recommends the following measure:

> PM1: Documented evidence showing results of hour-ahead studies and mitigation plans if needed must be kept by Reliability Coordinators and Transmission Operators.

Rationale

This recommendation addresses the following deficiency identified in the Blackout Report:

> FE did not perform adequate hour-ahead operations planning studies after Eastlake 5 tripped off-line at 13:31 to ensure that FE could maintain a 30-minute response capability for the next contingency. The FE system was not within single contingency limits from 15:06 to 16:06. In addition to day-ahead planning, the system should have been restudied after the forced outage of Eastlake 5.

The survey reveals that performing look-ahead studies is a prevailing practice. Forty-seven percent of all respondents perform look-ahead studies for less than 1 hour ahead, and 80 percent (24 out of 30 perform studies from 1 hour to 1 day ahead (see Table 2.8-9). An overwhelming 83 percent (25 out of 30) indicate that studies are done as needed (see Table 2.8-10).

The practice/process of performing look-ahead analysis during a major system event or when the power system is a stressed state suggests that reliability entities need to be more prepared. Systems are designed to withstand n-1 contingencies when they occur. However, changing conditions (e.g., scheduled system configuration, generation dispatch, interchange scheduling, and demand pattern changes) over the hour-ahead timeframe may need operator action in anticipation of these changing conditions. Performing look-ahead studies enhances operator situational awareness.

Recommendation – G6

Perform one-hour ahead contingency analysis to identify potential post-contingent problems approaching in next hour.

Recommendations for New Operating Guidelines

RTBPTF has recommended minimum standards for look-ahead analysis by listing events when one-hour-ahead analysis must be done. As an operating guideline and best practice, RTBPTF recommends performing a contingency analysis simulation using the one-hour-ahead power-flow base case every hour, employing an automatic method. This will identify potential post-contingent problems approaching in next hour.

Recommendation – A9

Verify accuracy of one-hour power-flow and contingency analysis results and ability to detect a potential voltage collapse revealed by a failed power-flow solution.

Areas Requiring More Analysis

RTBPTF identified the following two areas that require additional analysis:

Verification of Accuracy

The survey reveals that respondents use various methods to verify the accuracy of power-flow solutions. The methods and tolerances used in verifying results may depend on the purpose of the simulation. For example, an RC running power flow to simulate real-time conditions should verify the accuracy of results by comparing voltages, angles, and flows with those derived from state estimator. Because RTBPTF recognizes the need to further analyze and establish methods for verifying power-flow results, the task force recommends performing a detailed survey to identify current practices, which in turn could lead to developing standards or guidelines related to methods for verifying power-flow results.

Detection of Voltage Collapse

The survey reveals a lack of systematic procedures and tools for analyzing a failed power-flow solution that could indicate potential voltage collapse. RTBPTF suggests additional review and analysis of existing methods, tools, and algorithms for identifying a potential voltage collapse revealed by a failed power-flow solution.

Examples of Excellence

RTBPTF did not identify any Examples of Excellence related to Power Flow.

Section 2.9
Study Real-Time Maintenance

Definition
Study real-time maintenance (SRTM) is a study function that simulates real-time network applications (i.e. NTP, state estimator, contingency analysis etc.) and debugs problems without affecting the operation of the real-time applications. An SRTM tool can be an online application integrated with the production EMS system, an application integrated with a non-production EMS system [i.e. development, test, dispatcher training simulator (DTS) system etc.], or an offline application. (Note: Any reference to DTS is in the context of application maintenance, not training, which is not in RTBPTF's scope.)

Background

Given the complexity of the applications that make up EMS networks as well as their interaction with the telemetry, network model and actual power system, support staff must be able to quickly and easily recreate, debug, and resolve problems without affecting the real-time applications themselves. Without this capability, critical real-time network applications for monitoring and maintaining system reliability might be unavailable for extended periods.

Diminished situational awareness, attributable to the lack of availability of critical real-time network applications, contributed to the blackout of August 14, 2003. The causal analysis described in the *Outage Task Force Final Blackout Report*[73] reveals that the contingency analysis application in FE's control center was unavailable, and the state estimator and contingency analysis applications in the MISO control center were unavailable for some periods. Recommendation 37 in the *Outage Task Force Final Blackout Report* calls on entities to "[i]mprove IT forensic and diagnostic capabilities."[74] The report states that "[control areas] and [reliability coordinators] should seek to improve internal forensic and diagnostic capabilities, ensure that IT support personnel who support EMS automation systems are familiar with the systems' design and implementation, and make certain that IT support personnel who support EMS automation systems are trained in using appropriate tools for diagnostic and forensic analysis and remediation." RTBPTF believes that SRTM qualifies as a tool for performing diagnostic and forensic analysis and remediation of state estimator and contingency analysis applications, and that it is most effectively implemented independently, without hindering the real-time application it is analyzing.

Details in the *Outage Task Force Final Blackout Report* indicate that FE's contingency analysis application did not function properly and was not

[73] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April. pp. 17–22
[74] Ibid. p. 166

maintained adequately. FE operators reported on-going problems with results from their real-time contingency analysis beginning when the application was installed in 1995. In addition, the application was not run in real-time mode. RTBPTF believes that if FE had adequate, trained, and experienced support staff who properly implemented their contingency analysis and routinely used an SRTM application to debug it and resolve problems, many of the causes of the August 14, 2003, blackout could have been avoided.

Based on details in the *Outage Task Force Final Blackout Report*, MISO support staff had a standard procedure for debugging real-time state estimator solutions by disabling the automatic triggers that normally would initiate real-time state estimator and contingency analysis. This practice resulted in periods when the applications were unnecessarily unavailable. Again, RTBPTF believes that if MISO had used an SRTM application to debug state estimator solutions, applications would have remained continuously available.

The SRTM section of the report summarizes reported use of and practices surrounding the SRTM (or equivalent) application.

Summary of Findings

This section of the report summarizes reported use of and practices surrounding the SRTM (or equivalent) application.

Real-Time Tools Survey results show that most RCs have, successfully use, and highly value SRTM. A total of 45 respondents answered the questions in the SRTM section of the survey. For respondents who perform multiple roles, each role is counted in the totals. Sixteen RCs responded, 25 TOPS responded uniquely (i.e., those that do not play any other role); and 2 balancing authorities (BAs) responded uniquely. Because so few BAs responded, the discussion in this section is based on results from RCs and TOPs only.

Prevalence and Perceived Value of SRTM

Table 2.9-1 summarizes responses to general questions about SRTM. Most RCs (88 percent) and 32 percent of those responding uniquely as TOPs indicate that their organizations have an SRTM tool. In addition, 95 percent of respondents with operational SRTMs consider the features “essential” or “desirable” for providing situational awareness.

NOTE: In the columns of all tables in this section that list percentages of respondents, the percentage value is preceded by the number of respondents out of the total that gave the indicated response. For example, “32/38=84%” means that 32 of a total of 38 respondents, or 84% of respondents, gave the indicated response.

General Survey Questions	All	RCs	TOPs
Do you have SRTM?	22/45 = 49%	14/16 = 88%	8/25 = 32%
Is your SRTM operational?	21/22 = 95%	13/14 = 93%	8/8 = 100%
If it is not operational, do you plan to make your SRT) operational?	1/1 = 100%	1/1 = 100%	0/0 = NA
Do you rate your SRTM "essential" as a reliability tool for situational awareness?	11/21 = 52%	8/13 = 62%	3/8= 38%
Do you rate your SRTM "desirable" as a reliability tool for situational awareness?	9/21 = 43%	4/13 = 31%	5/8 = 63%
Do you rate your SRTM to be of "minimal value" as a reliability tool for situational awareness?	1/21 = 5%	1/13 = 8%	0/8 = 0%
Do you rate your SRTM to be of "no value" as a reliability tool for situational awareness?	0/21 = 0%	0/13 = 0%	0/8 = 0%

Table 2.9-1 — General Responses Regarding SRTM

Respondents' high opinion of SRTM is conveyed by comments such as the following:

> "This tool allows [us] to debug cases without affecting the Real Time System."
>
> "Sensational tool to debug real-time problems without affecting real-time applications."
>
> "Excellent feature to find the convergence problem in a network solution."

Characteristics of SRTM Applications

Most (86 percent) of respondents who have operational SRTM tools report that their SRTM is either off-the-shelf or customized somewhat. Most (81 percent) report having acquired their SRTM from their SCADA/EMS vendor. A preponderance (91 percent) report that their SRTM is fully integrated with either their production or non-production SCADA/EMS system (see Table 2.9-2). These results indicate that SRTM is a standard application offered by EMS vendors and is feasible to implement although most users perform some level of customization.

SRTM Characteristics	All	RCs	TOPs
Highly customized	3/21 = 14%	0/13 = 0%	3/8 = 38%
Off-the-shelf with some customization	12/21 = 57%	10/13 = 77%	2/8 = 25 %
Off-the-shelf	6/21 = 29%	3/13 = 23%	3/8 = 38%
Supplied by SCADA/EMS vendor	17/21 = 81%	11/13 = 85%	6/8 = 75%
Supplied by other vendor	2/21 = 10%	2/13 = 15%	0/8 = 0%
Developed in-house	2/21 = 10%	0/13 = 0%	2/8 = 25%
Fully integrated with production SCADA/EMS	18/21 = 86%	10/13 = 77%	8/8 = 100%
Fully integrated with non-production SCADA/EMS	1/21 = 5%	1/13 = 8%	0/8 = 0%
Interfaced to production SCADA/EMS	2/21 = 10%	2/13 = 15%	0/8 = 0%
Stand-alone	0/21 = 0%	0/13 = 0%	0/8 = 0%

Table 2.9.2 — Characteristics of SRTM

Most (62 percent) of RCs who have operational SRTM applications report that EMS/IT support staff are the primary users. TOP responses suggest that system operators and/or other control room staff, operations support staff, or EMS/IT support staff are all equal users (see Table 2.9-3). Note that each respondent could choose multiple primary users. Survey results indicate that it is primarily support staff, not system operators, who use SRTM, but a relatively high percentage of TOPs rely on system operators and/or other control room staff to use SRTM.

Primary SRTM Users	All	RCs	TOPs
System operators	8/21 = 38%	3/13 = 23%	5/8 = 63%
Operations support staff	11/21 = 52%	6/13 = 46%	5/8 = 63%
EMS/IT support staff	13/21 = 62%	8/13 = 62%	5/8 = 63%
Supervisory/Management	3/21 = 14%	0/13 = 0%	3/8 = 38%
Others	1/21 = 5%	0/13 = 0%	1/8 = 13%

Table 2.9-3 — Primary Users of SRTM

Most respondents that have an operational SRTM application report that it can simulate NTP, topology error detection, state estimator, and contingency analysis. Only a few report that they can simulate CFLA or other applications (see Table 2.9-4). Note that each respondent could choose multiple applications.

Applications	All	RCs	TOPs
Network topology processor	20/21 = 95%	12/13 = 92%	8/8 = 100%
Topology error detection	13/21 = 62%	7/13 = 54%	6/8 = 75%
State estimator	19/21 = 90%	12/13 = 92%	7/8 = 88%
Contingency analysis	19/21 = 90%	13/13 = 100%	6/8 = 75%
Critical facility loading assessment	1/21 = 5%	1/13 = 8%	0/8 = 0%
Others	3/21 = 14%	3/13 = 23%	0/8 = 0%

Table 2.9-4 — Real-Time Applications that SRTM Can Simulate

Recommendations for New Reliability Standards

Requirement R9 of NERC Standard IRO-002 mandates that RCs have plans and procedures for minimizing tool outages:

> [E]ach Reliability Coordinator shall control its Reliability Coordinator analysis tools, including approvals for planned maintenance. Each Reliability Coordinator shall have procedures in place to mitigate the effects of analysis tool outages.

RTBPTF focuses on evaluating the capabilities of operators' critical real-time tools, not how those applications are maintained. RTBPTF believes that requirement R9 is sufficient to maintain the viability of analytical tools and does not recommend developing specific SRTM standards at this time.

Although the RTBPTF recommends no specific SRTM standards, SRTM capabilities should be considered when developing standards for maintaining and supporting other (critical) real-time applications that do require standards. Rather than requiring standards for SRTM, RTBPTF recommends establishing operating guidelines.

Recommendation – G7

Use the study real-time maintenance application to reproduce real-time snapshots.

Recommendations for New Operating Guidelines

Because survey results show that most RCs have, successfully use, and highly value SRTM, RTBPTF considers it appropriate to develop operating guidelines for this tool. The operating guidelines should help SRTM support the standards established for the critical real-time applications that do require standards (e.g., NTP, state estimator, and contingency analysis). SRTM supports the notion of "[i]mprove[d] IT forensic and diagnostic capabilities," as described in Recommendation 17 of the *Outage Task Force Final Blackout Report.* Users of real-time network applications may be able to improve their maintenance tools and practices based on achieving the capabilities recommended in the following operating guidelines for SRTM.

1. Whoever performs the RC, BA, or TOP function should be capable of using their SRTM application to simulate, at a minimum, the following real-time network applications:
    - NTP
    - state estimator
    - contingency analysis

2. If an entity implements its SRTM capability in a non-production environment, whoever performs the RC, BA, or TOP function should be capable of quickly and easily synchronizing that environment to the production environment (via network model, software, or user interface) so that real-time problems or snapshots can be reproduced.

3. Whoever performs the RC, BA, or TOP function should have the following SRTM capabilities:

- Ability to initiate the SRTM application from each of the critical real-time applications
- Ability to automatically save and archive real-time cases from various time periods
- Ability to automatically save and archive real-time aborted and non-converged cases
- Ability to initiate the SRTM application from an archive of historical real-time cases
- Ability, if requested, to save an SRTM case for future use
- Ability of SRTM to precisely duplicate real-time applications
- Ability to initiate study power flow and other study applications from a saved SRTM-analyzed case
- Possession of a distinct SRTM user interface

Recommendation – A10

Obtain additional information on how the study real-time maintenance application is utilized to enhance debugging capability.

Areas Requiring More Analysis

Before NERC establishes operating guidelines for SRTM and standards for maintaining and supporting critical real-time network applications, RTBPTF recommends obtaining additional details about how most industry members utilize SRTM capabilities. Based on a few survey comments, some respondents may believe that some of the capabilities of their study network application and DTS represent full SRTM capabilities. Although this idea is not necessarily incorrect, there are some subtle differences among these capabilities.

It may be impossible, for example, to recreate all real-time contingency analysis problems using study contingency analysis, because the base case for real-time contingency analysis may be the real-time state estimator solution whereas the base case for study contingency analysis may be a power-flow solution derived from the real-time state estimator solution.

It may be impossible to use DTS to recreate all problems in state estimator solutions because the state estimator in DTS may use measurements from the simulation rather than from real-time SCADA data.

If the full range of SRTM capabilities is accessible, network applications can be run and debugged exactly as they are, so that problems can be reproduced. If SRTM capabilities are implemented on a non-production, rather than production, EMS that system must be synchronized (regarding network model, software, and user interface) with the production EMS system to enable problems to be reproduced.

Examples of Excellence

RTBPTF cites as an example of excellence the use of an SRTM by PJM that includes a user interface that looks and feels exactly like the production network applications (See EOE-11 in Appendix E). SRTM allows PJM to quickly and easily recreate, debug, and resolve network applications problems without impacting the real-time network applications and use of this application has increased the overall availability of the real-time network applications.

Section 2.10
Voltage Stability Assessment

Definition

Voltage stability is defined as how much more load or transfer the system can sustain in a given direction before it encounters voltage instability. Voltage stability analysis (VSA) is an application that executes in near real-time and aids in the determination of system operating limits based on the voltage stability assessment using a recent snapshot of the real-time system. VSA may derive minimum voltages at key buses below which voltage collapse might occur if the system experiences additional stresses. It may also provide information on minimum dynamic reactive reserves required in local areas.

Note that this definition is not referring to offline voltage stability analysis tools that are usually used by engineering staff for medium-term or long-term studies. However, if such tools are used for studying near-real-time snapshots in answer to voltage stability questions by operators, they would be included in the VSA section of the Real-Time Tools Survey.

Summary of Findings

The VSA section of the Real-Time Tools Survey evaluates use of documented practices for monitoring voltage conditions. Survey responses indicate that although VSA applications are clearly useful, they apparently have not yet reached a stage of maturity that would render them a critical tool for reliable system operation.

VSA tools are used by a limited group of respondents. Only 6 out of the 14 reliability coordinators (RCs) (43 percent) and 6 out of the 24 transmission operators (TOPs) (25 percent) who responded to this section of the survey report having VSA capability. Just 5 RCs (36 percent) and 3 TOPs (13 percent) report having an operational VSA application. Interest in VSA may be growing, however, because 2 RCs and 5 TOPs plan to add a VSA package. In addition, 3 RCs and 6 TOPs plan to make their current application operational. The 5 RCs who have operational VSA applications deem the application ”essential” or “desirable” for monitoring system reliability. In addition, 2 out of 3 TOPs consider the application “desirable,” although one TOP considers it of “minimal” value.

Three RCs (of 5 responding) and 2 TOPs (of 3 responding) reported that their VSA applications can assess voltage stability (i.e., indicate pass/fail) for a set of contingency conditions. Some respondents indicated even though VSA is not widely used today, it could be of greater benefit if it was able to identify voltage stability margins and optimize the margin of voltage stability. The applications should be designed to display both the enhanced stability margin and a range of corrective actions. With further development, VSA applications have the potential to become another critical tool for monitoring system reliability in real time.

Users

Survey respondents identify operations planning staff, RCs, system operators, and control room staff as the primary users of VSA. Respondents who have operational VSA applications report that operations planning staff are the users (all 5 RCs and all 3 TOPs). Three RCs include control room operators as VSA users, while a few respondents identify EMS support staff, system planners, and “others” as users.

Functionality and Analytical Methods

Most VSA applications were developed in-house or by a third-party vendor other than the EMS vendor (reported by 4 out of 5 RCs and 2 out of 3 TOPs). Two out of 5 RCs (40 percent) and one out of 3 TOPs (33 percent) report that their application is highly customized. No RCs and only one TOP report using an off-the-shelf VSA product.

Four out of 5 RCs and both TOPs who responded report that their VSA applications are interfaced with state estimator solutions. VSA is most frequently interfaced with the real-time state estimator and contingency analysis applications although it was reported to be integrated with other applications such as unit commitment.

Three out of 5 RCs and 2 out of 3 TOPs report that they can assess voltage stability (i.e., determine pass/fail) for a set of contingency conditions derived from current system conditions. Three RCs and 2 TOPs consider this feature to be desirable or essential. Four out of 5 RCs report that their VSA application is used to evaluate fewer than 100 contingencies. While 1 respondent noted that it maintains a separate contingency list, 3 out of 5 RCs reporting indicated that the contingency list analyzed is derived from the EMS. Two of the 3 TOPs reporting also indicated the contingency list used is derived from the EMS.

The VSA application typically executes as a real-time tool. Three out of 5 RCs and all 3 TOPs who use the application report relying on a periodic trigger to execute VSA. Similar percentages use manual triggers. Respondents do not report using event or disturbance triggers. Frequency of execution ranges from once every minute to once every 60 minutes. The few RCs who responded to this section of the survey report that the application takes from 2 to 10 minutes (as measured by the wall clock) to execute.

Only 3 RCs and 2 TOPs responded to questions about the analytical methods that their VSA program employs to assess voltage stability. The applications of 3 RCs and both TOPs utilize Power/Voltage (PV) analysis. Other analytical methods include Reactive/Voltage (QV) analysis (0 RCs but both TOPs reporting they have the application); singularities in the Jacobian matrix (1 RC); power flow non-convergence (1 RC); and detailed time simulation (1 RC). Two respondents comment that they use other methods such as a ”continuation power flow” or ”model analysis” to assess the network’s voltage stability.

Two out of 5 RCs and 3 out of 4 TOPs state that their VSA applications calculate margins of voltage stability (see definition above). TOPs and RCs responded somewhat differently to the question of perceived value of this function as all 3 TOPs who have this feature say they use the ability to calculate voltage stability margins and consider it desirable. In contrast, although just 2 RCs report using a voltage stability margin application, both consider it essential. Three RCs and 1 TOP also indicated that they would consider the feature desirable if they had the ability to calculate voltage stability margins.

One out of 2 RCs reports that the application automatically assesses stability for increasing levels of load, and both RCs responding to the question indicate that their program automatically assesses stability for increasing levels of power transfer from an area (or set of areas) to another area. One of 3 TOPs responded that they use a load-increase-based method, and 1 of 3 TOPs responded that they use the increasing power transfer technique to assess voltage stability margins. Another TOP notes that they use a “direct analytical method” but does not describe the feature further.

The survey also asked whether respondents were incorporating advanced VSA tools to develop optimized margins of voltage stability. No RCs and only 1 out of 4 TOPs report having the capability to optimize or develop combinations of mitigation options to increase the system’s margin of voltage stability in near-real time for a set of contingency conditions with the ability to display both the enhanced stability margin and a set of corrective actions. Although only one entity reports using this feature, of respondents who lack the feature, all RCs (5) and TOPs (3) deem it desirable.

Three out of 5 RCs and 2 out of 4 TOPs report that their VSA applications have tools that display/visualize the level of voltage stability as an index of PV or QV curves or via tabular displays. Just 2 RCs and 2 TOPs report using the features although those same 4 respondents rate the feature “desirable” or “essential” (see Table 2.10-1).

NOTE: In the columns of all tables in this section that list percentages of respondents, the percentage value is preceded by the number of respondents out of the total that gave the indicated response. For example, “32/38=84%” means that 32 out of a total of 38 respondents, or 84% of respondents, gave the indicated response.

What Techniques Does the Program Use to Visualize the Voltage Stability of Your Power System Network?	All Respondents	RCs
Color-coded meters	1/4 = 25%	1/2 = 50%
Graphs of PV or QV curves	0/ 4 = 0%	0/2 = 0%
Other(s)	4/4 = 100%	2/2 = 100%
Spatial visualization of voltage stability margins by the boundaries	3/4 = 75%	2/2 = 100%
Tabular displays	0/4 -= 0%	0/2 = 0%
Voltage stability index	1/4 = 25%	1/2 = 50%

Table 2.10-1 — Techniques Used to Display Voltage Stability

One respondent comments that their application can generate SCADA alarms. Four RCs continuously monitor the availability of their VSA application, and 3 notify on-call or on-site support staff of application failures.

Recommendations for New Reliability Standards

RTBPTF is not recommending the development of new reliability standards related to VSA. Given the limited application of VSA within the industry, as indicated by the survey results summarized above, RTBPTF does not recommend developing new reliability standards for VSA applications.

Recommendations for New Operating Guidelines

RTBPTF is not recommending Operating Guidelines related to VSA. Given the limited application of VSA within the industry, as indicated by the survey results summarized above, RTBPTF does not recommend developing new operating guidelines for VSA applications.

Recommendation – A11

Assess the voltage stability assessment (VSA) application to learn how the VSA can be enhanced to become more widely used.

Areas Requiring More Analysis

RTBPTF believes that the industry would benefit from having NERC standards that support wide-area security of the bulk electric transmission system through real-time tools that assess voltage stability boundaries. A VSA tool could be used to generate the data required to determine this secure boundary and to identify appropriate corrective actions if needed. At present, VSA tools are used only by operations planners and by very few organizations. The survey did not determine whether the lack of wide use of this tool is attributable to the application being problematic, the results being unreliable, or the results failing to provide clear and actionable information. RTBPTF recommends that VSA capabilities be assessed further to learn why VSA tools are not used more widely, and how they could be enhanced to become more useful and more broadly used.

Examples of Excellence

RTBPTF cites the work of PJM to enhance its real-time VSA to provide control actions to avoid collapse and increase stability margins as an example of excellence (See EOE-12 in Appendix E).

Section 2.11
Dynamic Stability Assessment

Definition

Dynamic Stability Assessment (DSA) is an application (or a suite of applications) executing in near-real time that aids in the determination of stability-related system operating limits using a snapshot of the real-time system (i.e., current state estimator output). It may also provide an indication of dynamic stability margin for the most critical fault/contingency condition.

Note that this definition is not referring to offline stability analysis tools that are usually used by engineering staff for medium-term or long-term studies. However, if such tools are used for studying near-real-time snapshots to answer operators' voltage stability questions, these tools should be included in the DSA section of the Real-Time Tools Survey.

Summary of Findings

The DSA section of the Real-Time Tools Survey evaluates use of DSA applications for monitoring system conditions. Although DSA applications are useful, the responses to the DSA section of the Real-Time Tools Survey indicate that DSA applications are used very little; they apparently have not yet reached a stage of maturity that would render them a critical tool for reliable system operation.

Industry members appear interested in expanding the use of DSA, however. When the applications are further developed, they may have the potential to become another critical tool for monitoring system reliability in real time. As suggested by some of the survey responses, DSA applications would be enhanced if they were able to identify margins of dynamic stability and to optimize or search for combinations of mitigation options to increase the system's margin of stability.

As noted above, the applications apparently have not fully matured, but survey comments such as the following suggest that there is interest in developing DSA applications:

> Our Voltage/Transient Stability tools are not in production yet. We are in the early stages of implementing this tool as a real-time application for our reliability group. We feel that this is a desirable tool that will give the reliability folks another resource to maintain a safe and secure operational network.

It also appears that new installations and application enhancements are either in progress or planned for future implementation that could increase the value of this tool to that of an essential application. In the survey responses, 5 RCs and 5 TOPs state that they plan to add DSA to their suite of applications. This evidence suggests that industry members are interested in using DSA even though only 3 out of 16 RCs (19 percent) and 2 out of 23 TOPs (9 percent) report having a DSA application at this time, and just one RC (and no TOPs) state that their DSA application is operational. Respondents report that the primary users of DSA are operations planning staff and RCs. Results are displayed in various formats, such as a dynamic stability index or a tabular display, color-coded meters, color-coded bar graphs, and spatial visualization.

Based on survey results, DSA software packages are available from SCADA and/or EMS or other vendors. The applications can be applied off-the-shelf or with some customization. Just one TOP indicates that their application was developed in-house.

Functionality and Analytical Methods

Another indication that the application may not yet be mature is that respondents identified a variety of analytical methods for DSA applications, with no single method (or even two methods) emerging as dominant. The applications utilize various approaches, including time-domain simulation, energy function, equal-area criterion, and modal analysis. One RC states that its application utilizes “other direct analytical methods.”

Survey respondents report that a variety of periodic, manual, event or disturbance triggers are employed to start the DSA application.

Online DSA applications are being designed to evaluate dynamic stability not only for the given base conditions but also under various contingency conditions. The contingencies to be studied can be defined from the EMS or via a separate list. Survey results suggest that the applications can, and should, be designed to calculate dynamic stability margins when examining cases with increased loading or power-transfer levels. However, other evidence that the approach to this type of problem is not well established is that some systems estimate critical clearing times and others use energy function values to determine the instability point. Of interest was that 2 respondents report that their software is designed to optimize or search mitigation options to increase the system’s margin of stability in near-real time given a set of contingency conditions. This suggests that the results of DSA can serve an important role.

Recommendations for New Reliability Standards

Given the minimal use of DSA within the industry, as indicated in the survey results summarized above, RTBPTF is not recommending the development of new reliability standards related to DSA.

Recommendations for New Operating Guidelines
Given the minimal use of DSA within the industry, as indicated in the survey results summarized above, RTBPTF is not recommending Operating Guidelines related to Dynamic Stability Assessment.

Recommendation – A12

Assess the dynamic stability assessment (DSA) application to learn how the DSA can be enhanced to become more widely used.

Areas Requiring More Analysis

RTBPTF believes that the industry would benefit from having NERC standards that support wide-area security of the bulk electric system through real-time tools that could identify stability limits or boundaries which define areas of secure operation. Even though current DSA tools may not yet be mature, it appears that many in the industry believe that a DSA tool could be used to generate the data required to identify secure operating boundaries. Consequently, RTBPTF recommends that DSA be assessed further to learn how it currently operates and how it could be enhanced to become more useful, more valuable and more widely used.

Examples of Excellence

RTBPTF did not identify any Examples of Excellence related to DSA.

Section 2.12
Capacity Assessment

Definition

A capacity assessment is an evaluation of the planned and actual amount of power a system can generate. A capacity assessment gives system operators information about the location and availability of critical generating sources and identifies deficiencies in operating reserves. A capacity assessment always considers the real power (MW) that can be generated. When it also includes reactive power capacity (Mvar), it may also consider static devices, such as capacitor banks and reactors.

Background

Power system operators use various methods to monitor the generation resources available to meet power system demands that are changing throughout the day. Unit commitment plans and generation schedules usually are established in advance using one or more applications that prescribe ways to supply predicted system loads. Operators use processes and/or applications that monitor generating reserves on all or parts of the system to make sure capacity is adequate to meet credible generation contingencies and other deviations from the plan. These processes are discussed further in Section 3.1, Reserve Monitoring, of this report.

The applications that assess capacity in real time track both planned and actual generating schedules. These applications are designed to give operators a real-time view of all resources that could be called on if an unplanned event were to result in insufficient capacity in real time.

Tools for assessing capacity complement other wide-area tools and enhance situational awareness. Operators in areas subject to voltage difficulties benefit from increased situational awareness that includes a trustworthy assessment of available, unused real and reactive power capacities. As noted in Section 3.1, Reserve Monitoring, the balance resource and demand standards appear to clearly define real power (MW) operating reserves but not reactive power (Mvar) reserve requirements. Likewise, the calculation of reactive reserves is not well defined in that or any other NERC standard.

Summary of Findings

The capacity assessment section of the Real-Time Tools Survey examines operation, maintenance, and practices related to capacity assessment applications, as reported by those involved in operating transmission systems. This section also addresses the key issues faced by those who use capacity assessment applications.

Survey results reveal that applications for assessing capacity are widely used and generally regarded as important for maintaining awareness of system reliability. Capacity assessment applications, used primarily by control room staff, may incorporate various types of data but always utilize SCADA data. The applications typically receive no scheduled maintenance but are maintained when an alarm indicates the need.

Prevalence and Perceived Value of Applications

As illustrated in Table 2.8-1, 53 percent of all respondents and 69 percent of RCs state that they have a capacity assessment application. Most respondents who have such an application (64 percent) consider it “essential” for situational awareness. Another 28 percent find it “desirable” for situational awareness. Table 2.12-1 summarizes responses to general questions about capacity assessment applications.

NOTE: In the columns of all tables in this section that list percentages of respondents, the percentage value is preceded by the number of respondents out of the total that gave the indicated response. For example, “23/43=53%” means that 23 out of a total of 43 respondents, or 53% of respondents, gave the indicated response.

Survey Question	All Respondents	RCs	Others
Do you have a capacity assessment (or equivalent) application?	23/43 = 53%	11/16 = 69%	12/27 = 44%
Is this application operational?	23/23 = 100%	11/11 = 100%	12/12 = 100%
If you do not have this application, do you plan to add it in the future?	2/19 = 11%	2/5 = 40%	4/24 = 17%
If planned or operational, do you consider it essential?	16/25 = 64%	10/13 = 77%	6/12 = 50%
If planned or operational, do you consider it desirable?	7/25 = 28%	3/13 = 23%	4/12 = 33%
Do you consider the application of minimal or no value?	2/25 = 8%	0/13 = 0%	2/12 = 17%

Table 2.12-1 — Prevalence and Perceived Value of Capacity Assessment Applications

Users of Applications

Capacity assessment applications are used or intended for use by operators and other support personnel (see Table 2.12-2). All respondents that have capacity assessment applications report that these applications are used primarily by operators or control room staff. Approximately 40 percent of all respondents indicate that their capacity assessment applications are also used by operations support staff. These survey results indicate that capacity assessment applications are used widely for monitoring system conditions and energy management issues.

Users	All Respondents	RCs	Others
System operators and/or other control room staff	25/25 = 100%	13/13 = 100%	12/12 = 100%
Management staff	8/25 = 32%	4/13 = 31%	4/12 = 33%
Support staff and others	10/25 = 40%	3/13 = 23%	7/12 = 58%

Table 2.12-2 — Users of Capacity Assessment Applications

Sources of Data for Applications

The survey asked respondents who report using capacity assessment applications what sources of data the application utilizes. All respondents report using SCADA data, but many also rely on manual entries and other sources that do not necessarily provide real-time data. Table 2.12-3 summarizes the responses.

Sources of Data	All Respondents	RCs	Others
SCADA	23/25 = 92%	12/13 = 93%	11/12 = 92%
Manual data	15/25 = 60%	8/13 = 63%	7/12 = 58%
IDC	0/25 = 0%	0/13 = 0%	0/12 = 0%
External applications	7/25 = 28%	6/13 = 46%	1/12 = 8%
Other	3/25 = 12%	3/13 = 23%	0/12 = 0%

Table 2.12-3 — Sources of Data for Capacity Assessment Applications

Three respondents note that “resource plans, load forecast,” and “other data” (typically derived from market data) provide input to capacity assessments.

Approximately 59 percent of all respondents and all RC respondents report they can monitor reactive power capacity (Mvar) as well as real power capacity (MW). Only 12 percent of all respondents indicate that they monitor other types of capacity. Two users note that they monitor the effects of reserves on the ability of critical interfaces to withstand select double-contingencies. These latter responses indicate that some respondents confuse the notion of the various types of capacity (MW, Mvar, other) with how capacity is evaluated (base case, contingency, etc.). The survey questions may not have highlighted this distinction adequately.

Support for Applications

Capacity assessment applications generally do not receive routine attention from support personnel. About 62 percent of all users (57 percent of RCs and 64 percent of TOPs) note that they report any application failures to support personnel. A majority (63 percent) report that support is not automatic or scheduled. Instead, operators call support if an alarm indicates that the application is not functioning. Few (21 percent overall and only 13 percent of RCs) maintain the applications on a regular (weekly) basis rather than an as-needed basis.

Recommendations for New Reliability Standards

Section 3.1, Reserve Monitoring, presents RTBPTF's recommendations for new standards related to operating reserves referenced in this section. Specifically, RTBPTF recommends that requirements be added to existing standards so that operators will monitor critical components of real power operating capacities that affect these reserve quantities.

Recommendations for New Operating Guidelines

RTBPTF is not recommending operating guidelines related to capacity assessment.

Recommendation – A13

Analyze the need to define reactive power (Mvar) capacity requirement and use a Mvar assessment application.

Areas Requiring More Analysis

RTBPTF recommends further analysis of applications that provide comprehensive capacity assessments. This analysis should be coordinated with analysis of tools used to evaluate operating and capacity reserves in Section 3.1, Reserve Monitoring.

Because of the shortcoming noted above, that the current BAL standards do not define reactive power requirements, RTBPTF identified reactive reserve requirements as a major issue; this is discussed in detail in the Introduction to this report. Specifically, RTBPTF believes that mandatory requirements for real-time tools for reactive reserve monitoring would be highly desirable; however, before such recommendations can be formulated, NERC must define technically justified and feasible-to-implement requirements for determining the appropriate amount and location of acceptable reactive reserves and clarifying how reliability coordinators should monitor these reserves.

Examples of Excellence

RTBPTF did not identify any Examples of Excellence related to capacity assessment.

Section 2.13
Emergency Tools

Definition

Emergency tools are applications or procedures that operators use when the power system enters or is about to enter an emergency.[75]

Background

Maintaining the reliability of a power-generating or transmitting facility is a complex enterprise that requires trained and skilled operators, sophisticated computers and communications, and careful planning and design. NERC has developed standards for operating and planning electric systems to safeguard the reliability of transmission grids. The standards are based on seven key concepts that are identified in the *Outage Task Force Final Blackout Report*.[76]

1. Continuously balance power generation and demand.
2. Balance reactive power supply and demand to maintain scheduled voltages.
3. Monitor flows over transmission lines and related facilities so as to stay within thermal (heating) limits.
4. Keep the system in a stable condition.
5. Operate the system so that it remains reliable even if a contingency occurs, such as the loss of a key generator or transmission facility (the "n-1 criterion").
6. Plan, design, and maintain the system to operate reliably.
7. Prepare for emergencies.

The *Outage Task Force Final Blackout Report* further states:

> System operators are required to take the steps to plan and operate a reliable power system, but emergencies can still occur because of external factors such as severe weather, operator error, or equipment failures that exceed planning, design, or operating criteria. For these rare events, the operating entity is required to have emergency procedures covering a credible range of emergency scenarios.[77]

Current NERC standards assign RCs the authority to direct TOPs and BAs to shed load, and TOPs and BAs are required to comply with those directives. No

---

[75] The NERC Glossary defines "emergency" as "[a]ny abnormal system condition that requires automatic or immediate manual action to prevent or limit the failure of transmission facilities or generation supply that could adversely affect the reliability of the Bulk Electric System."
[76] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April. pp. 6–7.
[77] Ibid. p. 10.

standards, however, mandate RCs to maintain situational awareness of their own capability to shed load under real-time operating situations.

Tools/applications for use during a range of credible emergency conditions or scenarios are essential to maintain reliability of the bulk electric system. The Real-Time Tools Survey examined the following types of emergency tools:

- Residential Load or Demand-Side Management – This type of tool enables operators to curtail residential electricity demand[78] for specific appliances. Residential load or demand-side management (DSM) tools consist of the planning, implementing, and monitoring activities that are designed to encourage residential consumers to modify their level and pattern of electricity usage. These activities are also designed to allow shaping of electricity demand through direct computer control of specific appliances. For example, when necessary, operators could turn off air-conditioners of residential customers that sign up for a residential DSM program to reduce electricity demand.

- Commercial/Industrial Load or Demand-Side Management – This type of tool enables operators to curtail commercial/industrial electricity demand. This type of tool is similar to residential Load or DSM but is applied to commercial/industrial customers. A typical application of this type of tool is demand reduction in which operators use direct computer control to disconnect the electric supply feed from the supplying entity.

- Load Reduction by Voltage Reduction – This type of tool enables operators to curtail electricity demand by reducing distribution-level voltages. This scheme usually involves direct computer control (via SCADA systems) to automatic voltage regulating relays on LTC power transformers and step voltage regulators. Controlling the dry contact closure to the regulating relay boosts the sensed voltage of the voltage regulating relay and thus reduces its center band voltage to a lower level.[79] This causes a reduction of the distribution voltage schedule, which reduces electricity demand for a short period.

- Rotating Load Shed – This type of tool enables operators to curtail load by initiating or scheduling load shedding. The *Outage Task Force Final Blackout Report* defines “load shedding” as “… the process of deliberately removing (either manually or automatically) pre-selected customer demand from a power system in response to an abnormal condition, to maintain the integrity of the system and minimize overall customer

[78] The NERC Glossary defines “demand” as “[t]he rate at which electric energy is delivered to or by a system or part of a system, generally expressed in kilowatts or megawatts, at a given instant or averaged over any designated interval of time” or “[t]he rate at which energy is being used by the customer.”
[79] http://www.beckwithelectric.com/infoctr/appnotes/App16.pdf

outages."[80] For this type of tool, rotating load shed refers only to manual load shedding scheduled or initiated by operators via computer control.

Although not all personnel have direct control over all of the emergency tools discussed in the Real-Time Tools Survey (i.e., most RCs do not have direct control over load-shedding applications), if RCs has the tools to monitor the status of emergency tools under their purview, this would enhance situational awareness for both TOPs and RCs. Results form the Emergency Tools section of this report go hand-in-hand with the findings reported in Section 3.5, Load Shed Capability, of this report.

Summary of Findings

The primary finding of the emergency tools section of the Real-Time Tools Survey is that certain types of emergency tools are not widely available, nor are they widely used throughout the industry. The most commonly used emergency tool is rotating load shed, as reported by a small number of respondents. Although few respondents have the emergency tools described in this section, they are nonetheless required to be aware of the situations monitored or controlled by the tools.

Prevalence of Emergency Tools

Table 2.13-1 summarizes the responses to the survey section regarding access to emergency tools. Only 46 percent of respondents to this section of the survey (19 out of 41) indicate that they have emergency tools. This result is surprising given that current NERC reliability standards implicitly require an accessible and functional operator-controlled load-shedding capability (through a tool/application such as rotating load shed). Requirement R2 of Standard EOP-001, for example, states that:

> [T]he Transmission Operator shall have an emergency load reduction plan for all identified IROLs. The plan shall include the details on how the Transmission Operator will implement load reduction in sufficient amount and time to mitigate the IROL violation before system separation or collapse would occur. The load reduction plan must be capable of being implemented within 30 minutes.

In addition, the purpose of Standard EOP-003 is described as: "[a] Balancing Authority and Transmission Operator operating with insufficient generation or transmission capacity must have the capability and authority to shed load rather than risk an uncontrolled failure of the Interconnection." Requirement R8 of EOP-003 states, "[E]ach Transmission Operator or Balancing Authority shall

---

[80] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April. p. 216.

have plans for Operator-controlled manual load shedding to respond to real-time emergencies. The Transmission Operator or Balancing Authority shall be capable of implementing the load shedding in a timeframe adequate for responding to the emergency." All of these requirements imply the necessity for operator-controllable, emergency tools for shedding load.

The low percentage of respondents who report having emergency tools is inconsistent with the findings described in Section 3.5, Load-Shed Capability. In that section of the survey, 74 percent (34 out of 46) of respondents report having some sort of documented practices for maintaining situational awareness of load-shed capability. In short, in the emergency tools section of the survey, 46 percent of respondents indicate they have emergency tools, but in the load-shed section of the survey, 74 percent indicate they have documented practices for maintaining awareness of load-shed capability. This inconsistency may mean that some respondents who report having documented practices for load-shed capability do not use an operator-controlled emergency tool. Instead, these entities may depend entirely on automatic field equipment [i.e., under-frequency load shed (UFLS) or under-voltage load shed (UVLS) relays] to provide load-shed capability.

NOTE: In the columns of all tables in this section that list percentages of respondents, the percentage value is preceded by the number of respondents out of the total that gave the indicated response. For example, "32/38=84%" means that 32 out of a total of 38 respondents, or 84% of respondents, gave the indicated response.

Respondents	Do You Have Emergency Tools, such as Residential Demand-Side Management or Rotating Load Shed?
All	19/41 = 46%
RCs	5/14 = 36%
Others	14/27 = 52%

Table 2.13-1 — Prevalence of Emergency Tools

Perceived Value of Emergency Tools

The survey asked respondents to rate any operational emergency tools that they have available in terms of their situational awareness value. Table 2.13-2 summarizes the responses.

Respondents	How do You Rate Your Emergency Tools as a Reliability Tool for Situational Awareness?	
	Application is “essential”	Application is “desirable”
All	11/18 = 61%	7/18 = 39%
RCs	4/6 = 67%	2/6 = 33%
Others	7/12 = 58%	5/14 = 36%

Table 2.13-2 — Perceived Value of Emergency Tools

Use of Emergency Tools

The data indicate that most respondents who have emergency tools consider them “essential” reliability tools for situational awareness. The survey data also reveal that emergency tools are not used as widely as more common, readily available tools/applications such as the state estimator or contingency analysis. Fewer respondents answered the emergency tools part of the survey than responded to sections concerning other tools/applications. Table 2.13-3 summarizes respondents’ use of the emergency tools. RCs are listed separately.

Application	Do You Have this Emergency Tool?			Do You Use this Emergency Tool?		
	All	RCs	Others	All	RCs	Others
Residential load or DSM	6/20 = 30%	2/6 = 33%	4/14 = 29%	6/6 = 100%	2/2 = 100%	4/4 = 100%
Commercial/industrial load or DSM	12/20 = 60%	3/6 = 50%	9/14 = 64%	12/12 = 100%	7/7 = 100%	5/5 = 100%
Load reduction by voltage reduction	6/20 = 30%	2/6 = 33%	4/14 = 29%	6/6 = 100%	2/2 =1 00%	4/4 = 100%
Rotating load shed	17/20 = 85%	4/6 = 67%	13/14 = 93%	12/17 = 71%	4/4 = 100%	8/13 = 62%

Table 2.13-3 — Use of Emergency Tools/Applications

The primary finding of this survey section is that certain types of emergency tools are not widely available or used within the industry. Table 2.13-3 shows that rotating load shed is the most commonly used operational emergency tool, as reported by a relatively small number of respondents. The recommendations made in Section 3.5, Load-Shed Capability, regarding documented practices for keeping operators aware of the status, availability, magnitude, and time-to-deploy of all load that can be shed on an emergency basis, should be considered in the context of the recommendations made below.

Recommendations for New Reliability Standards

RCs prepare reliability assessments, provide a wide-area view of reliability, and coordinate emergency operations in real time for one or more balancing authorities. As specified in requirement R4 of Standard IRO-005, one of their responsibilities is:

> [A]s portions of the transmission system approach or exceed SOLs or IROLs, the Reliability Coordinator shall work with its Transmission Operators and Balancing Authorities to evaluate and assess any additional Interchange Schedules that would violate those limits. If a potential or actual IROL violation cannot be avoided through proactive intervention, the Reliability Coordinator shall initiate control actions or emergency procedures to relieve the violation without delay, and no longer than 30 minutes. The Reliability Coordinator shall ensure all resources, including load shedding, are available to address a potential or actual IROL violation.

Standard IRO-005 (requirement R3) does not stipulate that the RC must have direct control over load shedding. The standard does specify, however, that RCs have the authority to direct load shedding when necessary. Reliability coordinators are not currently required to be aware of the system load-shed capability required to address a potential or actual IROL violation

Recommendation – S15

Provide real-time awareness of load-shed capability to address potential or actual IROL violations.

RTBPTF Recommendation

Based on survey results, RTBPTF developed a proposed requirement and performance measure to clarify that RCs must be kept aware of load-shed capability in particular because that factor is critical to the ability to address a potential or actual IROL violation.

RTBPTF recommends that Standard IRO-005 be enhanced to require the RC to be aware of the load-shed capability needed to address a potential or actual IROL violation within its area of responsibility. RTBPTF developed the following proposed requirement (PR):

PR1. Each Reliability Coordinator shall have real-time awareness of load-shed capability needed to address a potential or actual IROL violation within its area of responsibility.

RTBPTF developed the following proposed measure (PM) for the above requirement.

PM1 Each Reliability Coordinator shall be required to demonstrate system load-shed capability by having a display (or visualization technique) that shows the real-time status and amount of MW available for shedding load within its area of responsibility.

Rationale

The rationale for this recommendation is discussed extensively in Section 3.5, Load-Shed Capability. Current NERC standards assign RCs the authority to direct their TOPs and BAs to shed load, and TOPs and BAs are required to comply with those directives. No standards, however, specifically mandate that RCs maintain situational awareness of the capability to shed load under real-time operating situations. But the RC must know what can be achieved in response to a directive to shed load.

Recommendations for New Operating Guidelines

RTBPTF is not recommending operating guidelines related to emergency tools.

Recommendation – A14

Research how emergency tools and visualization techniques are used in load shedding plans.

Areas Requiring More Analysis

The survey results are insufficient to establish how personnel use emergency tools, including whether any documented procedures are associated with the tools. RTBPTF recommends further analysis in the following two areas related to emergency tools:

- Research the ways load-shedding plans are established in relation to the various emergency tools. In particular, how does the industry coordinate and prioritize the use of emergency tools (i.e., rotating load shed) with automatic load-shedding schemes? Is there variation in practices and implementation?
- Research current techniques and devices for showing operators the status of load-shed capability. How does the operator know how much load the

emergency tool can shed? How is load-shed capability calculated? What visualization techniques are used to display this information?

Examples of Excellence

RTBPTF did not identify any Examples of Excellence related to emergency tools.

Section 2.14
Other Tools (Current and Operational)

Definition

This section of the report reviews reliability tools for situational awareness that are currently available and operational and that are not specifically addressed in other sections. The tools/applications that are discussed are listed below with their respective definitions:

- Congestion Management Application — This tool relieves network congestion within an entity's service territory using operational means that lie within the entity's control authority, i.e., generation redispatch, curtailment of economic transactions within the entity's service area, switching in capacitor banks, opening low-voltage lines, etc. Typically, this tool would be a security-constrained economic dispatch program, an optimal power-flow program, or an heuristic program that searches for the best solution from a set of options. For an ISO or an RTO, this may be part of the LMP application.

- Inter-Regional Real-Time Coordination for Congestion Management Application — This tool may be different from the congestion management application listed above if the entity uses a separate tool for managing congestion caused by transactions that originate and/or terminate outside of the entity's service area. This may also be the NERC IDC if used for managing congestion that involves curtailing transactions outside of the entity's service territory.

- Inter-Regional Real-Time Coordination for Market Redispatch — This tool is to adjust the market dispatch within the entity's service territory in coordination with adjacent RCs to manage the inter-regional congestion problem in real time. This tool may be handled by the entity's congestion management application, or it may be handled through a different process.

- Inter-Regional Voltage Profile Coordination. This tool coordinates the voltage profiles between two or more regions. This application may contain features such as wide-area voltage contour visualization, voltage schedule coordination between regions, etc.

- Short-Term Hydro Scheduling. This real-time tool manages deviations from the long-term optimized schedule for reasons of reliability, e.g., a response to a disturbance control standard (DCS) event, acquiring support for localized voltage control, etc.

- Short-Term Wind Energy Forecasting — This near-real-time tool is used to predict and manage generation in response to the variability of supply from wind energy sources.

- Short-Term Load Forecasting — These tools predict short-term (next 0-60 minutes) loads based on parameters such as short-term weather effects, current load, etc. The results from this tool could be used for predictive redispatch, look-ahead contingency analysis, awareness of scheduled non-conforming load changes, etc.

- Short-Term Weather Forecasting — This tool predicts short-term (next 0-60 minutes) extreme weather that may impact operations, i.e. a lightning prediction tool, Doppler radar, etc.

Summary of Findings

The other tools (current and operational) section of the Real-Time Tools Survey was designed to identify tools that provide advanced functionality and are used widely throughout the industry. With the possible exception of congestion management and short-term load forecasting tools, survey results suggest that usage of advanced functions is not prevalent among survey respondents.

The applications described above may provide entities with enhanced situational awareness for monitoring and assessing conditions or performing actions to maintain the reliability of interconnected bulk electric systems. Based on survey results, however, the applications are not used as widely as the typical suite of reliability analysis applications readily available to the industry (i.e., the state estimator or contingency analysis).

Because so few respondents identify themselves as BAs, the task force could not develop statistically significant conclusions for that group. Therefore, the discussion below focuses on RCs and TOPs.

Prevalence of Tools

Table 2.14-1 summarizes responses from RCs and TOPs to survey questions regarding use of advanced tools. For the RCs and TOPs responding, congestion management, short-term weather forecasting and short-term load forecasting were the only applications available to at least 50 percent of respondents. Even though a limited number of overall survey participants responded to questions in this section, the results suggest that these three applications are more prevalently used than the others that were specifically identified.

NOTE: In the columns of all tables in this section that list percentages of respondents, the percentage value is preceded by the number of respondents out of the total that gave the indicated response. For example, “32/38=84%” means that 32 out of a total of 38 respondents, or 84% of respondents, gave the indicated response.

Application	Application Available?			Application Operational?		
	All	RCs	TOPs	All	RCs	TOPs
Congestion management	11/41 = 27%	**7/14 = 50%**	4/24 = 17%	10/13 = 77%	6/8 = 75%	4/5 = 80%
Inter-regional real-time coordination of congestion mgt.	8/38 = 21%	6/13 = 46%	2/22 = 9%	8/9 = 89%	6/6 = 100%	2/3 = 67%
Inter-regional real-time coordination of market redispatch	3/31 = 10%	3/12 = 25%	0/17 = 0%	3/4 = 75%	3/3 = 100%	0/1 = 0%
Inter-regional voltage profile coordination	1/31 = 3%	1/12 = 8%	0/17 = 09%	1/3 = 33%	1/2 = 50%	0/1 = 0%
Short-term hydro scheduling	5/32 = 16%	4/11 = 36%	1/18 = 6%	3/4 = 75%	2/3 = 67%	1/1 = 100%
Short-term wind energy forecasting	1/31 = 3%	0/10 = 0%	1/18 = 6%	1/4 = 25%	0/1= 0%	1/3 = 33%
Short-term load forecasting	13/29 = 45%	**7/9 = 78%**	5/17 = 29%	12/14 = 86%	6/7 = 86%	5/6 = 83%
Short-term weather forecasting	14/30 = 47%	4/10 = 40%	**10/17 = 59%**	14/15 = 93%	4/4 = 100%	10/11 = 91%

Table 2.14-1 — Prevalence of Tools/Applications

Perceived Value of Tools

Although the tools may not be used widely throughout the industry, respondents who report having operational tools tend to rate them “essential” or “desirable” for situational awareness. The tools most widely used are those related to congestion management (see Table 2.14-2). One respondent notes that its congestion management tool is “a key component of our congestion management tool for the Inter-ties and is effective.”

Application	Rated “Essential”			Rated “Desirable”		
	All	RCs	TOPs	All	RCs	TOPs
Congestion management	8/13=62%	6/8=75%	2/5=40%	4/13=31%	2/8=25%	2/5=40%
Inter-regional real-time coordination for congestion management	6/9=67%	4/6=67%	2/3=67%	2/9=22%	1/6=17%	1/3=33%
Inter-regional real-time coordination for market re-dispatch	1/3=33%	1/3=33%	0/0=0%	1/3=33%	1/3=33%	0/0=0%
Inter-regional voltage profile coordination	1/1=100%	1/1=100%	0/0=0%	0/1=0%	0/1=0%	0/1=0%
Short-term hydro scheduling	2/3=67%	2/2 100%	0/1=0%	1/3=33%	0/2=0%	1/1=100%
Short-term wind energy forecasting	0/3=0%	0/1=0%	0/2=0%	3/3 100%	1/1 100%	2/2=100%
Short-term load forecasting	10/14=71%	6/7=86%	3/6=50%	3/14=21%	0/7=0%	3/6=50%
Short-term weather forecasting	5/14=36%	2/4=50%	3/10=30%	9/14=64%	2/4=50%	7/10=70%

Table 2.14-2 — Perceived Value of Tools/Applications

Recommendations for New Reliability Standards

Because the survey responses indicate that the tools addressed in the “other tools” section are not in common usage throughout the industry, RTBPTF does not recommend any new reliability standards or modifications to standards for these tools.

Recommendations for New Operating Guidelines

RTBPTF does not recommend developing any operating guidelines for any of the tools described in this section. The tools are not in common usage throughout the industry so they do not warrant new operating guidelines.

Recommendation – A15

Analyze the need to use tools for congestion management, voltage profiles, wind-energy forecast, and weather forecast.

Areas Requiring More Analysis

In light of findings (with numerous references to voltage control and congestion management) presented in the *Outage Task Force Final Blackout Report*,[81] RTBPTF does recommend further examination of the NERC IDC and other tools for congestion management and tools for inter-regional voltage profile coordination. RTBPTF also recommends further investigation into tools for load forecasting, wind-energy forecasting, and hydro scheduling because it appears that the industry as a whole would benefit from advances in those areas.

Although the task force developed no recommendations for standards or operating guidelines for these tools, some of them, such as those related to congestion management and inter-regional voltage profiles, are gaining wider acceptance. The task force recommends that these tools and areas of application receive additional analysis.

Only 50 percent of the reliability coordinators and 31 percent of others who responded to the survey indicate they use a tool to help manage congestion. All Eastern Interconnection reliability coordinators, however, are required to use the NERC IDC to manage congestion. Several RTO and ISO entities use a security-constrained economic dispatch application to manage internal and inter-regional congestion and use LMP signals to assist with market redispatch. Because the entities that use security-constrained economic dispatch and LMP applications consider them critical to their ability to maintain system reliability, these tools should be researched further to identify the best available tools and practices and to determine whether standards and/or operating guidelines are needed. Additional research also should be performed on other types of congestion management applications that other entity types use.

Only a few respondents indicate that they possess a specific tool for coordinating inter-regional voltage profiles. Many entities doubtless use other tools and processes for this purpose. Given the relevance of voltage profiles to the August 14, 2003, blackout, the industry should perform further research to ascertain the requirements, current availability/development, and feasibility of implementation for tools to coordinate inter-regional voltage profiles.

Only one respondent describes possessing a tool specifically for forecasting short-term supplies of wind energy. Given the increase in wind energy facilities

[81] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April.

across the country, many entities might benefit from such a tool. The industry should research this tool further to ascertain its requirements, current availability/development, and feasibility of implementation.

Industry members more commonly use tools for short-term hydro scheduling and short-term load forecasting than for wind-energy forecasting. As with short-term wind energy forecasting, short-term hydro scheduling and load forecasting can affect the accuracy of results derived from other applications that utilize these data, such as security-constrained economic dispatch and other tools used for reliability analysis. Therefore, the industry should perform additional research into all three of these forecasting tools to identify the tools and practices that achieve the greatest accuracy.

Although most entities probably subscribe to a commercial weather service, a few may have in-house meteorological staff providing this service. Survey results do not indicate the numbers and types of tools used for short-term weather forecasting. In addition, respondents do not specify what actions they take based on weather-forecast data. Because weather forecast data are typically used as input to load-forecasting tools, they can affect the accuracy of those forecasts. The industry should perform additional research on weather-forecasting tools to identify the tools and practices that achieve the greatest accuracy.

Examples of Excellence

RTBPTF identified the following examples of excellence. Each of the entities described below has developed its own method for using some of the tools/applications described in this section.

RTBPTF cites Bonneville Power Administration's use of a curtailment wizard in their implementation of a congestion management application as an example of excellence (See EOE-13 in Appendix E). This wizard is a key component of the congestion management tool for Bonneville Power's interties.

RTBPTF cites as an example of excellence the use of a real power-voltage (PV) stability analysis tool by FE and MISO that determines system operating limits (See EOE-14 in Appendix E). PV analysis is used to determine the health of the system by determining the rate of voltage decay at a system bus as the level of real power changes because of system loads or transfers across the system.

Section 3.0
Situational Awareness Practices

Introduction

The term "situational awareness" is used numerous times in the blackout reports prepared by NERC and the U.S.-Canada Power System Outage Task Force. The term "situational awareness" is often (and perhaps more accurately) referred to as "situation awareness," which has been described as having three levels: level 1 is the perception of elements, level 2 is comprehending what those elements mean, and level 3 is using that understanding to project future states.[1] In the context of the blackout reports, the "situational awareness" of operators fits this same definition: knowing what is going on around you and understanding what needs to be done and when to maintain, or return to, a reliable operating state.

Situational awareness is a key concept mentioned in nearly every section of this report. Sections 3.1 through 3.7 focus on elements of situational awareness related to operating practices and procedures rather than to any particular tool. That is, the subsections of this section of the report address the practices, processes, and procedures used by organizations to ensure that their operators have the information and guidance they need to be aware of potentially unreliable system conditions and know what effective actions they can take to maintain reliability.

Practices Addressed in the Report

In preparation for the design of the Real-Time Tools Survey, the results of which are the basis for this report, RTBPTF reviewed the then-current NERC Reliability Standards to identify elements of situational awareness that were addressed to some extent in the standards. Many of these elements that relate to the use of real-time tools are addressed extensively elsewhere in this report. The situational awareness practices section of the Real-Time Tools Survey covered practices and procedures that were identified for investigation to determine whether specific requirements or guidelines should be defined for them. The intent of the recommendations in the following section is to clarify the standards in a way that is enforceable.

The Real-Time Tools Survey and the subsections below address situational awareness practices:

- **Section 3.1, Reserve Monitoring** — a documented set of procedures, practices, or guidelines for maintaining awareness of the current and near-term reactive reserve capability and operating reserve capability (i.e., capability above firm system demand required to provide for regulation, load

[1] Endsley, M. R. 1988. "Situation awareness global assessment technique (SAGAT)." *Proceedings of the National Aerospace and Electronics Conference (NAECON).* New York: IEEE. pp.789-795.

forecasting error, equipment forced and scheduled outages, and local area protection. It consists of spinning and non-spinning reserve).

- **Section 3.2, Alarm-Response Procedures** — documented instructions for operators to follow when an alarm is issued. These procedures make operators aware of prudent actions to take in an alarm situation. These procedures should not be confused with Operating Guides, which are discussed in Section 3.4, Operating Guides (Mitigation Plans), of this report.
- **Section 3.3, Conservative Operations** — an operational state resulting from intentional actions in response to unknown, insecure, or potentially risky system conditions to move to a known, secure, and low-risk operating posture. For example, the power system is postured differently for an impending hurricane, ice storm, cold front, etc. These practices are primarily proactive and are usually taken in advance of an anticipated event or system condition, as distinguished from reactive practices, such as those discussed in Section 3.6, System Reassessment and Re-posturing. However, conservative operations practices can be employed following some events and can thus be a subset of reassessment and re-posturing.
- **Section 3.4, Operating Guides (Mitigation Plans)** — written procedures or instructions that identify preventive or remedial actions to be taken by operators to mitigate undesirable pre-contingency or post-contingency conditions on the transmission system. Operating guides help operators be aware of the prudent actions to take under various system conditions. Operating guides should not be confused with the procedures discussed in Section 3.2, Alarm-Response Procedures. An operating guide is a situation-specific, proactive mitigation plan for an undesirable pre-contingency or post-contingency condition on the transmission system, as distinguished from an event-specific, reactive response to a specific alarm. In addition, operating guides should not be confused with operating guidelines which are, in the context of this report, prevalent practices of a general nature that are applicable to many reliability entities, as described in the Introduction to this report.
- **Section 3.5, Load-Shed Capability** — documented practices that define how the system operator is kept aware of the status, availability, magnitude, and time to deploy of all load that can be shed on an emergency basis.
- **Section 3.6, System Reassessment and Re-posturing** — documented practices that give guidance to the system operator for returning the system to a secure and studied condition following an event or events that leave the system in an insecure or unstudied state. These practices are primarily "reactive" in that they are usually performed in response to an event, as distinguished from "proactive" practices, such as the conservative operations practices discussed in Section 3.3, Conservative Operations, of this report, which are primarily used in anticipation of an event or system condition. However, conservative operations practices can be employed following

certain events and can thus be a subset of system reassessment and re-posturing.

- **Section 3.7, Blackstart Capability** — documented practices that define how the system operator is to be kept aware of the status and availability of blackstart generating units and transmission paths identified in the system restoration plan as being essential for restoring the system from a blackout. These practices should not be confused with the plans and procedures required by NERC Reliability Standard EOP-005-0, System Restoration Plans. Typically those plans and procedures deal with longer-term issues such as periodic testing of blackstart units and periodic system restoration drills. The specific practices addressed in this section of the report pertain to the near-term or real-time situational awareness of the current state, availability, and capability of the blackstart facilities.

Significance to the August 14, 2003 Blackout

The *Outage Task Force Final Blackout Report* states that NERC Reliability Standards are based on seven key concepts, one of which is emergency preparedness. Organizations need to have a set of plans and procedures in place in advance of any emergency to ensure that operators are aware of the proper course of action to take and capabilities that are available to them when responding to the emergency. The survey questions discussed in Sections 3.1 through 3.7 were designed to determine the availability and usage of the tools, plans, and procedures necessary for responding to significant system events.

For the most part, the necessary "procedures and capabilities" are addressed in the EOP series of NERC reliability standards. However, the *Outage Task Force Final Blackout Report* specifically identifies problems with each of the items identified in Sections 3.1 through 3.7 of this report.

RTBPTF Recommendations for New Reliability Standards

In Sections 3.1 through 3.7, RTBPTF makes several recommendations to add new requirements to existing standards. These recommendations are summarized below.

- RTBPTF recommends that Reliability Coordination — Current Day Operations requirements be revised to delineate specific, independent requirements for monitoring operating reserves and reactive reserves and that specific, independent measures be developed for these requirements.

- RTBPTF recommends that several existing reliability standards be revised and coordinated to include a requirement that each RC and TOP have documented plans and procedures for conservative operations. These plans and procedures shall identify the credible conditions that could lead to an unknown, insecure, or potentially risky operating state and shall identify the appropriate actions operators are expected to take.

- RTBPTF recommends that all existing standards pertaining to mitigating actions shall be coordinated and revised to require that formal operating guides shall be written for each IROL and any SOL or other condition having a potential impact on reliability. When day-ahead or current-day studies indicate the potential for an operating guide to be implemented, the guide shall be reviewed and verified to still be viable given the studied conditions or shall be updated to provide the appropriate guidance.

- RTBPTF recommends standard EOP-003 be revised to require transmission operators and balancing authorities to provide their operators with information sufficient to give them the location, real-time status (in-service or out-of-service), and real-time MWs of load available to be shed via operator-controlled load-shed capabilities. The task force also recommends that standard IRO-005 be revised to require that RCs have the information needed to quickly ascertain the location, time to implement, and available MWs of load that can be shed in response to a directive.

- RTBPTF recommends that NERC Reliability Standard TOP-004-0, Transmission Operations, be revised to include a requirement for each Transmission Operator and Reliability Coordinator to have formal, documented practices and procedures for the reassessment and re-posturing of its system following an event or events that leave the system in an insecure or unstudied state. This recommendation should be considered along with similar recommendations that are made in Section 3.3, Conservative Operations, of this report.

- RTBPTF recommends that requirement R8 of NERC Standard-EOP-005-0, System Restoration Plans, be revised to specifically state that operators be given the information they need to maintain awareness in real time and on a current-day and day-ahead basis of the availability and capability of the blackstart generation resources and transmission cranking paths identified in their system restoration plans. In addition, this requirement should also require that operators be provided documented practices and procedures that identify the specific information to be monitored to ensure the availability and capability of blackstart resources and to identify the actions to be taken in the event that blackstart availability or capability is less than required in the restoration plan.

Section 3.1
Reserve Monitoring

Definition

Reserve monitoring is a documented set of procedures, practices, or guidelines for maintaining awareness of the current and near-term reactive reserve capability and operating reserve capability.[2]

Background

Operating reserves (also known as real or MW reserves) are used to ensure the energy balance for each BA. They tend to globally impact the electrical system, in contrast to reactive reserves, which tend to be more localized. Figure 3.1-1 shows the various types of operating reserve generation that are defined within the NERC Glossary of Terms.[3] Operating reserves consist of both contingency and regulating reserve.

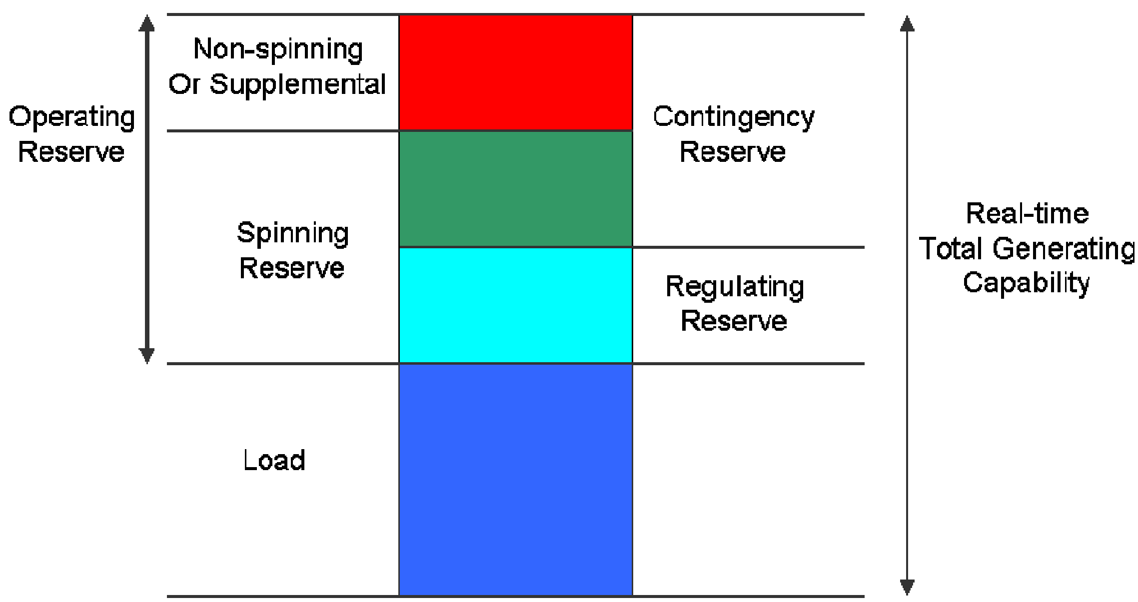

Figure 3.1-1 — Diagram of Reserve Generation, as Defined in NERC Glossary of Terms

---

[2] Defined as the capability above firm system demand that is required to provide for regulation, load forecasting error, equipment forced and scheduled outages, and local area protection. It consists of spinning and non-spinning reserve.

[3] http://www.nerc.com

Summary of Findings

General Questions: Reactive Reserves

The survey results indicate that documented operating practices defining how reactive reserves are monitored are commonly used within the industry. Nearly 63 percent (10 out of 16) of RCs and 52 percent (13 out of 25) of TOPs responding to this section of the survey reported having such procedures. Of the entities that do not currently have documented procedures, most indicate they plan to document reactive reserve practices in the future. This includes all of the remaining RCs and the majority of the remaining TOPs. Of those monitoring reactive reserves, all 10 RCs and 12 of 13 TOPs reported that the function was essential or desirable.

Six respondents took the time to comment on the question of reserve monitoring. Five of those commenting concluded that monitoring reactive reserve levels is essential to ensure proper voltage levels and/or provide inputs to further analysis (PV analysis, analysis of interface limits, voltage stability, etc.) and thus help prevent voltage collapse. One respondent with the capability to calculate reactive reserves operates an ancillary service market for reactive reserve capability that calculates margins.

All RCs and TOPs that have documented practices indicated that control room personnel use them. However, other groups rely heavily on the documented practices, including Operations Support Staff at 60 percent of the RCs and 62 percent of the TOPs, as well as Next-Day Planners at 50 percent of RCs and 31 percent of TOPs who responded. First-line management staff also use the capability, but to a lesser degree (0 percent of RCs and 38 percent of TOPs).

Almost all those reporting (more than 80 percent) indicated that the procedures are published. Some use more than one format to document procedures, as shown in Table 3.1-1.

Documentation Format	RCs	TOPs
EMS Help Systems	40%	15%
Web-based Help systems	30%	0%
Departmental memos/letters	30%	54%
EMS Display Notes	50%	69%
Other	10%	8%

Table 3.1-1 — Documented Practices

A variety of groups were reported as being involved in writing and updating procedures. RCs and TOPs indicated that operations support staff are most heavily involved (100 percent for RCs, 46 percent for TOPs) in documentation of procedures. First-line managers are involved in documenting procedures at 30 percent of RCs and 69 percent of TOPs. Control room personnel and next-day planners are also involved in documentation but to a lesser degree (20 percent at RCs and 38 percent at TOPs). In supplemental comments, one company stated that its EMS vendor is involved in documenting procedures.

A large majority of those reporting (90 percent of RCs, 85 percent of TOPs) reported that procedures are reviewed and updated on an as-needed basis. Forty percent of RCs and 38 percent of TOPs reported that procedures are reviewed annually; no respondents reported reviewing more frequently than once per year. One respondent commented that its procedures are reviewed every 2 years, and another indicated that electronic versions of procedures are updated as needed while hard copies are updated annually.

About 70 percent of RCs and TOPs reported that reactive reserve calculations are performed at SCADA scan rates. Much smaller percentages (0 to 10 percent) reported that calculations of reactive reserves are done weekly, daily or hourly. On-demand triggers are used by 20 percent of RCs and 33 percent of TOPs; event triggers are used by 10 percent of RCs but no TOPs. Forty percent of RCs and 17 percent of TOPs reported that the calculation is initiated for “other” reasons, and several commented that the calculation is performed at the state estimator cycle rate.

The following table shows the responses to the question:

Reactive Reserve Factors	RCs	TOPs
Reactive reserve requirements	50%	33%
Nameplate capabilities of static reactive devices	80%	58%
Voltage-adjusted capabilities of static reactive devices	20%	33%
Design “D-curve” var capabilities of generating units	40%	33%
Field tested and proven var capabilities of gen units	60%	50%
AVR status	50%	33%
Zonal deliverability of reactive reserves	20%	8%
Voltage limits	30%	42%
“n-1” criteria (reserve capability following the next contingency)	20%	42%
In-service/out-of-service status of reactive controllers	50%	50%
static Var compensator (SVC) status	40%	25%
LTC regulating range	0%	42%
SVC operating range	40%	25%
Synchronous condenser capability	50%	8%
Effects of neighboring systems	10%	50%
Others	0%	8%

Table 3.1-2 — Factors considered in the Reactive Reserve Calculation

One of 10 RCs and 4 of 12 TOPs indicate that periodic written reports are used to inform operators of the status of reactive reserves. Some of these respondents indicated that the reports are updated annually. These responses indicate a lack of current, near-term awareness of reactive reserve capability in those control centers. However, the majority reported that dynamically updated displays and/or dashboards are used for operator situational awareness, with multi-purpose “dashboards” used by 70 percent of RCs and 42 percent of TOPs and dedicated displays used by 50 percent of RCs and 67 percent of TOPs. One company uses bar graphs to display unit reactive output and capability and another reports that operators are able to generate detailed reactive capability reports on demand.

The majority of respondents with documented practices indicated that operators are primarily made aware of actual reactive reserve margin deficiencies by audible alarms (56 percent of RCs, 67 percent of TOPs) and by color-coded graphical displays (67 percent of RCs, 33 percent of TOPs). Tabular messages and “other’” mechanisms (nomograms, voltage monitoring on contingencies, voltage alarms, etc.) are used to a lesser extent. No one reported using pop-up messages to make operators aware of reactive reserve margin deficiencies.

Operators are made aware of impending reactive reserve margin deficiencies through a variety of means: audible alarms (11 percent of RCs, 67 percent of TOPs); tabular messages (22 percent of RCs, 25 percent of TOPs); color-coded graphical displays (67 percent of RCs, 33 percent of TOPs); and other means, including nomograms, contingency analysis alarms, voltage alarms at key locations, and notification from RTOs (33 percent of RCs, 42 percent of TOPs). No one reported use of pop-up messages to make operators aware of impending reactive reserve margin deficiencies.

Redispatch (90 percent of RCs, 83 percent of TOPs) and reconfiguration of the electric system (90 percent of RCs, 75 percent of TOPs) were the actions most frequently expected to be taken by operators when, per documented procedures, operators are made aware of reactive reserve margin deficiencies. In addition, 40 percent of RCs and 50 percent of TOPs report that personnel are instructed to change voltage schedules to rectify problems. Several respondents (10 percent of RCs, 25 of percent TOPs) also commented that other operator actions are expected, including load shedding, transformer tap adjustments, switching reactors, and increasing reactive output of units when problems are identified. Small percentages of those responding (10 percent of RCs, 8 percent of TOPs) indicate that no actions would be required unless voltage violations were imminent.

General Questions: Operating Reserves

Of 17 RCs and 25 TOPs responding to the survey questions concerning operating reserves, 88 percent of RCs (15) and 76 percent of TOPs (19) have documented practices defining how operating reserves are monitored. Of those that do not have documented procedures, both RCs and 4 of the 8 (50 percent) TOPs indicated that they planned to document procedures in the future. All 15 RCs that having documented and defined operating reserve monitoring practices indicate that the function is “essential” or “desirable” for situational awareness. Nearly all TOPs (18 of 19) with documented practices defining how operating reserves are monitored rated the value of this practice as “essential” or “desirable” for situational awareness.

Several respondents provided written comments on monitoring operating reserves. The comments indicated that monitoring operating reserves is a “prime resource for system reliability” and should be a requirement for all balancing authorities and “maybe” for TOPs. Other respondents noted:

> “Its one of the most important variables the generator dispatcher must be aware of.”
>
> “…staff needs to know at a glance where operating reserves are available and the amount of reserve available.”

> "Carrying your operating reserves is essential to the reliability of the interconnected transmission system."

Another respondent noted that, in addition to the EMS, operating reserves are tracked by "Market Operation Center web-based reporting tools."

All respondents indicated that control room personnel use operating reserve practices. In addition, about 53 percent of RCs and 33 percent of TOPs reported that next-day planners use the feature. Those reporting also indicate that operations support staff (47 percent of RCs and 61 percent of TOPs) use these practices. More than 30 percent of those reporting indicated that first-line management staff also use the operating reserve practices.

More than 80 percent of those reporting indicate that their operating reserve procedures are published. Some respondents report using more than one format to document procedures, as shown in Table 3.1-3.

Documentation Format	RCs	TOPs
EMS Help systems	20%	22%
Web-based Help systems	27%	17%
Departmental memos/letters	13%	28%
EMS Display Notes	27%	39%
Other	0%	0%

Table 3.1-3 — Formats Used for Documenting Procedures

One respondent clarified that its RTO's written procedures are used for operating reserves.

A variety of groups were reported as involved in writing and updating procedures. RCs and TOPs indicated that operations support staff are most heavily involved (80 percent for RCs, 56 percent for TOPs) in documentation of procedures. First-line management staff are also significantly involved (at 33 percent of RCs and 57 percent of TOPs). Control room personnel are involved in procedure writing and/or updates at only 1 of 15 RCs and 5 of 28 TOPs. Virtually no organizations rely on next-day planners to document operating reserve procedures. Comments reveal that unspecified "reserve groups" or the respondent's RTO or ISO are also involved in documenting operating reserve practices. A large majority of those reporting (100 percent of RCs, 83 percent of TOPs) report that procedures are reviewed and updated on an as-needed basis. Periodic, annual reviews are performed by only 2 of 15 RCs and by 6 of 18 TOPs. No RC reported a periodic review more frequently than once per year; 1 TOP reported a quarterly review/update. One respondent comments that its procedures are reviewed every 2 years.

Eighty percent of RCs and 72 percent of TOPs indicate that operating reserves are calculated at the SCADA scan rate. Smaller percentages of respondents report calculations of operating reserves at less frequent intervals: weekly (7 percent RCs, 0 percent TOPs); daily (13 percent RCs, 11 percent TOPs); and hourly (13 percent RCs, 22 percent TOPs). Additional triggers are also used: on demand (27 percent RCs, 18 percent TOPs); events (13 percent RCs, 6 percent TOPs) and by “others,” such as 4-second, 15-second, 30-second or 5-minute intervals (20 percent RCs, 11 percent TOPs).

Table 3.1-4 illustrates responses to the question regarding which factors are considered in calculating operating reserves.

Operating Reserve Factors	RCs	TOPs
Operating reserve requirements	93%	94%
Seasonal ratings of generating units	60%	61%
Generator reactive loading to maintain voltage schedules	13%	17%
“n-1” criteria (reserve capability following the next contingency)	20%	11%
Historical forced outage rates for generating units	13%	0%
Contributions available from reserve sharing group members	47%	50%
Periodic declared commitments from reserve sharing group members	13%	22%
Firm capacity purchases and sales	47%	78%
Dispatchable load	47%	56%
Quick-start unit capacity	73%	83%
Telemetry	27%	39%
Unit ramp rates	53%	50%
Others	0%	0%

Table 3.1-4 — Factors considered in Operating Reserve Calculation

A clear majority report that operating reserve information is provided to operators via dynamically updated, dedicated displays (73 percent of RCs, 83 percent of TOPs) or dynamically updated, multi-purpose “dashboard” displays for situational awareness (60 percent of RCs, 44 percent of TOPs). Smaller numbers of those responding use periodic written reports (13 percent of RCs, 17 percent of TOPs) to convey information to operators. Only 2 RCs and 1 TOP report using periodic on-line reports. In addition, only 1 RC and 3 TOPs utilize “Other” reporting mechanisms (e.g., SCADA alarms when reserves drop below required levels, unit commitment charts) to convey operating reserve information to operators.

Table 3.1-5 illustrates methods used by the respondents to notify operators of actual deficiencies in operating reserve margins. While tabular messages, pop-up messages and “other” devices are used, operators are most frequently made aware of actual operating reserve margin deficiencies by audible alarms or color-coded graphical displays. The “other” mechanisms used for situational awareness for actual deficiencies include “unit commitment charts,” “online reserve monitors and web based tool …,” “tabular display with color codes,” and “visual indicators on grid wall”). One respondent notes that it has “no alarm, operators monitor,” and another comments that “Alarms” are “under development.”

Table 3.1-5 also illustrates how respondents make operators aware of impending operating reserve margin deficiencies. RCs and TOPs are likely to report impending deficiencies using color-coded graphical displays, “other” means, or tabular messages; audible alarms are not used as extensively as they are to make operators aware of actual operating reserve deficiencies. Pop-up messages are used by only a small percentage of those reporting. “Other” mechanisms for making operators aware of impending operating reserve deficiencies include unit commitment charts, a capacity assessment tool & EMS displays, tabular display with color codes, broadcasts, posted (web) and phone warnings from ISOs, reserve margins, verbal notification, and a periodic manual evaluation process). As above, one respondent reports “No alarm, operators monitor.”

	Actual Operating Reserve Deficiency		**Impending Operating Reserve Deficiency**	
	RCs	**TOPs**	**RCs**	**TOPs**
Audible alarms	47%	61%	8%	35%
Tabular messages	27%	44%	31%	35%
Pop-up messages	7%	17%	8%	12%
Color-coded graphical displays	47%	44%	38%	41%
Others	20%	17%	38%	29%

Table 3.1-5 — Methods of Notifying Operators of “Actual” and “Impending” Operating Reserve Margin Deficiencies

Table 3.1-6 identifies the actions respondents expect operators to take prior to declaring an initial Energy Emergency Alert (EEA-1).The majority of respondents (69 percent of RCs, 89 percent of TOPs) expect operators to recall non-firm sales or redispatch (69 percent of RCs, 67 percent of TOPs) before issuing an EEA-1. Between 30 and 50 percent of RCs and TOPs expect operators to reconfigure the system, enable demand-side management programs for relief, or recall firm sales and/or take other appropriate actions before declaring an EEA-1. Other actions cited in comments included notifying RC and balancing authority; asking for emergency assistance or buying energy in the market; constraining fossil units to maximize total operating reserve; issuing public appeals; sending deployments to bring units on-line; advising various other organizations; constraining generation that has not been offered into the market; requesting voluntary curtailment; curtailing interruptible loads; loading 30 minute (reserves); utilizing all available generation resources; performing supplemental resource evaluations; notifying transmission owners of the possible need for maximum generation; notifying Installed Capacity (ICAP) providers of the possibility of recalling ICAP sales; notifying market participants to activate an emergency demand-response program; and utilizing a reserve-sharing group.

Action	RCs	TOPs
Redispatch	69%	67%
Re-configuration	38%	39%
Recall non-firm sales	69%	89%
Recall firm sales	0%	33%
Demand Side Management	31%	50%
Others	46%	44%

Table 3.1-6 — Actions Operators are Expected to Take Prior to Declaring an EEA-1

Recommendations for New Reliability Standards

Existing NERC reliability standards do not require that operating reserves be calculated or monitored by any entity; entities are only required to have access to and control contingency reserves (BAL-002, R1 and R2) and maintain regulating reserves (BAL-005, R2). RTBPTF recommends that a monitoring requirement be added to the standards to ensure that operators are constantly aware of the available components of operating reserves.

Recommendation – I3

Specify acceptable reactive reserves.

In addition, operating reserves are referenced throughout the standards. In several instances, undefined words are used to refer to a component of operating reserves. This leads to confusion when interpreting the requirements of the standards. Therefore, RTBPTF recommends changes to clarify a term used in the standards.

Recommendation – S16

Require BAs to monitor contingency reserves and calculate contingency reserves at a minimum periodicity of 10 seconds.

RTBPTF Recommendation

To ensure that balancing authorities monitor all of the components of operating reserves, RTBPTF recommends changes to both the contingency and regulating reserve components of the BAL standards. Specifically, RTPBTF recommends that requirement R1 of the BAL-002-0 NERC standard be modified to require that BAs monitor contingency reserves. In addition, the task force recommends a new requirement for the calculation frequency.

PR1. Each Balancing Authority shall ***monitor***, have access to, and/or operate contingency Reserve to respond to Disturbances. Contingency Reserve may be supplied from generation, controllable load resources, or coordinated adjustments to Interchange Schedules.

PR2. Each Balancing Authority shall calculate Contingency Reserves at a minimum periodicity of every 10 seconds.[4]

Recommendation – S17

Revise the current-day operations requirements to delineate specific, independent requirements for monitoring operating and reactive reserves

RTPBTF recommends that requirement R2 of NERC standard BAL-005-0 be modified to require that BAs monitor regulating reserves. In addition, the task force recommends a new requirement for the calculation frequency.

PR3. Each Balancing Authority shall ***monitor*** and maintain Regulating Reserve that can be controlled by AGC to meet the Control Performance Standard.

PR4. Each balancing authority shall calculate Regulating Reserve at a minimum periodicity of every 10 seconds.[5]

[4] To match the update frequency requirement for telemetry data recommended in Section 1.1, Telemetry Data, of this report.

[5] To match the update frequency requirement for telemetry data recommended in Section 1.1, Telemetry Data, of this report.

RTBPTF recommends that requirement R1.4 of IRO-005-2 be modified to refer to Contingency Reserves, to be consistent with the NERC Glossary of Terms.

PR3. System operating (real) and reactive reserves (actual versus required).

Recommendations for Operating Guidelines

Recommendation – G8

Develop a list of the minimum set of items that should be included in the calculations for actual and required operating reserves.

RTBPTF recommends the development of operating guidelines that list the minimum set of items that should be included in the calculations for actual and required operating reserves. These items are listed below:

- Operating reserve requirements
- Facility ratings of generating units (see FAC-008)
- Contributions available from reserve-sharing group members (see BAL-002)
- Firm capacity purchases and sales
- Dispatchable load
- Quick-start unit capacity
- Unit ramp rates

These calculations should be performed at 10-second intervals, and the results should be presented to operators via dynamically updated and dedicated displays, dashboards, or other visualization mechanisms such as those addressed in Section 2.2, Visualization Techniques, of this report.

The task force also recommends that the calculations for actual and required reactive reserves include, at a minimum, the following:

- Nameplate capabilities of static reactive devices
- Field tested and proven var capabilities of generating units
- AVR status
- In-service/out-of-service status of reactive controllers
- Effects of neighboring systems
- Synchronous condenser capability

These calculations should also be performed at 10-second intervals, and the results should be presented to operators via dynamically updated and dedicated displays, dashboards, or other visualization mechanisms, such as those addressed in Section 2.2, Visualization Techniques, of this report.

Areas Requiring More Analysis

RTBPTF did not identify any Areas Requiring More Analysis regarding reserve monitoring.

Examples of Excellence

RTBPTF identified no examples of excellence related to reserve monitoring.

Section 3.2
Alarm-Response Procedures

Definition

Alarm-response procedures are documented instructions that system operators can use to convert alarm data into actionable information. These procedures help system operators know what actions to take in response to a specific alarm.

Background

The *FERC Staff Assessment* identifies a major deficiency in the TOP standards: "While the NERC standards identify the data requirements, they do not identify any minimum acceptable tools and capabilities to turn the data into information necessary to understand critical reliability functions, and therefore the standards lack an important Requirement in this area."[6] This critique applies to many types of system data, but with regard to alarm data, one could argue that alarm-response procedures do convert alarm data into "necessary" information. No NERC reliability standards, however, stipulate specific requirements that would compel RCs, TOPs, or BAs to have documented instructions for operators to follow when an alarm is issued.

Requirement R5 of Standard IRO-002, Reliability Coordination – Facilities, comes close to specifying a requirement for alarm-response procedures when it states that reliability coordinators "shall have monitoring systems that provide information that can be easily understood and interpreted by the Reliability Coordinator's operating personnel, giving particular emphasis to alarm management and awareness systems . . .." The reference to "alarm management," however, indicates that this requirement is best met by utilizing alarm filtering or other processing methods rather than by having a written response procedure for each alarm.

Requirement R6.6 of Standard TOP-004 requires TOPs to have policies and procedures for responding to IROL and SOL violations. Such violations, which are more serious and complex than many of the alarms typically generated in control centers, are best addressed by specific mitigation plans, which this report refers to "operating guides." Alarm-response procedures are not to be confused with operating guides, which are discussed in Section 3.4, Operating Guides (Mitigation Plans), of this report. The recommendations in Section 3.4 address the concerns that FERC staff raised about providing operator guidance for mitigating undesirable pre- or post-contingency conditions on the transmission system.

Alarm Tools (Section 2.1), Alarm-Response Procedures (this section), and Operating Guides (Mitigation Plans) (Section 3.4) are all used extensively throughout the industry.

---

[6] Federal Energy Regulatory Commission (FERC). 2006. *Staff Preliminary Assessment of the North American Electric Reliability Corporation's Proposed Mandatory Reliability Standards*. Page 103. www.ferc.gov/indus-act/reliability/standards.asp.

These complementary tools should be implemented in a coordinated fashion to maximize an operator's situational awareness, standardize and simplify expected operator actions, and facilitate operator access to reference materials that support the decision-making process. In addition to the procedures discussed in the above-listed sections, the alarm-processing methods (such as alarm filtering) discussed in Section 2.1, Alarm Tools, of this report may prove practical in converting alarm data into actionable information. The alarm-response procedures section of the Real-Time Tools Survey evaluates one component of the integrated set of tools an operator should have for converting alarm data into actionable information.

Summary of Findings

Real-Time Tools Survey responses indicate that industry members commonly use alarm-response procedures. More than 70 percent (32 out of 45) of the respondents to this section of the survey report having documented procedures to inform operators of prudent actions to take in an alarm situation. This number includes 63 percent (10 out of 16) of responding RCs. Almost all (31 out of 32) of those who use documented alarm-response procedures find them an "essential" or "desirable" tool for maintaining situational awareness. A few respondents comment on the value of these procedures, for instance: "With the hundreds of alarms that our SCADA and other systems produce, having a useable, understandable alarm procedure is a must."

Another respondent states, "The response to most alarms is fairly straightforward and does not require a specific written procedure. A written procedure is helpful for those few alarms that require the dispatcher to follow through a more complex response, such as arming special protection schemes or initiating curtailment procedures." Only 2 of the 13 respondents that have no documented alarm response procedures report plans to add such procedures, indicating an apparent lack of perceived need for them. Perhaps some entities have more informative ways of displaying alarm data, and perhaps some control centers lack adequate resources for developing and maintaining alarm-response procedures.

Documentation of Procedures

The survey explored the ways in which alarm-response procedures are documented. Nearly all respondents (27 out of 31) retain procedures in the form of published documents. In addition, 58 percent (18 out of 31) have such procedures available via at least one quick-access method such as Web-based help, EMS display notes, or online help systems. Table 3.2-1 summarizes the responses to this question. The results for "online help systems (EMS)" are similar to the results noted in Section 2.1, Alarm Tools, regarding the availability/functionality of help features in the alarm tools application.

Documentation of Alarm Response Procedures	RC1	RC2	RC3	RC4	RC5	RC6	RC7	RC8	RC9	RC10	RC11	RC12	RC13	RC14	RC15	RC16	RC17	Other	Total
Published procedures	X	X	X	X	X	X	X	X	X	X								17	**27**
Online help systems (EMS)						X												6	**7**
Web-based help systems (other)						X	X			X								1	**4**
Departmental memos/letters		X		X			X	X		X								11	**16**
EMS display notes (e. g., notes on substation one-line displays)		X		X		X												9	**12**

Table 3.2-1 — Documentation of Alarm-Response Procedures

Need for Quick Access

Two respondents emphasize the need for quick access to documented procedures. One respondent comments, “Because of the large amount of documentation for reliability coordinators, better use of SCADA reference pages should be explored to allow the operator convenient display of related documents/procedures.” Another respondent expands on this topic, as follows:

> EMS ‘on screen’ procedure identifiers are key examples of best practice operations. Unusual events and conditions requiring operator action are often specific to a particular station, plant, line, etc. Procedure identifiers become ‘quick reference’ tools that assist in precise real-time decision-making. Example: solar magnetic disturbances (SMD) – by utilizing alarm response procedures for a SMD we can view established limits and identify correct actions to be taken to protect specific transformers.

Although this last comment may blur the distinction between alarm-response procedures and operating guides (discussed in Section 3.4, Operating Guides (Mitigation Plans)), it emphasizes the importance of ensuring that guidance is available quickly to operators whenever significant levels of information must be processed under stressful circumstances.

Recommendations for New Reliability Standards

The survey responses do not justify developing a recommendation for a new requirement to mandate a written response procedure for all the types of alarms that can be generated in a control center. As one respondent points out, many alarms can be dealt with in a straightforward manner; documented guidance is helpful only when complex situations arise. In addition to alarm-response procedures, other alarm-processing methods that are discussed in Section 2.1, Alarm Tools, of this report (such as alarm filtering) may prove to be practical ways to convert alarm data into actionable information for operators.

Recommendation – G9

Provide written alarm response procedures via at least one quick access method such as Web-based help or on-line help system.

Recommendations for Operating Guidelines

Based on survey responses, RTBPTF recommends that an operating guideline be developed to encourage providing operators (when requested) with written alarm response procedures that are usable, understandable, and available via at least one quick-access method such as Web-based help, EMS display notes, or an online help system. RTBPTF recommends that the method for accessing the procedures be tied directly to the alarm tools application. That is, when an operator receives an alarm, the alarm entry itself should provide a direct method (e.g., by clicking on an icon on the entry) to access the response procedure pertaining to that alarm.

Areas Requiring More Analysis

RTBPTF identified no areas requiring additional analysis for alarm-response procedures.

Examples of Excellence

RTBPTF identified no examples of excellence for alarm-response procedures.

Section 3.3
Conservative Operations

Definition

Conservative operations encompass actions taken in response to unknown, insecure, or potentially risky system conditions in order to move to a known, secure, and low-risk operating posture. Undertaking conservative operations produces a known, baseline condition in the face of unknown or insecure conditions, thereby enhancing system reliability. Conservative operations produce an operating state in which system operators can be confident and from which they can better focus their preparations for worsening conditions or contingent events. System operators employ conservative operations, for example, to posture a power system in response to an impending hurricane, ice storm, or cold front.

Conservative operating practices are primarily proactive, taken in advance of an anticipated event or system condition, as distinguished from reactive practices such as the reassessment and re-posturing practices described in Section 3.6, System Reassessment and Re-posturing, of this report. Conservative operations practices, however, can be employed following certain events and thus can be a subset of reassessment and re-posturing practices, as noted in Section 3.6.

Background

Requirement R4 of NERC Reliability Standard TOP-004-0, Transmission Operations, states that, "If a Transmission Operator enters an unknown operating state (i.e. any state for which valid operating limits have not been determined), it will be considered to be in an emergency and shall restore operations to respect proven reliable power system limits within 30 minutes." Requirement R5 of NERC Standard TOP-001-0, Reliability Responsibilities and Authorities, requires TOPs to inform their RCs and other affected entities of real-time or anticipated emergency conditions and to take actions to avoid or mitigate those situations. Neither standard establishes performance measures for those requirements or otherwise gives guidance on acceptable compliance. Having documented practices for conservative operations would promote confidence and consistency in the actions operators take to avoid or mitigate threatening conditions or events.

Summary of Findings

Survey results reveal that most respondents have documented practices for identifying and responding to situations that call for initiating conservative operations. Several survey respondents offer testimonials regarding the value of conservative operations practices, such as the respondent who comments that because of such practices, "Consistency among system operators is greatly enhanced." Another respondent states, "It is essential that operators have documented procedures to follow to prepare for impending risky or insecure operating states." One respondent eloquently expresses why conservative operations practices are essential:

> A conservative operation stance puts the system at a known baseline state when there is a high probability of events (or a sequence of events) occurring that are not normally covered by operating within the reliability criteria. Starting at an unstressed, known operating point gives system operators the time to determine what has happened and what actions to take.

Respondents report having documented a range of actions to effect conservative operations. Because there currently is no requirement to have documented practices or procedures for conservative operations, the task force recommends that a subset of the most prevalent and effective procedures uncovered by the survey be formalized into required practices. The new requirement should identify events that call for conservative operations and stipulate the appropriate, event-specific control actions (or means of developing appropriate control actions) for enacting conservative operations.

Documentation of Practices

Most survey respondents report having documented practices for conservative operations. A little more than half of the respondents to this section of the survey (24 out of 46), including 75 percent (12 out of 16) of RC respondents, report having some type of documented practices for identifying conditions under which the system must be moved toward a more conservative operating state and that also describe the actions the system operator is expected to take. Of the respondents who have such documented practices, two-thirds (16 out of 24) consider them "essential" for guiding operator actions. Almost all (23 out of 24) retain such documentation in the form of published procedures. Of the RCs who report having documented practices for conservative operations, 67 percent (8 out of 12) consider them "essential" for situational awareness, and one-third (4 out of 12) consider them "desirable."

A few respondents report other, apparently supplemental, means of documenting practices for conservative operations. Table 3.3-1 identifies the various ways in which respondents document conservative operations practices.

Documentation of Conservative Operations	RC1	RC2	RC3	RC4	RC5	RC6	RC7	RC8	RC9	RC10	RC11	RC12	RC13	RC14	RC15	RC16	Others	Total
Published procedures	X	X	X	X	X	X	X	X	X	X	X	X					11	**23**

EMS display notes (e.g., one-line notes)																	2	**2**

Table 3.3-1 — Documentation of Conservative Operations Practices[7]

Conditions that Trigger Conservative Operations

The survey explored what conditions or events would cause the 24 respondents who report having documented practices to implement conservative operations (see Table 3.3-2). A few RCs report a wide range of triggering events, as do a few TOPs and BAs who are not also RCs. Most respondents identify several triggers, which the task force recommends be included in an operating guideline (see Recommendations for New Operating Guidelines later in this section).

[7] RC responses are indicated with "X." Aliases are used as column headers to mask the RC' names. The aliases in this table are not necessarily consistent with those used in similar tables in this report. That is, "RC 1" in any given table is not the same as "RC 1" or the equivalent identifier in another table in this report.

Conditions Triggering Conservative Operations	RC1	RC2	RC3	RC4	RC5	RC6	RC7	RC8	RC9	RC10	RC11	RC12	RC13	RC14	RC15	Others	Total

Cyber security threats	X	X		X	X											6	**10**
Major loss of load	X				X											7	**9**

Table 3.3-2 — Conditions Triggering Conservative Operations

Documented Actions to be Taken

The survey inquired about what actions are documented as being required or recommended for the system operator to take in response to triggering conditions. The intent of these questions was to determine what is expected of operators when they discover a real-time or potential condition that could cause the system to enter an unknown, insecure, or unreliable operating state. In addition to the tabulated responses summarized in Table 3.3-3, several respondents comment that they take steps to acquire or schedule additional generating capacity and reactive reserves. A few RCs report a wide range of expected operator actions, as did a few TOPs and BAs who are not also RCs. The task force recommends that several of the specific actions that many respondents employ be included in a new operating guideline. As some respondents point out, which actions are appropriate depends on the nature of the current or impending situation.

Table 3.3-3 — Documented Actions for Conservative Operations

Recommendations for New Reliability Standards

Requirement R4 of NERC Reliability Standard TOP-004-0, Transmission Operations, states that a situation in which a TOP “enters into an unknown operating state” is considered an emergency. Requirement R5 of NERC Standard TOP-001-0, Reliability Responsibilities and Authorities, requires TOPs to inform their RC and other affected entities of real-time or anticipated emergency conditions and to take actions to avoid or mitigate those conditions. Neither standard establishes performance measures for those requirements or otherwise provides guidance on acceptable compliance.

Recommendation – S18

Establish document plans and procedures for conservative operations.

RTBPTF Recommendations

The RTBPTF recommends that a requirement be added to Standard TOP-001-0 to address plans and procedures for conservative operations. RTBPTF's first proposed requirement (PR) related to conservative operations is given below.

PR1. Each reliability coordinator and transmission operator shall have documented plans and procedures for conservative operations that identify the conditions that credibly could lead to an unknown, insecure, or potentially risky operating state. The plans and procedures, which shall be made available to the entity's operators, shall identify the appropriate actions operators are expected to take to move the electric system to a known, secure, and low-risk operating posture.

RTBPTF developed the following proposed measure (PM) for the proposed requirement above.

PM1. Each reliability coordinator and transmission operator shall document plans and procedures for conservative operations and shall demonstrate the use of those plans and procedures.

RTBPTF also recommends that requirement R4 of NERC Reliability Standard TOP-004-1 be revised to refer to the plans and procedures proposed in PR1 above and to clarify that it is the transmission system (not the operator) that can actually enter into an unknown (to the operator) operating state. RTBPTF's second PR for conservative operations is as follows:

Recommendation – S19

Restore system operations from an unknown operating state to proven and reliable limits within 30 minutes.

PR2. Any situation in which the transmission system for which a transmission operator is responsible enters an unknown operating state (i.e., any state for which operating limits have not been determined) shall be considered to be an emergency. The transmission operator shall restore system operations to respect proven, reliable limits within 30 minutes. The transmission operator shall restore the system based on the plans and procedures for conservative operations stipulated in PR1 of TOP-001-0.

RTBPTF developed the following PM for the proposed requirement above:

PM2. Whenever the transmission system for which a transmission operator is responsible enters an unknown operating state, that transmission operator shall have and upon request provide evidence such as operator logs, voice recordings or transcripts of voice recordings, electronic communications, alarm program printouts, or other equivalent evidence that can be used to determine whether it restored operations to respect proven, reliable system limits within 30 minutes, in accordance with documented plans and procedures for conservative operations specified in requirement R4.

These recommendations should be considered at the same time as similar recommendations made in Section 3.6, System Reassessment and Re-posturing, of this report.

Rationale

The survey reveals that industry members commonly use documented practices for conservative operations. Current reliability standards that require action in response to an unknown or unreliable operating state lack specificity. The standards should be reinforced by requiring documented practices for conservative operations. Conservative operations produce an operating state in which system operators can be confident and from which they can better focus their preparations for worsening conditions or contingent events. Having documented practices for conservative operations enhances system reliability and promotes consistency in operator guidance and in the actions operators take to avoid or mitigate threatening conditions or events.

Recommendation – G10

Specify the system conditions for initiating conservative operations and action plans to follow during conservative operations.

Recommendations for New Operating Guidelines

The task force recommends that an operating guideline be developed in support of the new requirements for conservative operations proposed above. The operating guideline should stipulate, at a minimum, that the following system conditions should trigger conservative operations:

- Weather events such as severe storms, floods, temperature extremes, or ice (as relevant to the reliability area)

- Natural threats, such as forest fires, volcanoes, or earthquakes (as relevant to the reliability area)
- Terrorist threats or sabotage
- Solar magnetic disturbances (for applicable latitudes)
- Loss of multiple transmission lines, resulting in insecure operations
- Unexpected shortfall in capacity
- Loss of multiple generating units, such as the shutdown of a nuclear plant
- Loss of situational awareness (e.g., major loss of telemetry data or major failure of a critical real-time tool)
- Cyber security threats
- Major loss of load
- Voltage degradation

RTBPTF further recommends that an accompanying operating guideline be developed that, at a minimum, specifies the following operator actions to be taken (as appropriate) if it is necessary to initiate conservative operations.

- Cancel planned outages
- Lower transfer limits
- Increase coordination and communication of relevant information
- Perform analysis of multiple contingencies or other credible disturbances
- Curtail transfers

Alternatively, these operating guidelines may be incorporated in the revised standards recommended above if the standard drafting team and industry response deem that inclusion appropriate.

Areas Requiring More Analysis

RTBPTF recommends no additional areas of analysis for conservative operations.

Examples of Excellence

RTBPTF identified no examples of excellence related to conservative operations.

Section 3.4
Operating Guides (Mitigation Plans)

Definition

Operating guides, also called mitigation plans, are written procedures that identify appropriate preventive or remedial actions that operators should take to mitigate undesirable pre- or post-contingency conditions on the transmission system. An operating guide is a situation-specific, proactive mitigation plan to avoid or repair an undesirable condition, rather than an event-specific, reactive response. Operating guides are vital for providing operators with an understanding (in all appropriate time frames) of the control actions they have available to respond to the types of vulnerabilities and risks that their system studies identify.

Operating <u>guides</u> are not to be confused with operating <u>guidelines</u>, which are, in the context of this report, general practices prevalent at many reliability entities. The NERC glossary defines three other terms that may add to the confusion: operating plan, operating process, and operating procedure. RTBPTF, however, did not find those terms used in any current standards.

Background

Several NERC reliability standards address the need for procedures to direct system operators in mitigating or resolving reliability problems. No standard, however, addresses operating guides in a comprehensive manner that identifies successful control actions. For example, requirement R3 of Standard IRO-005, Reliability Coordination – Current Day Operations, states that RCs are to “initiate control actions or emergency procedures” to resolve IROL violations, but it does not specify a minimally acceptable procedure and even seems to imply that emergency procedures are optional. Neither requirement R3 nor requirement R5 of the same standard, which contains almost identical language, establishes performance measures.

In addition, requirements R6 and R6.6 of Standard TOP-004, Transmission Operations, direct transmission operators to “develop, maintain, and implement formal policies and procedures to provide for transmission reliability,” including “responding to IROL and SOL violations.” Again, however, the requirements neither establish specific performance measures nor identify minimally acceptable procedures.

The *FERC Staff Assessment* notes that the TOP group of standards:

> …does not require that the system be assessed to the same extent in the day ahead planning analysis, nor does it require identification of control actions, implementable within 30 minutes, that are needed to bring the system back to a stable state in order to withstand the next contingency without cascading. This may present a potential vulnerability as operators may not be aware of available control actions or worse may not have control actions, other than firm load

shedding, available to them to adjust the system to a stable state after it incurs its first contingency. This can lead to poor execution and reliability risk after the first contingency has occurred in real-time operations.[8]

This deficiency can be rectified by establishing both appropriate control actions and the time frame in which the system should be assessed to ascertain whether control actions are needed. Requirement R4 of Standard TOP-008, Response to Transmission Limit Violations, addresses time frames somewhat by requiring transmission operators to mitigate SOL violations based on assessments preformed "in all operating time frames." This requirement, however, does not specify whether it applies to day-ahead planning, provides no measures, and does not address control actions or other aspects that the survey found that operating guides tend to include.

Control actions are addressed minimally in requirement R3 of Standard TOP-007, Reporting SOL and IROL Violations. This requirement directs TOPs to "take all appropriate actions" to return the system to within the acceptable bounds of an IROL or SOL. In addition, requirement R4 of this standard directs reliability coordinators to "evaluate actions taken to address an IROL or SOL violation and, if the actions taken are not appropriate or sufficient, direct actions required to return the system to within limits." Both requirements establish only minimal measures, none of which address the need to develop control actions ahead of time and to document expected actions.

Requirement R17 of Standard IRO-005, Reliability Coordination – Current Day Operations, also compels RCs to evaluate the actions taken to return the system to within the acceptable bounds of an IROL. As with requirement R4 of TOP-007, however, requirement R17 neither establishes any measures nor addresses the need to develop control actions ahead of time and document those expected actions.

Standard IRO-004, Reliability Coordination – Operational Planning, comes closest to addressing the deficiency FERC staff identifies in the TOP standards. Requirement R3 of this standard directs RCs to work with TOPs and BAs to "develop action plans that may be required, including reconfiguration of the transmission system, re-dispatching of generation, reduction or curtailment of Interchange transactions, or reducing load to return transmission loading to within acceptable SOLs or IROLs." Although this requirement addresses control actions and applies to day-ahead studies, it neither stipulates performance measures nor addresses the need to document expected actions.

In addressing the context and preconditions for the blackout of August 14, 2003, Chapter 4 of the *Outage Task Force Final Blackout Report*[9] discusses the adequacy of

---

[8] Federal Energy Regulatory Commission (FERC). 2006. *Staff Preliminary Assessment of the North American Electric Reliability Corporation's Proposed Mandatory Reliability Standards*. p. 102. www.ferc.gov/indus-act/reliability/standards.asp

[9] U.S.-Canada Power System Outage Task Force. 2004. Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations. April. Chapter 4.

system studies intended to identify mitigating actions that operators can take to avoid endangering reliability under current-day conditions. Specifically, the report states that:

> Reliability coordinators and control areas prepare regional and seasonal studies for a variety of system-stressing scenarios, to better understand potential operational situations, vulnerabilities, risks, and solutions. However, the studies FirstEnergy relied on—both by FirstEnergy and ECAR—were not robust, thorough, or up-to-date. This left FE's planners and operators with a deficient understanding of their system's capabilities and risks under a range of system conditions.[10]

The report goes on to describe the lack of documented mitigation plans or procedures: "The investigation team could not find FirstEnergy contingency plans or operational procedures for operators to manage the FirstEnergy control area and protect the Cleveland-Akron area from the unexpected loss of the Perry plant."[11]

This section examines operating guides as one component of an integrated set of tools designed to convert data into actionable information. The procedures described in Section 2.1, Alarm Tools, Section 3.2, Alarm-Response Procedures, and the current section are used extensively throughout the industry. As noted in Section 3.2, these complementary tools should be implemented in a coordinated fashion in order to maximize each operator's situational awareness, standardize and simplify expected operator actions, and facilitate access to reference materials that support the decision-making process.

Summary of Findings

The Real-Time Tools Survey results indicate that industry members generally utilize operating guides. Exactly 100 percent (45 out of 45) of the respondents to the operating guides section of the survey report having documented procedures for mitigating undesirable conditions on the transmission system. This number includes 100 percent (16 out of 16) of the responding RCs. More than 82 percent (31 out of 32) of the respondents who report using documented operating guides rate them as "essential" for situational awareness. This number includes 15 of the 16 responding RCs. A few survey respondents offer opinions, generally favorable, regarding the value of operating guides, as demonstrated by the following quotations:

> "Operating guides are a necessary tool to define the limitations of the power system, provide guidance on indications of instability [or] other impending problems, and provide guidance for mitigating actions."

> "Operating guides are necessary for quick and efficient mitigation of operational problems."

[10] Ibid. p. 39.
[11] Ibid. p. 42.

"Operating guides are truly essential to the reliability of the interconnect. Without operating guides, operating decisions in a neighboring area could cause reliability concerns in another area."

Users of Operating Guides

Table 3.4-1 summarizes the types of users of operating guides associated with individual RCs and totals the users associated with all other respondents.

Users of Operating Guides	RC1	RC2	RC3	RC4	RC5	RC6	RC7	RC8	RC9	RC10	RC11	RC12	RC13	RC14	RC15	RC16	RC17	Others	Total
Control room personnel	X	X	X	X	X	X	X	X	X	X	X	X	X	X	X		NR	27	**42**
Next-day planners	X	X	X	X	X	X	X	X	X	X	X	X	X				NR	7	**20**
Operations support staff	X	X	X	X	X		X	X	X								NR	15	**23**
First-line management staff	X	X	X	X	X	X										X	NR	14	**21**
Others	X																NR	1	**2**

Table 3.4-1 — Users of Operating Guides[12]

Writers of Operating Guides

The survey asked who is responsible for writing and updating operating guides. The results, summarized in Table 3.4-2, reveal that the next-day planners associated with RCs are more involved with writing and updating operating guides than is the case for other respondents. Operations support staff and first-line management are heavily involved for all respondents. The involvement of next-day planners in writing operating guides is related to an issue raised in the *FERC Staff Assessment,*[13] which is discussed in depth in the Background subsection above.

---

12 Reliability coordinator responses are indicated with "X." Aliases are used as column headers to mask the RCs' names. The aliases in this table are not necessarily consistent with those used in similar tables in this report. That is, "RC 1" in any given table is not the same as "RC 1" or the equivalent identifier in another table in this report.

13 Federal Energy Regulatory Commission (FERC). 2006. *Staff Preliminary Assessment of the North American Electric Reliability Corporation's Proposed Mandatory Reliability Standards*. www.ferc.gov/indus-act/reliability/standards.asp.

Writers of Operating Guides	RC1	RC2	RC3	RC4	RC5	RC6	RC7	RC8	RC9	RC10	RC11	RC12	RC13	RC14	RC15	RC16	RC17	Others	Total

Control room personnel	X	X				X											NR	9	**12**
Others									X						X		NR	5	**7**

Table 3.4-2 — Writers of Operating Guides

Some respondents indicate that they write or coordinate operating guides in conjunction with various stakeholders, such as market participants. One respondent stated that, “The Security Coordinator actively develops mitigation plans for potential or actual operating events in conjunction with all regional operating entities. All of these plans are discussed on the regional hotline, allowing all regional entities to be involved in and aware of proposed actions in resolving SOL/IROL violations.”

Formats for Operating Guides

The survey explored the various formats in which operating guides are documented. Table 3.4-3 summarizes the responses. The guides of more than 90 percent of respondents to this question (41 out of 45) are in the form of published documents. In addition, approximately 55 percent (25 out of 45) of respondents have operating guides available via at least one quick-access method such as Web-based help, EMS display notes, or online help systems. The need for ready access to operating guides is discussed in the Recommendations for New Reliability Standards subsection below.

Format of Operating Guides	RC1	RC2	RC3	RC4	RC5	RC6	RC7	RC8	RC9	RC10	RC11	RC12	RC13	RC14	RC15	RC16	RC17	Others	Total
Published procedures	X	X	X	X	X	X	X	X	X	X	X	X	X	X	X	X	NR	25	**41**

Others				X													NR	1	**2**

Table 3.4-3 — Format of Operating Guides

Structure of Operating Guides

The survey asked respondents how operating guides are structured. Table 3.4-4 summarizes the responses. A preponderance of respondents (42 out of 45) have specific operating guides that address specific conditions; only about 58 percent of respondents (26 out of 45) have guides for general conditions. Operating guides appear to focus equally on preventive and remedial actions. RCs in particular indicate flexibility in how they structure operating guides.

Structure of Operating Guides	RC1	RC2	RC3	RC4	RC5	RC6	RC7	RC8	RC9	RC10	RC11	RC12	RC13	RC14	RC15	RC16	RC17	Others	Total
Specific guides for specific conditions	X	X	X	X	X	X	X	X	X	X	X	X	X	X	X	X	NR	26	**42**
Generic guides for general categories of conditions	X	X	X	X	X	X	X	X	X	X	X	X			X		NR	13	**26**
Guides focused on preventive actions (pre-contingency)	X	X	X	X	X	X	X	X	X	X	X	X	X	X		X	NR	18	**33**

Table 3.4-5 — Focus of Operating Guides

Documented Actions to be Taken

Key to any operating guide is the set of control actions that it instructs the system operator to take. Table 3.4-6 summarizes survey responses concerning what operator actions the operating guides stipulate. These responses reveal that operating guides contain a wide range of control actions, with most respondents employing the fundamental actions of redispatch, reconfiguration, transaction curtailment, and load shedding.

Documented Actions to be Taken	**RC1**	**RC2**	**RC3**	**RC4**	**RC5**	**RC6**	**RC7**	**RC8**	**RC9**	**RC10**	**RC11**	**RC12**	**RC13**	**RC14**	**RC15**	**RC16**	**RC17**	**Others**	**Total**

Table 3.4-6 — Documented Actions to be Taken

Recommendations for New Reliability Standards

The Real-Time Tools Survey responses reveal that many entities have operating guides that both identify appropriate control actions and are developed and updated based on assessments made in appropriate time frames. There remains, however, a need to formally stipulate performance measures and time frames because, as discussed in the Background subsection of this report, although several NERC reliability standards describe procedures for mitigating or resolving reliability problems, none of them addresses this issue in a comprehensive manner that establishes clear and measurable requirements. The standards fail to specify minimally acceptable procedures or performance measures.

The standards should identify both control actions and the time frame in which the system should be assessed to ascertain whether control actions are needed. Current requirements that address control actions establish, at best, only minimal measures and fail to address the need to develop actions ahead of time and document the expected actions in operating guides. Although requirement R3 of Standard IRO-004, Reliability Coordination – Operational Planning, addresses control actions and applies to day-ahead studies, the requirement stipulates no performance measures and fails to address the need to document expected actions in operating guides.

The standards and requirements described in the Background subsection above should be consolidated and expanded to add clarity, substance, and measurability so that all RCs and TOPs understand they must develop, coordinate, maintain, and implement operating guides that identify preventive or remedial actions to mitigate undesirable pre- or post-contingency conditions on the transmission system.

Operating guides are vital to providing operators with an understanding (in all appropriate time frames) of the control actions available to them to respond to the types of vulnerabilities and risks that adequate system studies can identify.

Recommendation – S20

Develop formal operating guides (mitigation plans) and measures for each IROL and any SOL or other conditions having a potential impact on reliability.

RTBPTF Recommendations

RTBPTF recommends that the following requirements in the NERC TOP reliability standards be consolidated or closely coordinated and cross-referenced in order to clearly, completely, and uniformly spell out all requirements and measures for developing and evaluating control actions to mitigate SOL and IROL violations or other undesirable conditions on the transmission system:

- TOP-004, requirement R3
- TOP-004, requirements R6 and R6.6
- TOP-007, requirements R3 and R4
- TOP-008, requirement R4

In addition, RTPBTF recommends that the following IRO requirements be consolidated or closely coordinated and cross-referenced in order to clearly, completely, and uniformly spell out all requirements and measures for developing and evaluating control actions to mitigate SOL and IROL violations or other undesirable conditions on the transmission system:

- IRO-004, requirement R3
- IRO-005, requirements R3, R4, and R17

RTBPTF further recommends that the consolidated or coordinated requirements be expanded to include the following proposed requirements (PRs):

PR1. Formal operating guides shall be written for every IROL, SOL, or other condition, identified in regional or inter-regional planning studies, seasonal assessments, or other near-term operating studies, that could affect reliability.

Recommendation – S21

Review and update operating guides (mitigation plans) when day-ahead or current day studies indicate the potential need to implement an operating guide.

PR2. When day-ahead or current-day studies indicate the potential need to implement an operating guide, that operating guide shall be reviewed and either verified as still viable for the studied conditions or updated to provide the guidance appropriate to the studied conditions.

Recommendation – S22

Provide temporary operating guides (mitigation plans) with control actions for situations that could affect reliability but that have not been identified previously.

PR3. Temporary, less formal operating guides, which primarily identify control actions, shall be written and provided to operators for situations, identified in day-ahead or current-day studies, that could affect reliability but that have not been identified or formally documented previously.

Recommendation – S23

Develop joint operating guides (mitigation plans) for situations that could require more than one RC or more than one TOP to execute actions

PR4. Operating guides for situations that could require that more than one reliability coordinator direct control actions or more than one transmission operator execute actions shall be jointly developed by all reliability coordinators and transmission operators responsible for directing or executing the control actions.

Recommendation – S24

Develop a formal procedure to document the processes for developing, reviewing, and updating operating guides (mitigation plans).

PR5. A formal procedure shall document the processes for developing, reviewing, and updating operating guides.

Recommendation – S25

Incorporate verifiable and traceable elements such as titles, document numbers, revision numbers, revision history, approvals, and dates when modifying operating guides (mitigation plans).

PR6. Those who modify documented operating guides shall follow a procedure that incorporates verifiable and trackable elements such as titles, document numbers, revision numbers, revision history, approvals, and dates.

Recommendation – S26

Write operating guides (mitigation plans) in clear, unambiguous language, leaving nothing to interpretation.

PR7. Operating guides shall be written in clear, unambiguous language, leaving nothing to interpretation.

Recommendation – S27

State the specific purpose of existence for each operating guide (mitigation plan).

PR8. Each operating guide shall state the specific purpose of (or reason for) its existence.

Recommendation – S28

Summarize the specific situation assessment and address the method of performing the assessment in each operating guide (mitigation plan).

PR9. Each operating guide shall summarize the specific assessment of the situation it addresses including the method of performing the assessment.

PR10. The situations assessed shall include, but are not limited to, the following:

- Violations of thermal limits
- Violations of voltage magnitude limits
- Specific topology configurations
- Conditions that trigger a special protection scheme
- Violations of transfer limits
- Violations of power angle limits

Recommendation – S29

Identify all appropriate preventive and remedial control actions in each operating guide (mitigation plan).

PR11. Operating guides shall identify all appropriate preventive and remedial control actions, including, but not limited to, the following:

- Redispatching on-line generation
- Reconfiguring transmission facilities
- Shedding load
- Curtailing transactions
- Switching shunt reactive devices
- Changing voltage schedules
- Committing or de-committing units
- Arming an SPS
- Changing LTC taps
- Notifying other entities (e.g., reliability coordinators, nuclear stations)
- Changing PAR taps
- Changing control of DC line or FACTS device

Recommendation – S30

Develop criteria in operating guides (mitigation plans) to support decisions regarding whether a specific control action should be taken.

PR12. Operating guides shall include decision-support criteria when operators must decide whether a specific control action should be taken.

Recommendation – S31

Incorporate on-line tools that utilize on-line data when operating guides (mitigation plans) require calculations.

PR13. Operating guides that require the operator to perform calculations shall incorporate online tools that utilize online data.

Recommendation – S32

Make operating guides (mitigation plans) readily available via a quick-access method such as Web-based help, EMS display notes, or on-line help systems.

PR14. Operating guides shall be readily available to operators via a quick-access method such as Web-based help, EMS display notes, or online help systems.

RTBPTF recommends that the following proposed measures (PMs) be established for the requirements presented above.

PM1. Each Reliability Coordinator and Transmission Operator must demonstrate a documented procedure for developing, reviewing, and updating operating guides.

PM2. Each Reliability Coordinator and Transmission Operator must demonstrate the operation of all guides and verify that they include all required elements.

PM3. Each Reliability Coordinator and Transmission Operator must demonstrate that operating guides are readily accessible to on-shift operators.

PM4*.* Each Reliability Coordinator and Transmission Operator must demonstrate how the operator will perform the calculations required for any operating guide.

PM5*.* Each Reliability Coordinator and Transmission Operator must demonstrate the logic of any decision-support criteria in the operating guides.

Rationale

As discussed above, the *Outage Task Force Final Blackout Report*[14] and the *FERC Staff Assessment*[15] both emphasize the need for operators to understand control actions available for mitigating undesirable operating conditions or situations on the transmission system. NERC standards currently identify various vague and uncoordinated requirements for procedures, appropriate actions, and action plans to respond to IROL and SOL violations. A unifying standard applicable to all operating guides will provide structure and clarity regarding performance and compliance with the various requirements. All survey respondents already have documented procedures of some sort to guide the operator in mitigating undesirable conditions on the transmission

[14] U.S.-Canada Power System Outage Task Force. 2004. Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations. April.
[15] Federal Energy Regulatory Commission (FERC). 2006. *Staff Preliminary Assessment of the North American Electric Reliability Corporation's Proposed Mandatory Reliability Standards*. www.ferc.gov/indus-act/reliability/standards.asp.

system. The recommendations and measures proposed above will establish formal, baseline requirements for operating guides that will raise the bar for many reliability entities.

Recommendations for New Operating Guidelines

RTBPTF does not recommend developing operating guidelines for operating guides.

Areas Requiring More Analysis

RTBPTF recommends no additional areas of analysis for operating guides.

Examples of Excellence

RTBPTF identified no examples of excellence related to operating guides.

Section 3.5
Load-Shed Capability

Definition

The Energy Information Administration of the U.S. Department of Energy defines load shedding as the "Intentional action by a utility that results in the reduction of more than 100 megawatts (MW) of firm customer load for reasons of maintaining the continuity of service of the reporting entity's bulk electric power supply system. The routine use of load control equipment that reduces firm customer load is not considered to be a reportable action."[16]

Having the capability to shed electrical load requires knowing the status, availability, magnitude, and time-to-deploy of all load that can be shed on an emergency basis. Operating practices related to awareness of real-time load-shed capability are those documented practices that define how the system operator is kept informed of the status, availability, magnitude, and time-to-deploy of all load that can be shed quickly.

Background

The *Outage Task Force Final Blackout Report* concludes that, had 1,500 MW of load been shed manually or automatically within the Cleveland-Akron area before the outage of the Sammis-Star 345-kV line, the August 2003 blackout could have been averted.[17] In its technical analysis of the blackout, NERC identifies a corrective action to be taken by FE that includes developing the capability to reduce load (by any method or combination of methods) in the Cleveland-Akron area by 1,500 MW within 10 minutes of a directive from FE's RC to do so.[18] To be able to deliver such a response at any time, the TOP must be apprised of the status, availability, magnitude, and time-to-deploy of all load that can be shed by any method or methods. An ongoing awareness of load-shed capability is needed to give all RCs, TOPs, and BAs confidence in their ability to shed load in an emergency situation. Reliability standards, however, do not specify that operators must be given the information needed to maintain situational awareness of their load-shed capability.

NERC Reliability Standard EOP-001-0, Emergency Operations Planning, requires TOPs and BAs to develop, maintain, and implement load-shedding plans. Operators are not, however, required to maintain situational awareness of the probable results of implementing such plans under real-time or developing operating conditions.

NERC Reliability Standard EOP-003-0, Load Shedding Plans, requires TOPs and BAs to have plans for performing operator-controlled, manual load sheds. The standard also requires that

---

[16] http://www.eia.doe.gov/glossary/glossary_l.htm

[17] U.S.-Canada Power System Outage Task Force. 2004. Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations. April. p. 70.

[18] *Technical Analysis of the August 14, 2003, Blackout*: *What Happened, Why, and What Did We Learn?* A report to the NERC Board of Trustees by the NERC Steering Group. July 13 2004. p. 117.

those plans be implementable "in a time frame adequate for responding to the emergency." The standard does not establish a performance measure for this requirement. The *FERC Staff Assessment* found that a major problem with the EOP standards is the failure to specify the amounts and time frames for load shedding capability.[19] FERC staff mentions this deficiency specifically in regard to EOP-003-0[20] and EOP-001-0, about which they state, "load shedding is the option of last resort and must be capable of being implemented in a much shorter time period than 30 minutes."[21] Standards are clearly needed to establish the amounts and time frames for load shedding capability, although those issues are beyond the scope of the Real-Time Tools Survey.

Standard EOP-003-0 also contains requirements pertaining to implementing automatic load shedding via UFLS or UVLS relays, but operators are not required to maintain situational awareness of the availability or effectiveness of those devices or facilities.

Even if requirements regarding amounts and time frames for load shedding capability existed, however, how would an RC know whether the desired response to a directive to shed load could be achieved under real-time operating conditions? And how would the TOP or BA know that it could respond adequately to such a directive? NERC standards give RCs the authority to direct TOPs and BAs to shed load, and those entities are required to comply with such directives. Currently, however, no standards require any of the entities to maintain awareness of their capabilities to shed load under real-time operating conditions.

Summary of Findings

The load-shedding capability section of the Real-Time Tools Survey was intended to assess current operator practices related to maintaining awareness of load-shed capability and ability to utilize that capability in an emergency. Although most survey respondents report having documented practices for maintaining awareness of load-shed capability, the information they monitor varies greatly, as do the actions identified for shedding load. In addition, few respondents report monitoring any aspect of situational awareness of automatic load-shedding devices, either UVLS or UFLS relays.

Documentation of Practices

Survey respondents generally have documented practices for maintaining awareness of load-shed capability. Approximately 74 percent of respondents (34 out of 46) report having some type of documented practices for this function. Of those who have documented practices, more than 66 percent (23 out of 34) consider them "essential" to situational awareness. Current load-shed capability appears to be documented most thoroughly among TOPs,

[21] Ibid. p. 50.

including the RCs who are also TOPs, probably because in most situations only the TOP has direct control over load-shed capability. Table 3.5-1, identifies the types of documentation respondents have regarding their load-shed practices.

Documentation of Load-Shed Practices	**RC1**	**RC2**	**RC3**	**RC4**	**RC5**	**RC6**	**RC7**	**RC8**	**RC9**	**RC10**	**RC11**	**RC12**	**RC13**	**RC14**	**RC15**	**RC16**	**Others**	**Total**

Table 3.5-1 — Documentation of Load-Shed Practices[22]

Load-Shed Information Monitored

The survey explored ways in which system operators keep informed of the status of factors related to their load-shed capability (see Table 3.5-2). As a whole, respondents who are TOPs appear to monitor a wide range of information, as do RCs who are also TOPs and 2 RCs who are not TOPs. One RC reports that its system operators monitor the sensitivity factors of load-shed capability on any facilities that are in violation of thermal, reactive, or transfer limits. A few RCs report a much narrower scope of monitored information, and some did not respond to this question.

Load-Shed Information Monitored	**RC1**	**RC2**	**RC3**	**RC4**	**RC5**	**RC6**	**RC7**	**RC8**	**RC9**	**RC10**	**RC11**	**RC12**	**RC13**	**RC14**	**RC15**	**RC16**	**Others**	**Total**

Calculated or estimated cold-load pickup of shed load			X														4	**5**
Calculated or estimated load recovery rates following a voltage reduction										X							8	**9**

Table 3.5-2 — Load-Shed Information Monitored

In response to survey questions related to automatic load shedding, only 5 RCs report monitoring any aspect of UFLS relays. Three RCs monitor the status, location, and set points of UFLS relays, and 4 monitor, in one manner or another, the amount of load subject to UFLS operations. RCs report monitoring even fewer aspects of UVLS relays. Perhaps these RCs have few (or no) UVLS relay schemes in their reliability areas.

Similarly, few entities who are not RCs (that is, TOPs, BAs, or other respondents) report that their system operators monitor situational capability of UFLS relays. Only 10 respondents report that their operators monitor the status, location, and set points of UFLS relays. Similarly, only 10 respondents monitor, in one manner or another, the amount of load subject to UFLS operations. To put the awareness of UFLS relays into perspective, fewer than half of all respondents (26 out of 55) provide responses to the UFLS relay question, and only about half of those who respond report that their system operators monitor anything related to UFLS relays.

Documented Actions to Be Taken

The survey asked what documented actions system operators are expected to take when load-shed capability is inadequate. These questions were intended to identify what operators are expected to do when they realize (before load shed is needed) that a current lack of available resources or facilities will prevent operator-controlled load-shedding schemes from yielding the hoped-for results. Table 3.5-3 summarizes the responses. The low number of responses might indicate that, industry wide, this issue has not been given much consideration. A few respondents make comments to the effect that if load shed were implemented and the desired results were not achieved, then an attempt would be made to shed additional load.

Expected Actions for Inadequate Load-Shed Capability	RC1	RC2	RC3	RC4	RC5	RC6	RC7	RC8	RC9	RC10	RC11	RC12	RC13	RC14	RC15	RC16	Others	Total

Table 3.5-3 — Expected Operator Responses to Inadequate Load-Shed Capability

Recommendation – I4

Determine adequate load-shed capability.

Recommendations for New Reliability Standards

All RCs, TOPs, and BAs need confidence in their ability to shed load in an emergency situation, which means they need to be continuously aware of their load-shed capability. Reliability standards, however, do not specify that operators must be given the information needed to maintain situational awareness of load-shed capability.

As noted in the Background section above, NERC Reliability Standard EOP-001-0, Emergency Operations Planning, requires TOPs and BAs to develop, maintain, and implement load-shedding plans. There is, however, no requirement for operators to maintain situational awareness of the probable results of implementing the plans under current or developing operating conditions. In addition, NERC Reliability Standard EOP-003-0, Load Shedding Plans, requires TOPs and BAs to have plans for operator-controlled, manual load shed. The standard requires that these plans be capable of being implemented "in a timeframe adequate for responding to the emergency." The standard, however, does not specify a measure for this requirement.

NERC standards currently assign RCs the authority to direct their TOPS and BAs to shed load, and TOPs and BAs must comply with such directives. No standard, however, specifies that any of these entities must maintain awareness of their capability to shed load under current operating conditions.

Standard EOP-003-0 also contains requirements pertaining to plans for implementing automatic load shedding via UFLS or UVLS relays but does not specify the need for operator awareness of the status of the devices or facilities supporting those plans.

The lack of specific load-shedding directives should be addressed by new requirements in the EOP group of reliability standards.

Recommendation – S33

Provide the location, real-time status, and MWs of load available to be shed.

RTBPTF Recommendation

The RTBPTF recommends that requirements be added to Standard EOP-003-0 to address operator awareness of current load-shedding capability. RTBPTF's proposed requirements (PR) related to load-shedding capability are as follows:

PR1. Each transmission operator and balancing authority shall provide their operators with information sufficient to give them the location, set points, real-time status (in service or out of service), and actual MW of load-shed capability (measured, calculated, or estimated) from the automatic load-shedding schemes (UFLS or UVLS relays) that are installed within the transmission operator's or balancing authority's footprint.

PR2. Each transmission operator and balancing authority shall provide their operators with information sufficient to give them the location, real-time status (in service or out of service), and real-time MW of load available to be shed via the operator-controlled load-shedding capabilities (including voltage reduction) that they are required to be able to implement within an “adequate” time frame.

RTBPTF developed the following proposed measures (PMs) for the proposed requirements above.

PM1. Each transmission operator shall demonstrate via documented procedures, real-time visualization tools, or other dynamically updated media readily accessible to operators, the static and dynamic information provided to operators to fulfill requirement PR1.

PM2. Each transmission operator shall demonstrate via documented procedures, real-time visualization tools, or other dynamically updated media readily accessible to operators, the static and dynamic information provided to operators to fulfill requirement PR2.

Requirement R3 of NERC Standard IRO-005-0, Reliability Coordination – Current Day Operations, stipulates that RCs must “ensure [that] all resources, including load shedding, are available to address a potential or actual IROL violation.” The standard contains no performance measures for this requirement. Because RCs have the authority and responsibility to direct (and ensure the availability of) load shedding, they also should be continuously aware of the number of MW that they can expect will be shed as a result of their directives to shed load by operator-controlled actions, including voltage reduction. In addition, they should be aware of the expected performance of UFLS or UVLS relays in response to abnormal system conditions. The most effective way to ensure this awareness would probably be to delegate responsibility for it to the TOPs and BAs, who would then keep the RC informed.

RTBPTF recommends that a requirement be added to Standard IRO-005-0 to address the need to keep RCs informed of load-shedding capabilities.

PR3. Each reliability coordinator shall be able to ascertain quickly, using information provided by the transmission operators and/or balancing authorities in their footprint (or by other means), the location, time to implement, and available MW of load that can be shed in response to a directive or that can be expected to be shed as a result of an abnormal system frequency or voltage event. Updates should be prepared at a minimum on a by-exception basis, and verifications should be performed at least daily.

RTBPTF recommends the following measure for PR3.

PM3. Each reliability coordinator shall have documented procedures for ascertaining the current load-shed capability of the transmission operators and balancing authorities in his area of responsibility. The reliability coordinator shall maintain a log of the updates made to the information regarding load-shed capability and the verification of that information.

Rationale

Reliability standards related to load-shedding capability are vague and lack specific requirements for providing operators with the information they need to maintain awareness of their load-shed capability under current and developing system conditions. Standard IRO-005, for example, requires RCs to “ensure” the availability of load shedding. This requirement is unachievable unless RCs maintain situational awareness sufficient to engender ongoing confidence that a directive to shed load can be fulfilled. Standard EOP-003 requires transmission providers and BAs to have the capability to shed load in an “adequate” time frame. This requirement is unachievable unless operators have sufficient situational awareness to engender ongoing confidence that they can respond successfully to a directive to shed load.

Many factors underscore the need for the requirements and measures recommended above. These include the failure to take proactive steps to shed load to avert the blackout of August 14, 2003, the FERC staff’s assessment that requirements are needed for the amounts and timing of load-shedding capability, the vague load-shed requirements in the reliability standards, and the findings of the Real-Time Tools Survey.

Recommendations for Operating Guidelines

RTBPTF does not recommend developing operating guidelines for awareness of real-time load-shed capability.

Areas Requiring More Analysis

RTBPTF identified no areas requiring additional analysis for awareness of load-shedding capability.

Examples of Excellence

RTBPTF cites a load-shedding/rotation and voltage reduction application used by Dominion Virginia Power as an example of excellence (See EOE-15 in Appendix E). This application enhances reliability and situational awareness by allowing quick response to a load-shed directive and overview monitoring of load shed facility availability and expected response.

Section 3.6
System Reassessment and Re-posturing

Definition

Reassessment and re-posturing of an electrical transmission system entail control actions that return the system to a secure and studied condition following one or more events, such as an overload, that place the system in an insecure or unstudied state. Control actions associated with reassessment and re-posturing of a system include identifying, evaluating, and correcting. Documented operating practices related to reassessment and re-posturing of a system are primarily reactive in that they usually are performed in response to an event.

Reassessment and re-posturing should be distinguished from proactive practices, such as the conservative operations practices discussed in Section 3.3, Conservative Operations, of this report, which are used primarily in anticipation of an event or system condition. Because conservative operations practices can also be employed following certain events, however, they can form a subset of practices related to reassessment and re-posturing of a system, as indicated in Table 3.6-2 below and in the subsequent recommendations.

Background

Chapter 7 of the *Outage Task Force Final Blackout Report* includes an examination of causal factors common to all major outages during the past 40 years.[23] One cause common to several events (including the August 14, 2003 blackout) is that some operators performed "no reassessment of system conditions following the loss of an element and [no] readjustment of safe limits."[24] The report goes on to repeat the following recommendation from past events: "Following a contingency, the system must be returned to a reliable state within the allowed readjustment period. Operating guides must be reviewed to ensure that procedures exist to restore system reliability in the allowable time periods."[25]

The current NERC reliability standards closely related to this recommendation are limited in scope and specificity. Some fail to address reassessment and readjustment, and others fail to require documentation of necessary procedures.

Requirement R6 of NERC Reliability Standard TOP-004-0, Transmission Operations, requires that TOPs have formal policies and procedures that provide for transmission reliability. Several subrequirements of R6 identify the activities those policies and procedures should address, but none specifically includes the reassessment and re-posturing of a system following an event or events that leave the system in an insecure

[23] U.S.-Canada Power System Outage Task Force. 2004. Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations. April. pp. 107–110.
[24] Ibid. p.108.
[25] Ibid.

or unstudied state. Although subrequirement R6.6 comes close, it refers only to responding to IROL or SOL violations. Other situations may require a system to be reassessed or re-postured. For example, requirement R4 of Standard TOP-004-0, Transmission Operations, states that a situation in which a generating or transmission facility “enters into an unknown operating state” is to be considered an emergency, and operations must be restored “to respect proven reliable power system limits within 30 minutes.” This requirement, however, does not specify the need for documented procedures.

Requirement R17 of NERC Standard IRO-005-1, Reliability Coordination—Current Day Operations, requires RCs to evaluate the impacts of an SOL or IROL violation and decide whether the actions being taken are appropriate and sufficient. Of all the requirements in this standard, R17 comes closest to addressing reassessment and re-posturing, but its scope is limited to SOL and IROL violations. It also does not require that RCs have documented practices or procedures for the prescribed evaluations and determinations. This deficiency in the IRO standard is the same as the one discussed above in relation to the TOP standards.

The *FERC Staff Assessment* notes that the TOP group of standards:

> …does not require identification of control actions, implementable within 30 minutes, that are needed to bring the system back to a stable state in order to withstand the next contingency without cascading. This may present a potential vulnerability as operators may not be aware of available control actions or worse may not have control actions, other than firm load shedding, available to them to adjust the system to a stable state after it incurs its first contingency. This can lead to poor execution and reliability risk after the first contingency has occurred in real-time operations. [26]

Summary of Findings

The reassessment and re-posturing section of the Real-Time Tools Survey evaluates the prevalence and types of documented actions to be taken to reassess and re-posture a system following an event or events that render it insecure or unstudied. Survey results reveal that a majority of respondents have documented practices related to reassessing and re-posturing their systems. The results also reveal that respondents have documented a range of actions for reassessing and re-posturing the system.

Documentation of Practices

The survey responses reveal that industry members generally possess documented practices for reassessment and re-posturing of their systems. Approximately 61

[26] Federal Energy Regulatory Commission (FERC). 2006. *Staff Preliminary Assessment of the North American Electric Reliability Corporation’s Proposed Mandatory Reliability Standards*. www.ferc.gov/indus-act/reliability/standards.asp. p.102.

percent of respondents to this section of the survey (28 out of 46), including 88 percent (14 out of 16) of the RCs who responded, report having some type of documented practices that guide the operator in reassessing and re-posturing the system.

More than 78 percent (22 out of 28) of those who have documented practices consider them “essential” for guiding operator actions and maintaining system reliability. Of the RCs who report having such documented practices, 93 percent (13 out of 14) consider them “essential” for situational awareness and the remaining RC considers them “desirable” for situational awareness. These results represent an impressive endorsement of the necessity for these practices.

All respondents who have documented practices (28 out of 28) have them in the form of published procedures. A few report one or more other, apparently supplemental, means of documenting practices for reassessing and re-posturing the system. Table 3.6-1 identifies the ways in which practices are documented.

Documentation of Reassessment and Re-posturing Practices	**RC1**	**RC2**	**RC3**	**RC4**	**RC5**	**RC6**	**RC7**	**RC8**	**RC9**	**RC10**	**RC11**	**RC12**	**RC13**	**RC14**	**RC15**	**RC16**	**Others**	**Total**
Published procedures	X	X	X	X	X	X	X	X	X	X	X	X	X	X			14	**28**

Online help systems (EMS)	X	X															2	**4**
EMS display notes (e.g., one-line notes)	X																3	**4**

Table 3.6-1 — Documentation of Reassessment and Re-posturing Practices[27]

Several respondents’ comments indicate that entities employ various methods for categorizing and presenting these practices. In several control centers, the practices are incorporated into various separate but related procedures rather than being captured in a single procedure or set of procedures specific to the topic. More than 90 percent of respondents (26 out of 28) report having specific guides for specific conditions, and more than two-thirds (19 out of 28) report having generic guides for general categories of conditions. Seventeen respondents have both. Half of the respondents (14 out of 28) indicate that their documented guides are in the form of checklists of actions to be taken. How the documentation is structured or categorized may not be important, but the necessity of having such documentation is summed up by one respondent as follows: “Guidance and procedures for calculating new reliable

[27] Reliability coordinator responses are indicated with “X.” Aliases are used as column headers to mask the RCs’ names. The aliases in this table are not necessarily consistent with those used in similar tables in this report. That is, “RC 1” in any given table is not the same as “RC 1” or the equivalent identifier in another table in this report.

operating limits, redispatch of generation, communication and notification, etc., are necessary when operators [are] assessing and responding to unplanned events."

Documented Actions to be Taken

The survey also inquired about the tasks, functions, or other actions specified in the documented practices of the 28 respondents who report having them. Table 3.6-2 summarizes the responses. Some RCs report having a comprehensive set of documented actions, as do some TOPs and BAs who are not also RCs. Several actions that are taken by a majority of respondents should be included in an operating guideline for the industry as a whole.

Documented Actions for Reassessment and Re-posturing	RC1	RC2	RC3	RC4	RC5	RC6	RC7	RC8	RC9	RC10	RC11	RC12	RC13	RC14	RC15	Others	Total

Recommendations for New Reliability Standards

Because there currently is no requirement for documented practices or procedures related to reassessment and re-posturing, RTBPTF recommends that a subset of the most prevalent and appropriate procedures revealed by the Real-Time Tools Survey be formalized into required practices.

As noted in the Background subsection above, the *Outage Task Force Final Blackout Report* underscores that, "Following a contingency, the system must be returned to a reliable state within the allowed readjustment period. Operating guides must be reviewed to ensure that procedures exist to restore system reliability in the allowable time periods"[28] and the current NERC reliability standards that closely relate to this recommendation either fail to address reassessment and readjustment or fail to require documentation of necessary procedures. Requirement R17 of NERC Standard IRO-005-1, Reliability Coordination – Current Day Operations, comes closest to addressing reassessment and re-posturing, but its scope is limited to SOL and IROL violations, and it does not require documented practices or procedures. The FERC Staff Assessment also calls for documented practices and procedures for reassessing and re-posturing a system.

Recommendation – S34

Establish documented procedures for the reassessment and re-posturing of the system following an event.

RTBPTF Recommendations

RTBPTF recommends that NERC Reliability Standard TOP-004-0, Transmission Operations, be revised to include a requirement that each transmission operator and reliability coordinator have formal, documented practices and procedures for the reassessment and re-posturing of the system following an event or events that leave the system in an insecure or unstudied state. RTBPTF further recommends that NERC Standard IRO-005-1, Reliability Coordination—Current Day Operations, be revised to include a requirement that reliability coordinators have formal, documented practices and procedures to evaluate whether the actions being taken by transmission operators are effective responses to the event or events that left the system in an insecure or unstudied state. These documented practices should also address appropriate control actions if the evaluation indicates that the transmission operator's response is ineffective or insufficient. The goal of these practices is to help operators identify appropriate control actions (or means of developing appropriate control actions) for reassessment and re-posturing of the system.

RTBPTF recommends that the requirement below be added to Standard TOP-004-0 to establish procedures for reassessment and re-posturing of the system following an event or events that place the system in an insecure or unstudied state. This recommendation should be considered along with similar recommendations made in Section 3.3, Conservative Operations, of this report. RTBPTF's proposed requirement (PR) related to reassessment and re-posturing of a system is as follows:

PR1. Each reliability coordinator and transmission operator shall create and maintain formal, documented practices and procedures for the reassessment and re-

[28] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April. p. 108.

posturing of its system following an event or events that leave the system in an insecure or unstudied state.

RTBPTF developed the following proposed measure (PM) for the proposed requirement above:

PM1. Each reliability coordinator and transmission operator shall demonstrate the performance of its documented practices and procedures for the reassessment and re-posturing of its system by conducting a simulation of an event that leaves the system in an insecure or unstudied state or by providing operator logs and other records and reports of actions taken following an actual event.

RTBPTF also recommends that a new requirement be added to Standard IRO-005-1 to address the RC's reassessment of the system.

PR2. Each reliability coordinator shall create and maintain formal, documented practices and procedures related to reassessment of its system to evaluate the appropriateness of the actions being taken by transmission operators in the reliability coordinator's footprint following an event or events that leave the system in an insecure or unstudied state. These documented practices and procedures shall also address appropriate control actions or re-posturing of the system in case the reliability coordinator's evaluation indicates that the transmission operator's actions are inappropriate or insufficient.

PM2. Each reliability coordinator shall demonstrate the performance of its documented practices and procedures for evaluating whether the actions being taken by transmission operators in the reliability coordinator's footprint are appropriate by conducting a simulation of an event that leaves the system in an insecure or unstudied state or by providing operator logs and other records and reports of actions taken in response to an actual event.

Rationale

Failure to adequately reassess and re-posture the transmission system following contingency events has been one of the causes common to several major, historical outages, including the blackout of August 14, 2003. The proposed recommendations above, which will add scope and specificity to current reliability standards, are necessary to provide operators with the information and guidance they need to perform reassessment and re-posturing. The *FERC Staff Assessment* of the TOP series of standards supports these recommendations. The Real-Time Tools Survey findings establish that documented procedures for reassessing and re-posturing the transmission system following a contingency event are prevalent within the industry. The recommendations proposed above will establish formal, uniform requirements for documented and demonstrable practices and procedures that will raise the bar for many reliability entities.

Recommendation – G11

Communicate and coordinate with neighboring systems for reassessing and re-posturing a system following an event that places the system in an insecure or unstudied state following an event that places the system in an insecure or unstudied state.

Recommendations for Operating Guidelines

RTBPTF recommends that an operating guideline be developed in support of the new requirements recommended above for reassessing and re-posturing the electric system. At a minimum, the following tasks, functions, and other actions should be included in the recommended policies and procedures:

- Communication and coordination with neighboring systems
- Verification of situational awareness
- Conservative operations (discussed in Section 3.3, Conservative Operations, of this report)
- Verification of data availability
- Verification of tool availability
- Reassessment, recalculation, or reverification of SOLs
- Reassessment, recalculation, or reverification of IROLs
- Identification of appropriate control actions or specific methodologies for developing appropriate control actions

Alternatively, this operating guideline may be incorporated in the revised standards recommended above if the standard-drafting team and industry deem that inclusion appropriate.

Areas Requiring More Analysis

RTBPTF identified no areas requiring additional analysis for system reassessment and re-posturing.

Examples of Excellence

RTBPTF cites the development of documented guidelines to address events on the transmission system that are outside the scope of established operations by the Virginia Carolinas (VACAR) South Subregion of SERC Reliability Corporation (SERC) as an example of excellence (See EOE-16 in Appendix E). These guidelines, which are part of the *VACAR-South Reliability Coordinator Handbook*, are intended for use by the RC working in close coordination with the BAs (TOPs) within the reliability area, and includes several examples of what to include in a procedure for reassessing and re-posturing the system following an event or events that leave the system in an insecure or unstudied state.

Section 3.7
Blackstart Capability

Definition

Blackstart generators can operate without an external power source. They are designed to provide power to critical transmission pathways after a blackout so that other critical generators can be restarted. Operating practices related to blackstart capability define how a system operator maintains awareness of and responds to the condition of blackstart generating units and transmission paths identified in the system restoration plan as being essential for restoring power after a blackout.

Background

The *Outage Task Force Final Blackout Report* states that, "to deal with a system emergency that results in a blackout,…there must be procedures and capabilities to use 'black-start' generators (capable of restarting with no external power source) and to coordinate operations in order to restore the system as quickly as possible to a normal and reliable condition."[29] NERC Reliability Standard EOP-005-0, System Restoration Plans, requires each TOP to have a plan for re-establishing its electric system in the event of a partial or total shutdown. Among other things, restoration plans must evaluate the reliable capability of blackstart generation resources and the "cranking" transmission paths needed to deliver those resources to other generating units, which will be started subsequently in accordance with the restoration plan. Most of the requirements of this standard concern long-term activities such as annual review and update of the plan, periodic testing, and annual simulation.

The standard contains a requirement (R8) that each TOP shall "ensure the availability and location of blackstart capability within its area to meet the needs of the restoration plan." Although this requirement does not specify the time frame to which it applies, an argument can be made that it must apply to near-term or real-time awareness of the condition of blackstart facilities. It stands to reason that, once having identified blackstart generation resources and key transmission paths, TOPs must not inadvertently compromise their ability to implement system restoration plans by neglecting to maintain day-ahead, current-day, or real-time awareness of the condition of the blackstart facilities.

The practices examined here are not to be confused with practices required by NERC Reliability Standard EOP-005-0, System Restoration Plans. These NERC practices generally concern long-term activities such as periodic testing of blackstart units and periodic system restoration drills. The practices addressed in this section pertain to near-term or real-time awareness of the state, availability, and capability of a system's blackstart facilities.

---

[29] U.S.-Canada Power System Outage Task Force. 2004. Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations. April. p.10.

The blackstart capability section of the Real-Time Tools Survey addresses the prevalence of and methods for documenting and monitoring real-time blackstart conditions and responding to a lessening or loss of blackstart capability.

Summary of Findings

Survey respondents generally have documented practices regarding blackstart capability, but it is clear from the survey results that more specific guidance and requirements are needed in this area.

Documentation of Monitoring Practices

Survey responses reveal that industry members generally possess documented practices for maintaining awareness of blackstart capability. Approximately 63 percent of respondents (27 out of 43) report having documented practices for maintaining awareness of blackstart capability. This figure includes 75 percent (12 out of 16) of RCs who responded. More than 80 percent (23 out of 27) of those who have documented practices consider them “essential” for situational awareness. This figure includes 69 percent (11 out of 16) of the responding RCs.

All (27 out of 27) those with documented practices have them in the form of published procedures. Table 3.7-1 identifies the types of documentation that respondents maintain monitoring blackstart capability.

Documentation of Procedures for Monitoring Blackstart Capabilities	RC1	RC2	RC3	RC4	RC5	RC6	RC7	RC8	RC9	RC10	RC11	RC12	RC13	RC14	RC15	RC16	Others	Total

Table 3.7-1 — Documentation of Procedures for Monitoring Blackstart Capabilities[30]

Information Monitored

The survey inquired about the specific information that operators monitor in order to maintain awareness of current blackstart capabilities. Table 3.7-2 summarizes the responses. All but 2 of the respondents included in the "Others" column of the table represent TOPs. The responses summarized in this column indicate that TOPs monitor a wide variety of information, as do many RCs who are also TOPs. It may be that TOPs monitor such a wide range of information because, in most cases, only the TOP has direct responsibility for and control over a system restoration plan that utilizes blackstart generation to energize key transmission paths. Several RCs report monitoring a narrower scope of information, and others did not respond to this question.

---

[30] Reliability coordinator responses are indicated with "X." Aliases are used as column headers to mask the RCs' names. The aliases in this table are not necessarily consistent with those used in similar tables in this report. That is, "RC 1" in any given table is not the same as "RC 1" or the equivalent identifier in another table in this report.

Blackstart Information Monitored	RC1	RC2	RC3	RC4	RC5	RC6	RC7	RC8	RC9	RC10	RC11	RC12	RC13	RC14	RC15	Others	Total
On-line/off-line status of blackstart units	X	X	X	X	X	X	X	X	X	X	X					20	**31**
Scheduled return-to-service dates for outaged blackstart units	X	X	X	X	X	X	X	X	X	X						16	**26**
Derated capacity of blackstart units	X	X	X		X	X	X	X	X	X						12	**21**
Status of transmission lines on alternative pathways	X	X	X	X	X		X	X	X	X						16	**25**

Status of remote/local control switches for blackstart units	X	X														14	**16**

Table 3.7-2 — Blackstart Information Monitored

Actions to be Taken

The survey inquired about what documented actions system operators are expected to take when blackstart capability is found to be inadequate, i.e., when a blackstart generator or key transmission path identified in the system restoration plan becomes unavailable or unusable. Table 3.7-3 summarizes the responses. Fewer respondents identify expected actions than report having documented practices for awareness of blackstart capability. The difference in number of respondents might indicate that some documented practices pertain more to long-term capability than to current conditions.

In addition to the expected operator actions listed in Table 3.7-3, one RC respondent comments that the RC's outage coordinators "make sure that multiple adjacent black-start units are not planned out at the same time." Others who responded to this section of the survey did not specifically state that the RC makes a concerted effort to avoid compromising system restoration plans when reviewing and approving planned outages. Table 3.7-3 shows that there is a range of expected responses to a loss of blackstart capability, rather than a consistent, uniform set of responses.

Documented Actions for Inadequate Blackstart Capabilities	RC1	RC2	RC3	RC4	RC5	RC6	RC7	RC8	RC9	RC10	RC11	RC12	RC13	RC14	RC15	Others	Total

Notify other entities (e.g., RCs, nuclear stations)	X	X	X		X	X										12	**17**

Table 3.7-3 — Documented Actions for Inadequate Blackstart Capability

Recommendations for New Reliability Standards

The *Outage Task Force Final Blackout Report* states that the NERC Reliability Standards are based on seven key concepts, one of which is emergency preparedness.[31] In the context of emergency preparedness, the report emphasizes the need for "procedures and capabilities to use 'black start' generators (capable of restarting with no external power source) and to coordinate operations in order to restore the system as quickly as possible to a normal and reliable condition."[32]

For the most part, the necessary "procedures and capabilities" are addressed in the EOP series of standards, in particular, NERC Reliability Standard EOP-005-0, System Restoration Plans. Although most of the requirements of this standard apply to long-term issues such as annual review and update of the plans, the standard contains a requirement (R8) that each TOP shall "ensure the availability and location of black-start capability within its area to meet the needs of the restoration plan." Although this requirement does not specify the time frame to which it applies, an argument can be made that it must apply to the near-term or real-time situational awareness of the availability and capability of blackstart facilities.

Although NERC Reliability Standard EOP-005-0, System Restoration Plans, requires each TOP to "ensure the availability and location of black-start capability within its area to meet the needs of the restoration plan," currently each TOP decides how to accomplish this goal.

Based on survey results, RTBPTF recommends that requirement R8 of NERC Standard-EOP-005-0 be revised to specify that operators receive the information they need to maintain situational awareness of the availability and capability of the blackstart generation and transmission resources identified in their system restoration plans. The task force also recommends that requirement R8 specify that operators be provided

[31] Outage Task Force Final Blackout Report, Pages 6–10.
[32] Ibid. Page 10.

documented practices and procedures that identify the information they should monitor to ensure adequate blackstart resources and the actions they should take if blackstart conditions are less than described in the restoration plan. The task force recommends that an operating guideline be developed to support the expanded requirement R8.

RTBPTF also recommends that NERC Standard-TOP-003-0, Planned Outage Coordination, be revised to include a requirement that scheduled outages of blackstart generation resources be coordinated so that key elements of the system restoration plan are not compromised without adequate alternative resources being available.

Recommendation – S35

Provide information to operators to maintain awareness of the availability and capability of the blackstart generators and transmission restoration paths.

RTBPTF Recommendation

RTBPTF recommends that requirement R8 of NERC Standard-EOP-005-0, System Restoration Plans, be revised to address operator awareness of the availability of blackstart resources, as follows:

PR1. Each transmission operator shall provide its operators with the information necessary to maintain awareness, in real time and on a current-day and day-ahead basis, of the availability and capability of the blackstart generation resources and transmission cranking paths identified in the system restoration plan. In addition, operators shall be provided documented practices and procedures that specify the information to be monitored to ascertain the availability and capability of blackstart resources and that identify the actions to be taken if blackstart availability or capability is less than that described in the restoration plan.

RTBPTF developed the following proposed measure (PM) for the proposed requirement above:

PM1. Each transmission operator shall demonstrate the documented practices and procedures that specify the information to be monitored to ascertain the availability and capability of blackstart resources and that identify the actions to be taken if blackstart availability or capability is less than that described in the restoration plan. In addition, each transmission operator shall demonstrate the user interface for visual presentation of the necessary information.

Recommendation – S36

Plan and coordinate scheduled outages of blackstart generators and transmission restoration paths.

RTBPTF also recommends that a requirement be added to Standard-TOP-003-0 to address scheduled outages of blackstart generation resources and/or key transmission restoration pathways.

PR2. Each reliability coordinator, transmission operator, balancing authority, and generator operator shall plan and coordinate scheduled outages of blackstart generation resources and/or key transmission restoration pathways so that the reliable capability of key elements of the system's restoration plans is not compromised without adequate redundant or alternative resources or plans being identified and available.

RTBPTF developed the following proposed measure for PR2:

PM2. Each reliability coordinator, transmission operator, balancing authority, and generator operator shall show evidence that the viability of the transmission owner's restoration plan is reaffirmed on a daily basis.

Rationale

The *Outage Task Force Final Blackout Report* reiterates the importance of having "procedures and capabilities" related to the blackstart resources needed to restore a transmission system following events such as the August 14, 2003, blackout. Reliability standards that address such procedures and capabilities currently focus on long-term issues such as verifying the capabilities of blackstart resources and updating blackstart procedures. The above recommendations will increase the scope and specificity of reliability standards to give operators the information and guidance they need to maintain situational awareness of the status, availability, and capability of blackstart resources and the viability of blackstart procedures in all time frames, up to and including real time. The findings of the Real-Time Tools Survey establish that documented procedures for maintaining situational awareness of blackstart capability are prevalent within the industry. The PRs and PMs presented above will establish formal, uniform requirements for documented and demonstrable procedures that will raise the bar for many reliability entities.

Recommendation – G12

Monitor and ensure operator awareness of current conditions of blackstart generators and status of transmission restoration paths.

Recommendations for Operating Guidelines

As discussed previously, every TOP is currently required to "ensure the availability and location of blackstart capability within its area to meet the needs of the restoration plan." Each TOP decides how to achieve this goal. Many survey respondents report that their system operators monitor a variety of information to maintain awareness of blackstart capability. Current practices provide a good guideline for others to follow in providing for the availability of blackstart resources.

RTBPTF recommends that an operating guideline be developed in support of requirement R8 of NERC Standard EOP-005-0, System Restoration Plans. The guideline should specify that system operators monitor the following information to maintain awareness of the current condition of blackstart resources:

- On-line/off-line status of blackstart generating units
- Scheduled return-to-service dates for outaged blackstart units
- Derated blackstart unit capacity
- Status of transmission lines along critical pathways for system restoration
- Scheduled return-to-service dates for outaged transmission lines along critical pathways for system restoration
- Status of transmission lines in alternative restoration pathways
- AVR status of blackstart units
- Fuel availability for blackstart units

The task force recommends that visualization techniques for efficiently and effectively providing system operators with information regarding blackstart capability, as listed in the operating guidelines recommended above, be developed by EMS vendors, EMS user groups, and the various forums available for the exchange of ideas among operators.

Areas Requiring More Analysis

RTBPTF identified no areas requiring additional analysis for blackstart capability.

Examples of Excellence

RTBPTF identified no examples of excellence related to blackstart capability.

Section 4.0
Power System Models

Introduction

An accurate real-time model is essential for assessing the reliability of the electric system. Real-time models that are too small, too large, too highly equivalenced, or inadequately maintained and updated can cause significant problems for entities that oversee reliability. A consistent, uniform set of modeling and data exchange practices, procedures, and standards will greatly facilitate the creation and subsequent maintenance of optimal models. The sections that follow summarize and analyze the model characteristics and modeling practices reported by respondents to the NERC Real-time Tools Survey. The analysis attempts to quantify some of the key characteristics of the respondents' network models and identifies modeling areas that need more analysis, from which recommendations for new reliability standards or guidelines may be forthcoming.

The fundamental responsibility of RCs, TOPs, and other entities that oversee grid reliability is to assure that the transmission system can be quickly restored to a secure state following any single contingency. The real-time tools that are necessary to assess the condition of the transmission system, such as the state estimator and contingency analysis, cannot function without a real-time model of the system. A real-time model is a high-fidelity representation of:

1) transmission and generation facilities within the area of responsibility of the reliability entity (the *internal network model*) and
2) facilities adjacent to and beyond the area of responsibility (the *external network model*) that can significantly impact voltage and flows within the area of responsibility or that provide a path for flows into or out of external facilities that can impact the area of responsibility.

Even the best-designed tools, no matter how advanced, can be severely compromised by inaccuracies and omissions in the network models on which they rely. Unfortunately, entities implementing network analysis applications for the first time often focus on the applications themselves and underestimate the cost, effort, and level of expertise required to build and maintain an adequate real-time network model.

Determining which facilities to represent in the internal network model is relatively straightforward. Typically, the internal model includes all bulk electric system facilities within the area of responsibility. Determining which facilities to represent in the external model is much more complex. There is no "bright line" that identifies external areas whose operations can impact the area of responsibility. Real-time modelers use a variety of criteria, analytical techniques, engineering judgment, and other methods to determine what to include and exclude in their external models. Although some variation in external models among regions is justified based upon the size and geographic location of a particular entity's area of responsibility, inconsistencies in identifying the relevant external facilities can lead to external models that are too small, too large, or too highly "equivalenced." In an equivalenced model, individual physical electrical elements are represented by a reduced set of non-physical elements that mimic the same electrical response as the individual elements. For example, multiple generating units may be represented by a single large generator that has the same total output, or a double-circuit line may be represented by a single-circuit line with the same effective impedance.

External models that are too small, too large, or too highly equivalenced each have characteristics that can negatively affect the quality of the results of the real-time network analysis tools that use them (and therefore the ability of reliability entities to do their jobs well).

External models that are too small may not include enough external transmission elements to accurately represent loop flows through external systems that can significantly impact internal facilities. In some cases, loop flows may not be represented at all or may be allocated in whole or in part to facilities in the external model over which they do not actually flow. A state estimator can often overcome this challenge in determining the actual flows and voltages on the internal facilities because it uses "best fit" algorithms (e.g., weighted least-squares methods) to estimate the current system state. However, contingency analysis cannot accurately calculate post-contingency flows on internal facilities if the branches that carry these flows are not accurately represented in nearby external facilities. The analysis may produce a solution that inaccurately suggests the system is secure when it is not, or the reverse. Similar problems can result when a model omits external facilities that would individually or collectively contribute to significant loading on internal facilities if those external facilities were out of service.

External models that are too large require more resources to maintain than they would otherwise. Reliability entities typically underestimate the resources required to build and maintain a real-time model and often do not have enough staff to keep up with both a detailed internal model and all the significant changes made to the external facilities included in a large, detailed external model. In addition, processes for notification of grid changes and exchange of relevant modeling data among reliability entities are minimal or even nonexistent in some regions. The result is that large, detailed models can gradually become inaccurate and obsolete over time. The state estimator may be able to overcome this challenge in determining the actual flows and voltages on internal facilities, but contingency analysis will not accurately calculate post-contingency flows and voltages on internal facilities if the representations of nearby external facilities are not correct. A large external model also causes network applications to use significant additional computer resources (memory, CPU cycles, discs, etc.), and these applications will take longer to solve. Consequently, the reliability entity may run state estimation, contingency analysis, and other network analysis applications less frequently.

External models that are highly equivalenced pose similar problems. A decision to represent a particular external facility as part of a fictitious "equivalent" element is usually based on a determination that the facility by itself does not have a significant impact on internal facilities but needs to be represented along with other similar facilities to provide a path for external flows into or out of facilities that are explicitly modeled. A problem occurs when a facility that has been incorporated into one or more equivalent elements has been upgraded in the field to the extent that it now needs to be modeled explicitly (e.g., from 115 kV to 230 kV). In most cases it is extremely difficult to deconstruct equivalenced elements into their constituent facilities for the purpose of remodeling one of them explicitly. The only sure way is to use equivalencing tools to recompute new external equivalent elements that are based on the new explicitly modeled facilities. This is a tedious, time-consuming task. For this reason, facility upgrades are often not incorporated into an equivalenced model. As above, the state estimator may be able to overcome this challenge in determining actual flows and voltages on the internal facilities, but contingency analysis will not be able to accurately reflect post-contingency flows on internal facilities if the representations of nearby external facilities are no longer correct.

Any external model that has not been sufficiently maintained can cause solution problems for the state estimator as well as contingency analysis and other applications that use the state estimator base case. The state estimator may have difficulty converging or fail to converge if the external model is outdated. In some cases, errors caused by poor external model fidelity can be "smeared" into internal facilities in the state estimator solution, causing inaccurate estimates for tie lines and other nearby internal facilities. Solution accuracy and convergence problems can impact contingency analysis similarly. When the state estimator fails to converge, real-time contingency analysis is effectively disabled. And even when the state estimator obtains a solution, a poor external model can cause contingency analysis to have convergence problems and/or yield erroneous solutions.

Good practice dictates that all relevant external electrical components, along with their associated real-time analog readings and circuit breaker and/or switch statuses, be modeled explicitly. Maintenance of accurate wide-area models requires continual exchange of system modeling data as well as exchange of real-time or near-real-time data with neighboring utilities. This exchange is required to support pertinent "instantaneous" metering and status information via SCADA/ICCP or other data links.

A consistent, uniform set of modeling and data-exchange practices, procedures, guidelines and/or standards facilitate the creation and subsequent maintenance of network models. RCs, TOPs, and all other entities responsible for reliability must have confidence that their neighbors are doing a competent job in assessing reliability and thereby protecting one another from harm. Real-time models are the foundation for these assessments. Therefore, all reliability entities have a vested interest in the quality and accuracy of their neighbors' real-time models.

RTBPTF recommends further analysis in the areas of model data exchange and grid change notification procedures, external model development guidelines, and the eventual use of CIM XML[1] for model exchange.

Significance to the August 14, 2003 Blackout

RTBPTF investigated the use of modeling data throughout the industry because the lack of real-time telemetry data in the external model was one of the contributing factors to the August 2003 blackout. MISO was using a static bus-branch network model in parts of its external model. When the Stewart-Atlanta 345-kV line tripped (monitored by the PJM RC), MISO's state estimator did not know that the line had gone out of service. This led to a data mismatch that prevented MISO's state estimator from computing a solution that could be used by its real-time contingency analysis application. Without real-time contingency analysis, MISO's ability to see that its system was in danger was greatly compromised.

Recommendations for New Reliability Standards

The Real-Time Tools Survey reveals that entities have significantly different practices for creating and maintaining models of the bulk electric system. Therefore, RTBPTF did not make any recommendations for the creation of new reliability standards pertaining to model practices. However, RTBPTF does identify several areas that require additional analysis to improve the state of modeling within the industry. The items that will require additional analysis include providing clarity to some fundamental definitions, identifying methods for grid change notification and model data exchange, developing external models, and implementing a CIM XML model exchange.

[1] The term "CIM XML" in this report refers to the language used for power system model exchange that conforms to the NERC common power system model (CPSM) specifications. "CIM" is the "Common Information Model" definition used to represent the power system. XML (extensible mark-up language") is an industry standard syntax used in the model data files.

Section 4.1
Model Characteristics

Definition

The majority of real-time applications used to monitor and study the health of the transmission grid require an electrical model of the interconnection, which is commonly referred to as the "network model." The network model has two components: the "internal model" and the "external model." The internal model represents the portion of the transmission grid for which the reliability entity is responsible (i.e., the electrical footprint of an RC or TOP). The external model represents the electric grid that surrounds an entity's primary area of responsibility.

Background

In general, the internal network model contains significantly more detail than the external model in terms of both voltage levels and the types of equipment represented. The external model also often contains "equivalent" elements. An equivalent element is a fictitious (non-physical) element that represents two or more physical elements (e.g., a single "generator" that represents multiple generators, a single "line" that represents multiple lines, etc.). Equivalent elements provide the same electrical response as the elements they replace in the model. They are generally employed on the outer edges and/or within lower-voltage levels of the model where physical representation is not critical.

Summary of Findings

The questions in the model characteristics section of the NERC Real-time Tools Survey were designed to capture essential characteristics of the respondents' internal and external network models. The information collected in this section of the survey also provides insight into the respondents' network modeling practices.

The data collected in this section of the survey are primarily related to the respondents' network model dimensions and modeling practices. This information is intended to provide context and support for information collected in other sections of the survey. The analysis of findings below is organized into the following modeling categories:

- general model size and detail
- future modeling plans
- applications that use the network model
- circuit breaker and switch modeling
- generator step-up transformer modeling

- generator auxiliary load modeling
- generating unit Mvar capability curve modeling
- verifying transmission-line characteristics
- transmission line real-time limits
- transformer real-time limits
- bus load modeling
- external network models

Some of the key survey findings are listed below:

- Survey respondents' network models vary widely in terms of size, as one would expect. However they also vary widely in modeling detail (in terms of switches and elementary bus nodes per station); internal-to-total bus ratios, internal-to-total branch ratios; analog and status measurement density; and other dimensions that are normalized by buses, stations, and other basic model dimensions. This wide variation was seen in responses from both RCs and non-RCs.

- A large number of respondents plan major changes in their network models that are "above and beyond routine model changes" in the coming year, particularly in their external models.

- An overwhelming majority of respondents consider the state estimator, real-time contingency analysis, study contingency analysis, and on-line power flow to be the most important applications that rely on the network model. Other network applications such as operator OPF, Volt-var dispatch, etc. were cited to a much lesser extent.

- Higher-voltage portions of respondents' power systems are modeled in more detail (in terms of power breakers and switches) than the lower-voltage portions of their systems. Also, circuit breaker devices are modeled more than switches (i.e., gangs, disconnects, etc.)

- An overwhelming majority of respondents model at least some generator step-up transformers, generator auxiliary loads, and generating unit Mvar capability curves in their internal network models. This is typically done for the larger generating units. Surprisingly, not all RCs model generating unit Mvar capability curves despite the importance of these curves for determining Mvar reserves.

- Half or fewer of survey respondents verify the electrical characteristics of their transmission lines.

- More than 75 percent of all survey respondents, including 90 percent of RCs, report that their network models support the use of real-time limits and/or multiple limit sets based on temperatures or seasons for lines and transformers. Of those respondents whose models support this feature, almost 90 percent are using it for lines, and about 75 percent are using it for transformers.

- The majority of respondents use multiple methods to determine the elements to include in their external models (e.g., off-line modeling utilities, system planning studies, etc.). Surprisingly, more than one-third of the RCs use "engineering judgment" as the sole means of determining what elements to include in their external models.

- CIM XML[2] is not currently used to a wide extent for model maintenance.

- Virtually all of the respondents have at least some real-time analog and/or status telemetry linked to their external network models. However the real-time analog/status point measurement density in the external models, in terms of measurements per station, varies widely. (Note: The lack of real-time telemetry data in the external model was one of the contributing factors in the August 2003 blackout).

The information in the subsections below is based upon an analysis of the data submitted by survey respondents. Note that because of the length of the survey and the volume of data involved, RTBPTF was not able to filter all of the responses for inconsistencies, omissions, and suspect data entries, or to follow up with each of the respondents.

General Model Size and Detail

The survey collected information on the size and detail of each respondent's network model. The data collected included basic network model dimensions such as numbers of buses, lines, breakers, switches, transformers, and other system elements. Network model size is commonly expressed in terms of buses and branches.[3] Table 4.1-1 and Table 4.1-2 show the numbers of model buses and branches reported by survey respondents.[4]

From Table 4.1-1 we see that the network models used by RCs vary widely in size from 687 buses to more than 30,000 buses. From Table 4.1-2 we see that the models used by all other respondents (e.g., TOPs and BAs) also vary widely

---

[2] The term "CIM XML" in this report refers to the language used for power system model exchange that conforms to the NERC common power system model (CPSM) specifications. "CIM" is the "Common Information Model" definition used to represent the power system. XML (extensible mark-up language") is an industry standard syntax used in the model data files.
[3] A "branch" in this context includes lines (real or equivalent), transformers (of any type), "zero impedance" branches, and series capacitors/reactors.
[4] The identities of the respondents in this and other sections of this report have been masked. The identifiers used for each respondent change in each table and figure. That is, respondent "RC01" in one figure or table is not necessarily the same respondent as "RC01" in a different figure or table.

in size from 14 buses to more than 24,000 buses. The charts in Figure 4.1-1 and Figure 4.1-2 graphically illustrate this. Both RCs and the other respondents exhibit similar wide variations in the number of model branches.

The size of each survey respondent's external model relative to the total model size also varies widely. This variation is clearly illustrated by the differences in the respondents' external bus to total bus ratios, as can be seen in Table 4.1-1 and Table 4.1-2 (see also Figure 4.1-3 and Figure 4.1-4). A similar variation is also seen in the external-branch-to-total-branch ratios. RCs report external-bus-to-total-bus model ratios that ranged from less than one percent to almost 81 percent while all other respondents report ratios that varied between seven and 67 percent. Similarly, RCs report external-branch-to-total-branch ratios that range from less than one percent to 82 percent. The other respondents had external-branch-to-total-branch ratios that range from less than one percent to 94 percent.

Some of the wide variation in external model sizes can be explained by a respondent's geographic location within an interconnection. For instance, a system in Florida with interconnection ties only to the north would likely require a smaller external model than a system in Ohio with ties to the interconnection on all sides. However, much of this variation is also due to the diversity of modeling approaches and philosophies used to determine how large an external model is required to support network applications. This topic is addressed in greater detail in Section 4.2, Modeling Practices and Tools, of this report.

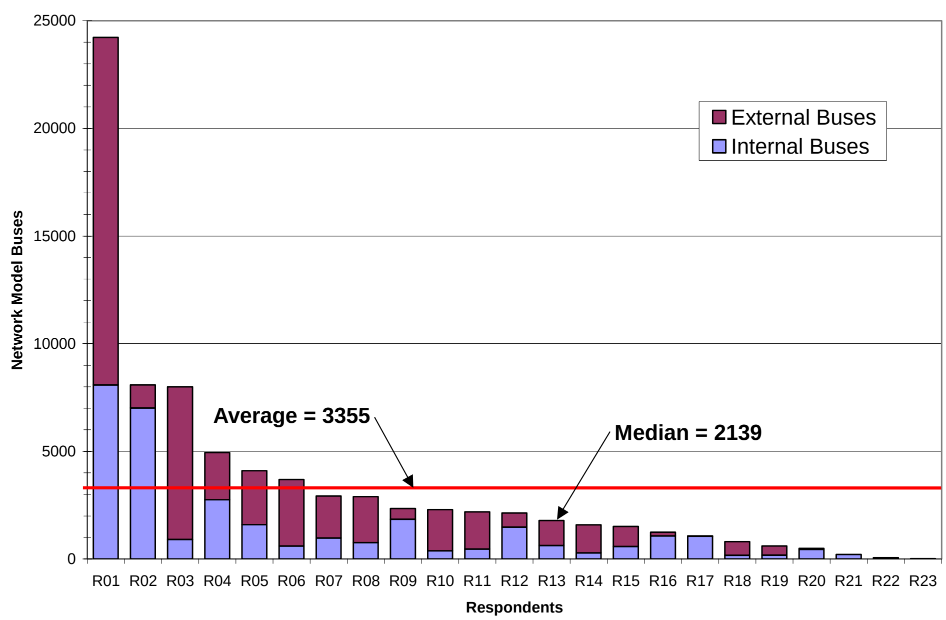

Figure 4.1-2

External Bus to Total Bus Ratios for RCs

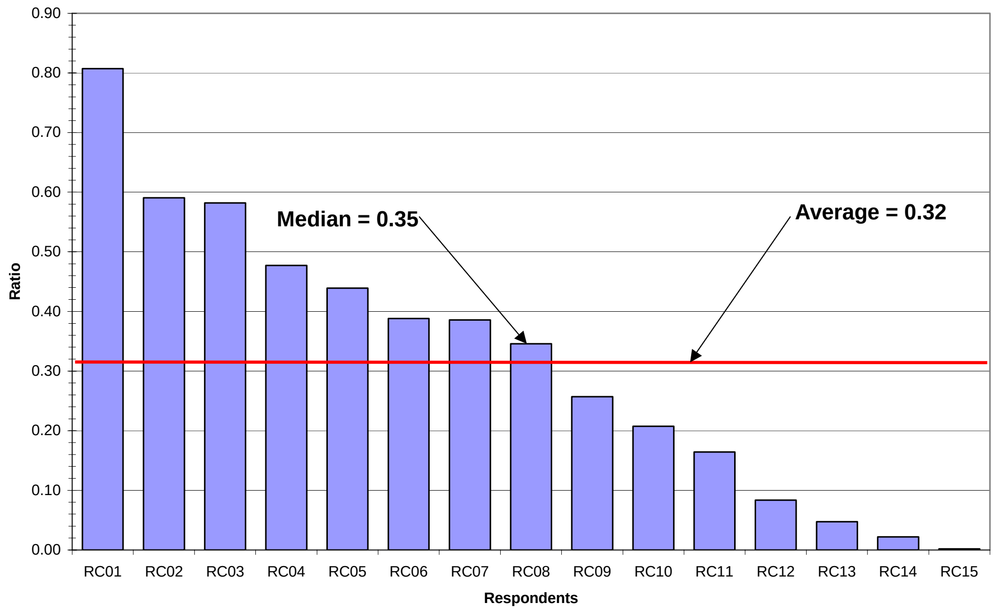

Figure 4.1-3

External Bus to Total Bus Ratios for Other (Non-RCs) Respondents

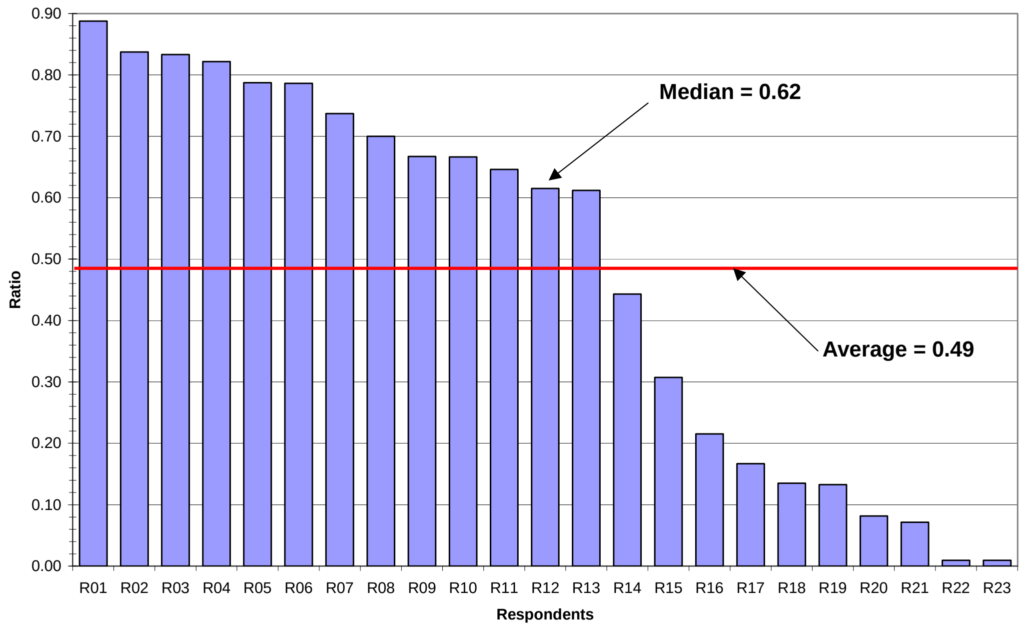

Figure 4.1-4

Approximate measures for quantifying model detail were computed to compare the level of detail in respondents' models. The two measures that were used were:

- Breakers and switches per station ratio
- Elementary bus nodes per electrical bus ratio

These are very rough measures that are affected by many transmission system specific characteristics. However they provide a good approximation of modeling detail in most cases. In general, a more detailed model (in terms of equipment and voltage levels modeled) will contain larger numbers of breakers and switches per station than one with less detail. The same is true for the node-to-bus ratio because modeling additional equipment generally requires that the model use more nodes. In the extreme case of a planning model (i.e., a bus-branch model), the breakers and switches per station ratio for is zero. The node-to-bus ratio for a planning model is one.

Table 4.1-3 and Table 4.1-4 show the number of stations, breaker-and-switch totals, and the breakers-and-switches-to-station ratios for the RCs and other respondents. Table 4.1-5 and Table 4.1-6 show the number of buses, elementary bus nodes, and the elementary-bus-nodes-per-bus ratios for the RCs and other respondents. In each of these tables, the raw data and computed ratios are shown for the internal model, the external model, and total model.

From Table 4.1-3 and Table 4.1-4, we see that the breakers-and-switches-per-station ratios vary widely among respondents. This is true for both the RCs and other respondents. We also see that the computed ratio is larger for the internal model than it is for the external model for most respondents. In many of the cases where the external ratio is large, it seems to be because the external model is very small relative to the total model. The average and median ratios for the internal models are significantly larger than those for the external models, as one might expect.

From Table 4.1-5 and Table 4.1-6, we see that the elementary-bus-node-to-electrical-bus-node ratios also vary widely among respondents. The computed values of the node-to-bus ratios vary the same way that the breakers-and switches-per-station ratio varies. That is, there is wide variation for both the RCs and other respondents. Also, the ratio for the internal model is larger than it is for the external model in most cases. As with the breaker-and-switch-per-station ratios, the average and median node-to-bus ratios for the internal models are significantly larger than those for the external models.

One can conclude these ratios are generally larger for the internal models because they contain more breaker/switch detail than the external models. This is consistent with what one would expect. The large variation among respondents in the ratios can be explained, in part, by a number of factors related to the physical characteristics of the systems being modeled (e.g., the bus and breaker schemes used on the bulk electric system, etc.). However, another likely reason for this variation is differences in the respondents' modeling philosophies and practices. This will be illustrated later by some of the other survey responses that will be discussed.

Table 4.1-6 — Elementary Node-to-Bus Ratios for Other (non-RC) Respondents

Future Modeling Plans

The models used by network applications require continual maintenance to reflect changes that occur in the interconnection that are both internal and external to an entity's reliability footprint. Survey respondents were asked to identify the "major" modeling activities that they were planning in the upcoming year that were "above and beyond of what is considered routine maintenance." Approximately 88 percent (15 of 17) of the RCs and 75 percent (18 out of 24) of other respondents plan make major changes to their network models within the coming year. Table 4.1-7 summarizes these responses.

Major Model Changes in Coming Year	RC01	RC02	RC03	RC04	RC05	RC06	RC07	RC08	RC09	RC10	RC11	RC12	RC13	RC14	RC15	RC16	RC17	Others	**Total**
Adding breaker/switch detail to external model	X	X	X	X			X	X	X							NR	NR	7	**14**
Adding breaker/switch detail to internal model	X	X	X	X	X											NR	NR	7	**12**
Adding extensive telemetry to external model	X	X	X			X	X	X	X							NR	NR	6	**13**
Adding extensive telemetry to internal model	X	X		X	X	X							X			NR	NR	3	**9**
Adding lower-voltage detail to external model	X									X						NR	NR	3	**5**
Adding lower-voltage level detail to internal model	X	X	X	X												NR	NR	4	**8**
Adding one or more control areas to external model	X					X										NR	NR	3	**5**
Creating a new external model	X									X	X	X			X	NR	NR	10	**15**
Others			X		X						X			X		NR	NR	5	**9**

Table 4.1-7 — Major Model Changes Planned in the Upcoming Year

The most common changes planned by the 15 RC respondents are "adding breaker/switch detail to the external model" (47 percent, 7 out of 15), and "adding extensive telemetry to the external model" (47 percent, 7 out of 15). These are closely followed by "adding extensive telemetry to the internal model" (40 percent, 6 out of 15), "adding breaker/switch detail to the internal model" (33 percent, 5 out of 15), and "creating a new external model" (33 percent, 5 out of 15). Therefore, from the table we can see that 75 percent (12 out of 15) of RC respondents are making one or more major changes to their external models in the coming year.

The most common model changes planned by the other non-reliability coordinator respondents are "creating a new external model" (56 percent, 10 out of 18), "adding breaker/switch detail to the external model" (39 percent, 7 out of 18), "adding extensive telemetry to the external model" (33 percent, 6 out of 18), and "adding breaker/switch detail to the internal model" (39 percent, 7 out of 18).

The observations above suggest that most major network model changes that the survey respondents will be implementing in the near term are related to external network model improvements. These types of changes enhance the wide-area analysis capabilities provided by the various EMS network analysis applications that were recommended by Macedo (2004).[8]

[8] Macedo, Frank. Consultant to FERC. 2004. *Reliability Software Minimum Requirements & Best Practices*. FERC Technical Conference, July 14. http://www.ferc.gov/EventCalendar/Files/20040716092511-20040714085315-FrankMacedo.pps

Applications that use the Network Model

A total of 41 entities, including 100 percent (17 out of 17) of the RCs, responded to the survey question that identified the applications that use their network models. Table 4.1-8 lists the on-line and off-line applications that use the survey respondents' network models.

Applications that Use the Network Model	RC01	RC02	RC03	RC04	RC05	RC06	RC07	RC08	RC09	RC10	RC11	RC12	RC13	RC14	RC15	RC16	RC17	Others	Total
State estimator	X	X	X	X	X	X	X	X	X	X	X	X	X	X	X	X	X	19	**36**

Volt/Var dispatch (OPF)	X			X			X											5	**8**
Available Transfer Capability and Total Transfer Capability (ATC/TTC) applications	X	X				X		X			X							2	**7**
Market systems	X	X			X	X		X	X	X									**7**
Fault locator			X															2	**3**

Table 4.1-8 — Applications that Use the Network Model

From Table 4.1-8 we see that 100 percent (17 out of 17) of the RCs and 79 percent (19 out of 24) of the other respondents reported that their network models are used by their state estimator, real-time contingency analysis, and study contingency analysis applications. Ninety-four percent (16 of 17) of RCs and 79 percent (19 out of 24) of the other respondents report that their network models are used by their on-line power flow application. One can conclude that these four applications are clearly the ones that all of the survey respondents, regardless of their role, perceive as most important to their operations.

The respondents use their network models in other applications to a lesser extent. From Table 4.1-8 we see that 41 percent (7 out of 17) of the RCs and 25 percent (6 of 24) of the other respondents use their network models in an OPF application. Forty-one percent (7 out of 17) of RCs and 13 percent (3 out of 24) of other respondents use their network models in equipment-outage scheduling applications. Eighteen percent (3 out of 17) of RCs and 21 percent (5 out of 24) of other respondents use their models in Volt/Var dispatch applications (which are generally OPF applications). Twenty-nine percent (5 out of 17) of RCs and 8 percent of the other respondents use their network models in available transfer capability (ATC)/total transfer capability (TTC) applications. Forty-one percent (7 out of 17) of RC respondents and none of the other respondents use their network models in market-related applications. The network models are used by other applications to a lesser extent because:

- Some of the applications listed are only needed by entities that have markets or other special needs.

- Applications such as OPF are much more difficult to implement and maintain than the state estimator, contingency analysis, and on-line power flow. Consequently, they are generally not implemented unless there is a pressing need for them that justifies the cost.

Breaker/Switch Modeling

The survey reveals that, in their internal models, respondents represent a higher percentage of their existing circuit breakers at high-voltage levels than at lower-voltage levels. This is what one would intuitively expect. Table 4.1-9 and Table 4.1-10 summarize the actual survey responses for all RC respondents and non-RC respondents, respectively, regarding this issue.[9]

Voltage Range	N/A	<5 percent	5-25 percent	26-50 percent	51-75 percent	76-95 percent	>95 percent	**Total**
Voltage: 345 - 765 kV	1		1			1	12	**15**
Voltage: 100 - 230 kV	1				2	4	8	**15**
Voltage: < 100 kV	3		3	1		4	4	**15**

Table 4.1-9 — Percentage of Internal System Breakers Modeled for RCs

Voltage Range	N/A	<5 percent	5-25 percent	26-50 percent	51-75 percent	76-95 percent	>95 percent	**Total**
Voltage: 345 - 765 kV	6	2	2				14	**24**
Voltage: 100 - 230 kV	4		1	1	2	4	14	**26**
Voltage: < 100 kV	5		2	3	4	2	9	**25**

Table 4.1-10 — Percentage of Internal System Breakers Modeled for Other (non-RC) Respondents

The survey results also indicate that the higher-voltage portions of the internal system models contain more detail regarding circuit breakers than do the lower-voltage portions. For example, more than 85 percent (12 out of 14, excluding "N/A" responses) of survey respondents state that more than 95 percent of their circuit breakers were modeled for the portions of their internal system models for 345 kV and higher; less than 40 percent (4 out of 14, excluding "N/A" responses) state that 95 percent of their breakers were modeled below the 100-kV level.

Table 4.1-11 and Table 4.1-12 summarize the survey results for modeling internal system switches (i.e., disconnects, gangs, etc.) for RC and other respondents respectively.

[9] The number of respondents varied depending on voltage range. This is probably because some respondents did not select "N/A" for voltage ranges they do not have in their systems.

Voltage Range	N/A	<5 percent	5-25 percent	26-50 percent	51-75 percent	76-95 percent	>95 percent	Total
Voltage: 345 - 765 kV	1		1	2	1	2	8	**15**
Voltage: 100 - 230 kV	1		1	3	2	2	6	**15**
Voltage: < 100 kV	3	1	2	2	1	4	2	**15**

Table 4.1-11 — Percentage of Internal System Switches Modeled for RC Respondents

Voltage Range	N/A	<5 percent	5-25 percent	26-50 percent	51-75 percent	76-95 percent	>95 percent	Total
Voltage: 345 - 765 kV	6	2	-	1	1	1	11	**22**
Voltage: 100 - 230 kV	4		2	3	1	3	11	**24**
Voltage: < 100 kV	5	1	3	1	6	1	7	**24**

Table 4.1-12 — Percentage of Internal System Switches Modeled for Other (non-RC) Respondents

The responses regarding the modeling of switches in the internal system are similar to those regarding the modeling of circuit breakers, as indicated in Table 4.1-11 and Table 4.1-12. The majority of respondents model higher-voltage switches for greater than 95 percent of their systems; lower-voltage switches are generally modeled for less of their systems. By comparing the response summaries in Table 4.1-9 and Table 4.1-10 to those in Table 4.1-11 and Table 4.1-12, we can see that breakers are modeled more often than switches for each voltage range for both RC and other respondents. This is most likely because some entities that include breakers in their models choose not to include disconnect detail in their power system models as a matter of practice.

From these observations, we may conclude that:

1) Survey respondents model breakers and switches in more detail at higher voltages than at lower voltages.
2) Survey respondents model a smaller percentage of their switches than their breakers.

Generator Step-Up Transformer Modeling

Eighty-eight percent (38 out of 43) of survey respondents include at least some of their internal system generator step-up (GSU) transformers in their internal network models. This includes 100 percent (17 out of 17) of RC respondents and 81 percent (21 out of 26) of the other respondents. Table 4.1-13 summarizes the criteria used by the RC and other respondents to determine whether or not a GSU is modeled in their internal network model.

GSU Modeling Criteria for Internal Model	RC01	RC02	RC03	RC04	RC05	RC06	RC07	RC08	RC09	RC10	RC11	RC12	RC13	RC14	RC15	RC16	RC17	Other	**Total**
Based on available telemetry data (SCADA, ISN, etc.)	X	X	X	X	X	X	X	X		X	X	X	X					10	**22**
Based on unit size (MVA)	X	X	X	X	X	X	X	X	X									11	**20**
Other(s)	X	X	X	X					X					X	X	X	X	3	**12**
Based on unit type (coal, nuke, hydro, etc.)	X																	3	**4**
Based on the size of the auxiliary load																		1	**1**

Table 4.1-13 — Modeling Criteria for Internal System Generator Step-Up Transformers

From Table 4.1-13 we see that the most common criterion used to determine whether or not to model a GSU for an internal system generator is the "availability of telemetry data," which was selected by 58 percent (22 out of 38) of the respondents that model internal GSUs. This includes 71 percent (12 out of 17) of the RC respondents and 47 percent (10 out of 21) of the other respondents. This was closely followed by "based on the unit size (MVA)" which was selected by 52 percent (20 out of 38) of the respondents that model internal GSUs. This includes 53 percent (9 out of 17) of the RC respondents and 52 percent (11 out of 21) of the other respondents.

Forty-four percent (19 out of 43) of the survey respondents model GSUs for at least some external generating units in their external system models. This includes 59 percent (10 out of 17) of the RC respondents and 38 percent (10 out of 26) of the other respondents. Table 4.1-14 summarizes the criteria that RC and other respondents use to determine whether or not a GSU for an external generating unit will be included in their external network model.

External GSU Modeling Criteria	RC01	RC02	RC03	RC04	RC05	RC06	RC07	RC08	RC09	RC10	RC11	RC12	RC13	RC14	RC15	RC16	RC17	Other	**Total**
Based on available telemetry data	X	X	X	X	X	X					NR	NR	NR	NR	NR	NR	NR	6	**12**
Based on unit size (MVA)	X	X	X	X			X				NR	NR	NR	NR	NR	NR	NR	3	**8**
Other(s)	X							X	X	X	NR	NR	NR	NR	NR	NR	NR	2	**6**

Table 4.1-14 — Criteria Used for Modeling External Network GSUs

From Table 4.1-14 we see that the most common criterion used to determine whether or not to model a GSU for an external system generator is the "availability of telemetry data," which was selected by 63 percent (12 out of 19) of the respondents that model external GSUs. This includes 60 percent (6 out of 10) of the RC respondents and 67 percent (6 out of 9) of the other respondents. This was followed by "based on the unit size (MVA)," which was selected by 42 percent (8 out of 19) of the respondents that model internal GSUs. This includes

50 percent (5 out of 10) of the RC respondents and 33 percent (3 out of 9) of the other respondents that model external GSUs.

It is worth noting that survey respondents favor the same criteria for determining whether or not to model GSUs for both internal and external units. However, both RC respondents and the other respondents model external GSUs to a lesser extent. This is probably because 1) the required modeling information for the external units and their GSUs is more difficult to acquire, and 2) the level of detail required in external models is generally less than that required in internal models.

Generator Auxiliary Load Modeling

Seventy-one percent (29 out of 41) of the respondents model at least some of their internal generating unit auxiliary loads in their internal network models. This includes 71 percent (12 out of 17) of the RC respondents and 71 percent (17 out of 24) of the other respondents. Table 4.1-15 summarizes the criteria used by the RC and other respondents to determine which internal generating unit auxiliary loads to model.

Criteria Used to Determine Which Generating Unit Auxiliary Loads to Model	RC01	RC02	RC03	RC04	RC05	RC06	RC07	RC08	RC09	RC10	RC11	RC12	RC13	RC14	RC15	RC16	RC17	Others	**Total**
Based on available telemetry data	X	X	X	X		X							NR	NR	NR	NR	NR	10	**15**
Based on unit size (MVA)	X	X	X	X	X				X	X			NR	NR	NR	NR	NR	3	**10**
Based on available MW/Mvar measurements	X	X	X	X	X	X	X						NR	NR	NR	NR	NR	3	**10**
Based on the size of the auxiliary load	X	X				X	X	X					NR	NR	NR	NR	NR	3	**8**
Other(s)	X		X		X						X	X	NR	NR	NR	NR	NR	3	**8**
Based on unit type (coal, nuke, etc.)		X		X				X					NR	NR	NR	NR	NR	1	**4**

Table 4.1-15 — Criteria for Internal Generator Auxiliary Load Modeling

From Table 4.1-15 we see that the most common criterion used to determine whether or not to model generator auxiliary loads for internal system generators is “available telemetry data.” This criterion was selected by 52 percent (15 out of 29) of the respondents that model internal generator auxiliary loads. This includes 42 percent (5 out of 12) of the RC respondents and 59 percent (10 out of 17) of the other respondents. The second and third most common criteria used by the respondents were “unit size” and “available MW/Mvar” measurements. Both of these criteria were selected by 34 percent (10 out of 29) of the respondents which included 58 percent (7 out of 12) of the RC respondents and 18 percent (3 out of 17) of the other respondents.

Only 15 percent (6 out of 41) of the respondents model external generator auxiliary loads in their external network models. This includes 24 percent (4 out of 17) RC respondents and 8 percent (2 out of 24) of the other respondents.

Unit Mvar Capability Curves

Sixty-eight percent (30 out of 44) of the survey respondents reported that they model internal generating unit Mvar capability curves in their internal models. This includes 82 percent (14 out of 17) of the RC respondents and 59 percent (16 out of 27) of the other respondents. It is surprising that 3 of the 17 RCs do not include generating unit capability curves in view of the importance of these curves in determining Mvar reserves and improving voltage calculations by applications such as contingency analysis.[10]

Table 4.1-16 summarizes the methodologies used by respondents that model internal network model generator Mvar capability curves.

[10] RTBPTF did not contact the RCs who were not modeling generating unit Mvar capability curves to determine why they do not model them.

Internal Generating Unit Mvar Capability Curve Development	**RC01**	**RC02**	**RC03**	**RC04**	**RC05**	**RC06**	**RC07**	**RC08**	**RC09**	**RC10**	**RC11**	**RC12**	**RC13**	**RC14**	**RC15**	**RC16**	**RC17**	**Other**	**Total**
Based on original design curves	X	X		X	X									X	NR	NR	NR	13	**18**
Provided by the unit owners	X	X		X	X	X		X	X	X	X	X			NR	NR	NR	3	**13**
Other(s)	X	X	X				X								NR	NR	NR	1	**5**
Approximated based on unit type, size, etc.	X		X										X		NR	NR	NR	2	**5**

Table 4.1-16 — Methodologies Used to Develop Internal Unit Mvar Capability Curve Models

From Table 4.1-16 we see that the most common criterion used to develop internal generator Mvar capability curves was “based on original design curves.” Sixty percent (18 out of 30) of the survey respondents selected this response. This includes 36 percent (5 out of 14) of the RC respondents and 81 percent (13 out of 16) of the other respondents that model internal generator Mvar capability curves. It is not surprising that most of the respondents that chose this answer are the “other” (non-RC) respondents because they would be more likely to be unit owners.

Forty-three percent (13 out of 30) of the respondents base their internal generator Mvar capability models on data provided by the generating unit owners. This includes 71 percent (10 out of 14) of the RC respondents and 19 percent (3 out of 16) of the other respondents that model internal capability curves. It is not surprising that most of the respondents that chose this response were RCs because in many cases they do not own generation and would need to rely on information provided by the asset owners.

Table 4.1-18 summarizes the responses to the question “how do you verify the accuracy of the Mvar capability curves?” There were 30 respondents to this question, which included 14 RC respondents and 16 other respondents.

Verifying the Accuracy of Unit Mvar Capability Curves	RC01	RC02	RC03	RC04	RC05	RC06	RC07	RC08	RC09	RC10	RC11	RC12	RC13	RC14	RC15	RC16	RC17	Others	**Total**

Other(s)				X	X	X									NR	NR	NR	2	**5**

Table 4.1-17 — Methodologies Used to Verify Internal Model Mvar Capability Curves

Table 4.1-17 summarizes the survey responses regarding how the respondents that model their internal generator Mvar capability curves verify the accuracy of these curves. Fifty percent (15 out of 30) of the respondents that model them do not verify their accuracy at all. This includes 43 percent (6 out of 14) of the RC respondents and 56 percent (9 out of 16) of other respondents. Of those 15 respondents that do verify their Mvar capability curve accuracy, 87 percent (13 out of 15) of the respondents perform periodic tests at generating plants. The remainder of those who test use “other” means.

Table 4.1-18 summarizes the methodologies used by respondents that model external network model generator Mvar capability curves.

Fifty-one 50 percent (22 out of 43) of the survey respondents report that they model generator Mvar capability curves in their external models. This includes 71 percent (12 out of 17) of the RC respondents and 38 percent (10 out of 26) of the other respondents. Table 4.1-18 summarizes how the respondents develop their external model generating unit Mvar capability curves.

External Generating Unit Mvar Capability Curve Development	RC01	RC02	RC03	RC04	RC05	RC06	RC07	RC08	RC09	RC10	RC11	RC12	RC13	RC14	RC15	RC16	RC17	Other	**Total**
Approximated based on units of similar type, size, etc.	X	X	X	X	X	X	X	X					NR	NR	NR	NR	NR	8	**16**
Provided by the unit owners	X								X	X	X		NR	NR	NR	NR	NR	2	**6**
Other(s)									X			X	NR	NR	NR	NR	NR	1	**3**

Table 4.1-18 — Methodologies Used to Develop External Model Mvar Capability Curves

Seventy percent (16 out of 22) of the respondents that model external unit capability curves report that they model external generating unit Mvar capability curves using “approximations based on the generator unit characteristics such as MVA size, type, etc.” This includes 67 percent (8 out of 12) of the RC respondents and 80 percent (8 out of 10) of the other respondents. This is likely because the curve data are more difficult to obtain from the external entities that own the units. In addition, modeling accuracy is not considered a significant issue in most cases because generating units in the external model are usually electrically distant from the internal system. Consequently, inaccuracies in the Mvar capability curves will not usually have a significant impact on the voltages computed by the network applications in the internal portion of the model.

Verifying Transmission Line Characteristics

There were 43 respondents to the survey questions related to the verification of transmission-line characteristics. The respondents included 16 RCs and 27 other respondents.

Table 4.1-19 summarizes the responses and the breakdown of the respondents. Only 46 percent (20 out of 43) of the respondents verify the electrical characteristics of their transmission lines. This includes 50 percent (8 out of 16) of the RC respondents and 44 percent (12 out of 27) of other respondents.

Do you Verify T-Line Characteristics?	RC	Other	**Total**
No	8	15	**23**
Yes	8	12	**20**
Totals	16	27	**43**

Table 4.1-19 — Verification of Transmission-Line Limits

Table 4.1-20 shows the methodology used by each of the 20 respondents that verify transmission line characteristics. The most common method that is used by 65 percent (13 out of 20) of the respondents that verify transmission line characteristics was “based on voltage and flow readings at each end of the line.” This includes 38 percent (3 out of 8) of the RC respondents and 83 percent (10 out of 12) of the other respondents that verify transmission-line characteristics. The second most common method used by 30 percent (6 out of 20) of the respondents was “based on field data and planning models.” These respondents included 3 RCs and 3 other respondents. Surprisingly, only one respondent uses state estimator results. However, respondents may have interpreted “based on voltage and flow readings at each end of the line” as using state estimator readings. Note that only two respondents use actual field tests with special field equipment.

Methods used to Verify T-Line Characteristics	RC01	RC02	RC03	RC04	RC05	RC06	RC07	RC08	RC09	RC10	RC11	RC12	RC13	RC14	RC15	RC16	RC17	Others	**Total**

Table 4.1-20 — Methods used to Verify Transmission-Line Characteristics

Transmission Line Real-Time Limits

Nearly 80 percent (33 out of 42) of the respondents reported that their EMS network models support use of “real-time” limits and/or multiple limit sets based on temperatures or seasons for transmission lines. These 33 respondents included 16 RCs and 17 other respondents. Of the 33 respondents that have this capability, 88 percent (29 out of 33) of all respondents make use of these features. This includes 88 percent (14 out of 16) of the RC respondents and 88 percent (15 out of 17) of the other respondents that have this capability. Table 4.1-21 shows how each of the respondents implements real-time limits and/or multiple limit sets for transmission lines.

Methods Used to Implement Real Time Limits	RC01	RC02	RC03	RC04	RC05	RC06	RC07	RC08	RC09	RC10	RC11	RC12	RC13	RC14	RC15	RC16	RC17	Others	**Total**
Discrete limit sets manually selected by operators	X	X	X	X								X	X	X	NR	NR	NR	10	**17**
Dynamically computed from weather variables	X	X	X			X	X			X					NR	NR	NR	3	**9**
Discrete limit sets automatically selected	X	X			X	X	X								NR	NR	NR	1	**6**
Telemetered limits from real-time line rating devices	X		X	X					X						NR	NR	NR		**4**
Others		X			X			X			X				NR	NR	NR	1	**5**

Table 4.1-21 — Methods used to Implement Real-Time Limits

Fifty-eight percent (17 out of 29) of all the respondents that have implemented real-time limits and/or multiple limit sets say that they use “discrete limit sets that are manually selected by the operators” for at least some of their transmission lines. This includes 50 percent (7 out of 14) of the RC respondents and 67 percent (10 out of 15) of the other respondents. Thirty-one percent (9 out of 29) of the respondents use limits that are “dynamically computed from weather variables.” This includes 42 percent (6 out of 14) of the RC respondents and 20 percent (5 of 15) of the other respondents. The acquisition of telemetered limits from real-time rating devices was only used by 14 percent (4 out of 29) of the respondents, which included 29 percent (4 of 14) of the RC respondents and none of the other respondents.

Table 4.1-22 shows the number of limit sets used by the 26 respondents that report that they use of multiple limit sets.

No. Of Limit Sets Used for Lines	RCs	Others	All
2	5	5	10
3	3	3	6
4	2	2	4
7		1	1
8		1	1
16	2		2
20	1		1
24		1	1
Total	**13**	**13**	**26**[11]

Table 4.1-22 — Number of Limit Sets Used for Transmission Lines

[11] These figures do not add up to 29. Apparently some of the respondents (1 RC and 3 other respondents) that said they use multiple limit sets but failed to answer the follow-up questions related to the number of sets used.

The number of limit sets used by the survey respondents varies widely from 2 to 24. It is interesting to note that 38 percent (10 out of 26) of the respondents use only 2 limits sets. This includes 35 percent (5 out of 13) of the RC respondents and 38 percent (5 out of 13) of the other respondents. Seventy-seven percent (20 out of 26) of all respondents and 77 percent (10 out of 13) of the RC respondents use 4 or fewer limit sets.

Transformer Real-Time Limits

Seventy-six percent (32 out of 42) of survey respondents have network models that support the use of real-time limits and/or multiple limit sets based on temperatures or seasons for transformers. This includes 94 percent (16 out of 17) of the RC respondents and 65 percent (17 out of 26) of the other respondents. Of the 33 respondents that have this capability, 76 percent (25 of out 33) are making use of these features. This includes 75 percent (12 out of 16) of the RC respondents and 82 percent (14 out of 17) of the other respondents.

Table 4.1-23 shows the number of limit sets used for transformers by each of the 25 respondents that employ them. As with transmission lines, the number of limit sets used by the respondents for transformers varies widely from 2 to 24 limit sets.

Number of Limit Sets Used for Transformers	RC	Other	All
2	4	6	10
3	5	2	7
4	1	1	2
7	1	1	2
8		1	1
16	2		2
24		1	1
Total	**13**	**12**[12]	**25**

Table 4.1-23 — Number of Transformer Model Limit Sets

Forty percent (10 out of 25) of the respondents, which include 31 percent (4 out of 13) of the RC respondents, use only 2 limit sets. Seventy-six percent (19 out of 25) of the respondents, including 77 percent (10 out of 13) of the RC respondents and 75 percent (9 out of 12) of the other respondents that use multiple limit sets use 4 or fewer sets.

[12] One of the "Other" respondents that uses multiple limit sets did not provide information on how many they use.

Bus Load Modeling

Forty respondents, which include 17 RC respondents and 23 other respondents, answered questions related to the busload modeling capabilities of their EMS network models. Table 4.1-24 summarizes their responses.

EMS Network Model Bus Load Modeling Features and Usage	RCs		Others	
	Supported	Used	Supported	Used
Mapping of real-time load measurements to load models	15	15	17	14
Non-conforming Loads	12	11	14	10
Hourly Loads by day of week and hour	12	9	14	12
Models adapt based on state estimator solution	13	10	9	6
Holiday/Abnormal Day load modeling	11	2	10	2
Hourly Mvar or power factor by day of week and hour	7	5	12	7
Input from the System Load Forecast application	9	6	6	3
MW/Mvar Bus loads vary as function of bus voltage	8	2	6	1
Individual load profile from an external application for an area, bus, feeder, etc.	5	3	4	3

Table 4.1-24 — Load Model Features Supported/Used

Eighty percent (32 out of 40) of the respondents, including 88 percent (15 out of 17) of the RC respondents and 74 percent (17 out of 23) of the other respondents, have the capability to map real-time measurements to the load modeled in their network models. Of those that have this capability, 91 percent (29 out of 32) of the respondents, including 100 percent (15 out of 15) of the RC respondents and 74 percent (14 out of 23) of other respondents, utilize this feature.

Fifty-five percent (22 out of 40) of the respondents, which includes 76 percent (13 out of 17) of the RC respondents and 39 percent (9 out of 23) of the other respondents, have EMS load models that adapt over time based on the state estimator solution. Of the respondents that have this feature, 72 percent (16 out of 22) of the respondents, which include 77 percent (10 out of 13) of the RC respondents and 67 percent (6 out of 9) of the other respondents, make use of it.

Only 35 percent (14 out of 40) of respondents' network models, including 47 percent (8 out of 17) of the RC respondents and 26 percent (6 out of 23) of the other respondents, support voltage-sensitive loads. Of the 14 respondents whose models support this feature, only 21 percent (3 out of 14) actually make use of it.

Table 4.1-25 and Table 4.1-26 below show the frequency of internal and external bus load model updates. Sixty-eight percent (28 out of 41) of the respondents, which includes 65 percent (11 out of 17) of the RC respondents and 71 percent (17 out of 24) of the other respondents, report that the frequency of updates for their internal bus load models is "other." Seventy percent (29 out of 41) of the respondents, which includes 65 percent (11 out of 17) of the RC respondents and 75 percent (18 out of 24) of the other respondents, report that the frequency for updating their external load models is “other.” It was determined from the survey comments that most of the survey respondents interpreted the “other” category to mean “as needed.” A few respondents answered “infrequently” and “never.”

Respondent	Annually	Monthly	Weekly	Other	**Total**
RCs	4	1	1	11	**17**
Others	5		2	17	**24**
All	9	1	3	28	**41**

Table 4.1-25 — Internal Bus Load Model Update Frequency

Respondent	Annually	Monthly	Weekly	Other	**Total**
RCs	6			11	**17**
Others	5		1	18	**24**
All	11		1	29	**41**

Table 4.1-26 — External Bus Load Model Update Frequency

External Network Models

Table 4.1-27 summarizes the methods used by the survey respondents to determine which power system elements (e.g., buses, lines, transformers, generators, etc.) to include in their external network models. There were 43 respondents to this section of the survey, which includes 17 RC respondents and 26 other respondents.

Methods Used to Determine Power System Elements in the External Model	RC01	RC02	RC03	RC04	RC05	RC06	RC07	RC08	RC09	RC10	RC11	RC12	RC13	RC14	RC15	RC16	RC17	Others	**Total**
Engineering judgment	X	X	X	X	X	X		X	X	X		X	X	X	X	X	X	9	**24**
System planning studies	X	X	X	X			X		X	X								9	**16**
Off-line modeling tools	X	X	X				X	X			X							10	**16**
Other	X	X			X	X												2	**6**
External modeled explicitly				X														2	**3**

Table 4.1-27 — Methods used to Determine External Model Elements

From Table 4.1-27 we see that 59 percent (10 out of 17) of the RCs use multiple methods to determine the elements to include in their external models, and 41 percent (seven out of 17) rely on just one method. Thirty-five percent (6 out of 17) of the RC respondents state that they rely solely on “engineering judgment” to determine the elements to be included in their external models. Thirty-five percent (9 out of 26) of other respondents report that they use “engineering judgment” and/or system planning studies, and 38 percent (10 out of 26) use other off-line modeling tools.

It was very surprising that 35 percent (6 out of 17) of RCs use “engineering judgment” as the sole means of determining what to include in their external models. Seventeen percent (4 out of 24) of the other respondents listed “engineering judgment” as their only means for determining what to include in their external models. Relying solely on engineering judgment to build an external network model is not desirable because it is not always intuitively obvious how much of an interconnection needs to be included in an external model to produce accurate contingency analysis results. Relying entirely on engineering judgment introduces the risk that the external model will be either excessively small or excessively large. If the external model is too small, it can cause erroneous results in real-time contingency analysis, on-line power flow studies, and other applications. If the model is too large, the applications may require significantly more computing resources to arrive at a solution, and the model will require more maintenance resources to keep it current (or it will not be maintained at all).

Table 4.1-28 summarizes the survey results regarding the frequency with which respondents make major changes in their external network models.

Frequency of Major External Model Updates	**RC**	**Others**	**All**
As needed	11	5	16
Annually	3	8	11
N/A		4	4
Infrequently		2	2
Monthly	1	1	2
Depends		1	1
5 years		1	1
Quarterly	1		1
Not done in years		1	1
6-8 weeks	1		1
All	**17**	**23**	**40**

Table 4.1-28 — Frequency of Major External Model Updates

We see that 40 percent (16 out of 40) of the respondents, which includes 65 percent (11 out of 17) of the RC respondents and 22 percent (5 out of 23) of the other respondents, make major changes to their external models as needed. Unfortunately, the survey did not ask them what the average frequency of the “as needed” updates was. Twenty-seven percent (11 out of 40) of the respondents, which includes 18 percent (3 out of 17) of the RC respondents and 35 percent (8 out of 23) of the other respondents, said they make major changes to their external models on an annual basis.

It is difficult to draw any strong conclusions from the responses summarized in Table 4.1-28 except that the external model update frequencies vary widely.

Table 4.1-29 shows the reported starting point for creating (or making additions to) existing external models. There were 41 respondents to this question, including 17 RC respondents and 24 other respondents.

Starting Point for Creating or Adding to the External Model	RC01	RC02	RC03	RC04	RC05	RC06	RC07	RC08	RC09	RC10	RC11	RC12	RC13	RC14	RC15	RC16	RC17	Others	Total
System planning bus/branch model	X	X		X				X	X	X	X	X	X	X	X	X	X	18	**31**
Detailed model from a previous EMS	X	X				X	X											3	**7**
Others				X	X													4	**6**
Detailed EMS model in proprietary non-vendor format	X	X																1	**3**
CIM XML models from the surrounding entities	X	X	X																**3**
Detailed EMS models in proprietary vendor formats	X		X																**2**

Table 4.1-29 — Starting Point for Creating or Making Additions to the External Model

Seventy-six percent (31 out of 41) of respondents, including 76 percent (13 out of 17) of the RC respondents state that the starting point for creating or making additions to their external models is a system planning model (i.e., a bus-branch model with no breaker/switch detail). It is interesting to note that only 3 of the 41 respondents, all of which are RCs, report that the starting point for their external model (or external model additions) was CIM XML[13] models provided by neighboring entities.

CIM XML is not widely used for building and/or maintaining models for a number of reasons. First, the CIM XML modeling language is relatively new and still evolving. Consequently, some entities with older EMSs can only provide model "dumps" in system planning formats (e.g., PSS/E, GE, etc.) or other proprietary EMS vendor formats. Moreover, the use of CIM XML files for building an external model is still problematic because there are few tools, if any, available to merge a CIM XML model with an existing model. The topic of CIM XML will be discussed further in Section 4.2, Modeling Practices and Tools, of this report.

Eighty percent (33 out of 41) of survey respondents, including 100 percent (17 out of 17) of the RC respondents and 67 percent (16 out of 24) of the other respondents, have at least some real-time analog telemetry linked to their external network models. Table 4.1-30 summarizes this information.

[13] CIM XML has been adopted by NERC Data Exchange Working Group (DEWG) to be the format for exchanging models among transmission system operators.

Have Real-time Analogs Linked to External Model?	RCs	Others	All
None		8	8
Some	17	16	33
Total	**17**	**24**	**41**

Table 4.1-30 — Entities with Real-Time Analog Points in their External Models

Seventy-one percent (29 out of 41) of survey respondents, including 82 percent (14 out of 17) of the RC respondents and 63 percent (15 out of 24) of the other respondents, report that they have at least some real-time status point telemetry linked to their external network models. Table 4.1-31 summarizes this information.

Have Real-time Status Points linked to External Model	RCs	Others	All
None	3	9	12
Some	14	15	29
Total	**17**	**24**	**41**

Table 4.1-31 — Entities with Real-Time Status Points in their External Models

It is worth noting that three RC respondents report that they have no real-time status points in their external models.[14]

The average density of real-time analog and status points linked to the external model is reflected by the ratios of analog and status points in the external model to the number of external model buses. These ratios were computed for the survey respondents that provided sufficient information and are shown in Table 4.1-32, Table 4.1-33, Table 4.1-34, and Table 4.1-35.[15]

The low analog-to-bus ratios in the tables (i.e., fewer than 2 analogs per bus for most of respondents) show that many of the buses in these respondents' external models are likely to be measurement unobservable, from a state estimator perspective, without the use of pseudo-measurements. The low external-status-point-to-external-bus ratios for many respondents (i.e., fewer than 1 status point per bus) indicate that many external buses do not have telemetered breaker/switch information, which implies a bus-branch type external model (i.e., a planning model) for many buses. These ratios may explain why many of the respondents state that they will be adding analog and status points to their external models in the coming year.

[14] These RCs were not contacted to verify the accuracy of their responses.

[15] These ratios could only be computed for the survey respondents that provided both the number of external model buses and the numbers of telemetered analog and status points in their external models.

The lack of real-time telemetry data in the external model was one of the contributing factors in the August 2003 blackout. MISO was using a static bus-branch network model in parts of its external model. When the Stuart-Atlanta 345-kV line tripped (monitored by the PJM RC), MISO's state estimator did not know that the line had gone out of service. This led to a data mismatch that prevented MISO's state estimator from computing a solution that could be used by its real-time contingency analysis application. Without real-time contingency analysis, MISO's ability to see that its system was in danger was greatly compromised.[16]

Table 4.1-35 — External-Telemetered-Status-Point-to-External-Bus Ratios for Non-RCs

Table 4.1-36 summarizes the types of analog points used in the external models of the 33 respondents that have analogs in their external models. The respondents include 17 RCs and 16 other respondents.

Analog Types Linked to External Model	RC01	RC02	RC03	RC04	RC05	RC06	RC07	RC08	RC09	RC10	RC11	RC12	RC13	RC14	RC15	RC16	RC17	Others	**Total**
MW	X	X	X	X	X	X	X	X	X	X	X	X	X	X	X	X	X	16	**32**
Mvar	X	X	X	X	X	X	X	X	X	X	X	X	X		X	X	X	16	**32**
KV	X	X	X	X	X	X	X		X	X	X	X	X	X	X	X	X	15	**31**
LTC tap positions	X	X	X	X	X			X										4	**10**
Phase-angle regulating transformer taps				X	X			X										2	**5**
Amps	X						X											2	**4**
Line/TX ratings		X				X													**2**
Others	X		X																**2**

Table 4.1-36 — Analog Types Linked to External Model

From the table we see that the MW, Mvar, and KV analog types were reported used in almost 100 percent of the external models because virtually all state estimators use those measurement types. LTC and phase angle regulating (PAR) transformer tap positions are used to a lesser extent. This is probably because some utilities do not have those types of devices on their transmission grids, which is, in turn, because state estimators provided by most vendors support the use of those types of analogs as inputs. PARs are more commonly seen in the northeastern areas of the Eastern Interconnection to mitigate undesirable flow patterns

Table 4.1-37 summarizes the responses regarding the criteria used to select the analog points that are linked to the external models of respondents that have analog points in their external models. There were 33 total respondents, including 17 RC respondents and 16 other respondents. The respondents overwhelmingly selected “engineering judgment” as the leading analog and status point selection criteria, followed by “all measurements above a certain kV level.” Only 3 respondents, 2 of which were RCs, use analytical tools to determine where measurements are needed.

Analog Selection for External Model	**RC01**	**RC02**	**RC03**	**RC04**	**RC05**	**RC06**	**RC07**	**RC08**	**RC09**	**RC10**	**RC11**	**RC12**	**RC13**	**RC14**	**RC15**	**RC16**	**RC17**	**Others**	**Total**

Off-line observability and/or sensitivity studies	X	X																1	**3**

Table 4.1-37 — Analog Selection Criteria used for External Models

Table 4.1-38 summarizes the responses regarding the criteria used to select the status points that are linked to the external models of respondents that have status points in their external models. There were 29 total respondents, including 14 RC respondents and 15 other respondents. The respondents overwhelmingly selected “engineering judgment” as the leading method for both the analog and status point selection criteria, followed by “all measurements above a certain kV level.” Only 3 respondents, 2 of which were reliability coordinators, use analytical tools to determine where measurements are needed.

Status Point Selection for External Model	RC01	RC02	RC03	RC04	RC05	RC06	RC07	RC08	RC09	RC10	RC11	RC12	RC13	RC14	RC15	RC16	RC17	Others	**Total**

Table 4.1-38 — Status Point Selection Criteria used for External Models

Recommendations for New Reliability Standards

The RTBPTF recommends no new reliability standards for model characteristics because the Real-Time Tools Survey reveals that entities have significantly different practices for creating and maintaining models of the bulk electric system.

Recommendations for New Operating Guidelines

RTBPTF does not recommend developing operating guidelines related to model characteristics.

Areas Requiring More Analysis

RTBPTF identified no areas requiring additional analysis for model characteristics. All recommendations for additional analysis related to modeling issues are presented in Section 4.2, Modeling Practices and Tools.

Examples of Excellence

RTBPTF identified no examples of excellence related to Model Characteristics.

Section 4.2
Modeling Practices and Tools

Definition

The term “modeling practices” as used in the context of this report refers to the processes, procedures, and general methodologies used to build and/or maintain mathematical representations of the power system that are used by real-time applications such as the state estimator, contingency analysis, and on-line power flow. “Modeling tools” are the software applications used to build and/or maintain mathematical representations of the power system. They include any applications supplied by vendors, provided by third parties, or created in house.

Background

The *Outage Task Force Final Blackout Report* [18] identifies a number of modeling deficiencies that contributed to the August, 2003 blackout. For example, because MISO did not link real-time measurements to the external portion of its model, the resulting undetected outage of a key transmission line meant that MISO’s state estimator could not converge. Downstream applications that depend on the state estimator solution could therefore not produce accurate representations of the system condition.

Summary of Findings

RTBPTF considers the implementation of modeling practices and tools to be critical to real-time operations. Therefore, a considerable portion of the Real-Time Tools Survey and subsequent analysis were dedicated to examining the various power system network modeling practices and tools that respondents throughout the industry employ to build and maintain the power system models used by their real-time applications.

This analysis is divided into three subsections: power system model updates, data and information exchange, and modeling tools and utilities. The key findings in these areas are:

- Forty-three percent of all survey respondents, including 53 percent of the RC respondents, model future grid changes by using temporary, fictitious “dummy” switches that allow the new equipment element(s) to be switched into service and/or old equipment elements to be switched out of service when anticipated changes actually take place in the field. The dummy switches are removed on subsequent updates.

---

[18] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April. p. 18.

- Respondents report network model update frequencies ranging from 1- to 12-week intervals. Forty percent of all respondents, including 50 percent of the RC respondents, update their models on a weekly basis.

- Seventy-five percent of all respondents, including 82 percent of the RC respondents, formally document changes and updates to their network models.

- Fifty-six percent of all respondents, including 71 percent of the RC respondents, have some form of documented testing and quality assurance (QA) procedures for their network model changes. Surprisingly, some of the respondents, including a few RCs, place model changes on line with no prior testing.

- Sixty-one percent of all respondents, including 88 percent of the RC respondents, have documented procedures to communicate internal system changes to EMS network modeling personnel.

- Only 35 percent of the survey respondents have formal agreements and/or processes to notify and/or be notified by entities external to their reliability areas about transmission grid changes. Fifty-nine percent of the RC respondents have such processes and procedures. This is surprisingly low, especially for the RCs because of their responsibilities.

- Fifty-five percent of respondents have agreements and procedures for exchanging modeling data with external entities. Fifty-three percent of the RC respondents have such procedures.

- Only 29 percent of survey respondents have model merge utilities, and only 41 percent of the RC respondents have such tools. This means that 59 percent of the RCs have no tools and must use only manual means to incorporate new model additions into their existing models. This highlights a significant need for model merge tools to maintain large power system models.

- Forty-one percent of respondents have network reduction/equivalencing tools, and 47 percent of the RC respondents have these tools. These tools are typically used for external model creation.

- Less than 25 percent of respondents say they have used CIM XML files to either import models from other entities or export their model for use by other entities. Information from the model characteristics section of the survey seems to imply that less that 10 percent of the respondents are using CIM XML files for external model updates.

The subsections that follow present a detailed analysis of the survey data on which the above findings are based.

Power System Model Updates

The survey collected information related to several areas of power system model maintenance, including methods of modeling of future grid changes, the frequency with which production network models are updated, documentation of network model changes, automatic logging of network model changes, QA and testing of network model changes, and testing of changes before they are put on line.

Modeling of Future Grid Changes

Table 4.2-1 summarizes respondents' reported methods of integrating future grid changes into network models in a timely manner. There were 40 respondents, including 17 RC respondents and 23 other respondents.[19]

How Do You Model Future Grid Changes?	RCs	Others	**Total**
Add future elements and "dummy" switches to connect/disconnect future/old equipment	9	8	**17**
Perform an immediate database update on-line to reflect the database changes	5	5	**10**
Perform changes on backup and fail over	3	6	**9**
Perform immediate partial model update on line		4	**4**
All	**17**	**23**	**40**

Table 4.2-1 — Modeling Future Network Model Changes

Respondents chose one of four methods for modeling future network changes. Forty-three percent (17 out of 40) of all respondents, including 53 percent (9 out of 17) of the RC respondents and 35 percent (9 out of 23) of the other respondents, model future grid elements by using temporary "dummy" switches that allow new equipment element(s) to be switched into service and/or the old equipment element(s) to be switched out of service when anticipated changes actually take place in the field. These temporary switches and other elements are subsequently removed when a new database is put in service that incorporates all of the grid changes. Twenty-five percent (10 out of 40) of respondents, including 29 percent (5 out of 17) of the RC respondents and 22 percent (5 out of 23) of the other respondents, perform immediate database updates on line to reflect the addition/removal of equipment in the field when the equipment is actually placed into/out of service. Twenty-two percent (11 out of 40) of the respondents, including 18 percent (3 out of 17) of the RC respondents and 26 percent (6 out of 23) of the other respondents, make the changes in their backup system databases and then fail over to the new database when the

[19]Respondents without models were not included in the table.

equipment in the field goes into or out of service. Ten percent (4 out of 40), including 0 percent (0 out of 17) of the RC respondents and 17 percent (4 out of 23) of the other respondents, perform immediate partial model updates on line.

The respondents' choices of methods appear to depend largely on their EMSs' database modeling capabilities (i.e., features provided by the EMS vendor) and the sizes of their databases. Respondents that have on-line database-change capabilities use them (see the "Modeling Tools and Utilities" subsection below). Respondents without on-line database editing capabilities use one of the other two methods identified in Table 4.2-1; the majority of RC respondents without on-line editing capabilities favor the "dummy switch" approach for modeling future system changes.

Frequency of Network Model Updates

Table 4.2-2 summarizes the survey responses regarding frequency of production network model updates. There were a total of 40 respondents to this question, including 16 RC respondents and 24 other respondents.

Network Database Update Frequency	RC	Others	Total
Weekly	8	8	**16**
3 Weeks	2	3	**5**
Monthly	2	4	**6**
6 Weeks	1		**1**
12 Weeks	3	2	**5**
As needed		7	**7**
Total	**16**	**24**	**40**

Table 4.2-2 — Production Network Model Update Frequency

Respondents report network model update frequencies ranging from 1- to 12-week intervals, with unscheduled updates performed "as needed." Forty percent (16 out of 40) of the respondents, including 50 percent (eight out of 16) of the RC respondents and 33 percent (8 out of 24) of the other respondents, update their models weekly. Twenty-eight percent (11 out of 40) of respondents, including 25 percent (4 out of 16) of the RC respondents and 29 percent of the other respondents, update their models every 3 to 4 weeks. Respondents with markets report less frequent updates, most likely because of the complexities of market-related applications, the larger model sizes, and the associated auditing requirements.

Documentation of Network Model Changes

Table 4.2-3 summarizes the survey responses regarding documentation of network model changes. There were 40 respondents to this question, including 17 RC respondents and 23 other respondents.

Are Network Model Changes and Updates Formally Documented?	RC	Other	All
No	3	7	10
Yes	14	16	30
Totals	**17**	**23**	**40**

Table 4.2-3 — Formal Documentation of Network Model Changes

Seventy-five percent (30 out of 40) of the respondents, including 82 percent (14 out of 17) of the RC respondents and 70 percent (16 out of 23) of the other respondents, formally document the changes and updates made to their network models. All RCs that operate in markets formally document their network model changes, as would be expected.

Automatic Logging of Network Model Changes

Table 4.2-4 summarizes the survey responses regarding the automatic logging of network model changes. There were 40 respondents to this question, including 17 RC respondents and 23 other respondents.

Are Network Model Changes Automatically Logged by Modeling Tools?	RC	Other	All
No	11	18	29
Yes	6	5	11
Totals	**17**	**23**	**40**

Table 4.2-4 — Automatic Logging of Network Model Changes

Only 27 percent (11 out of 40) of respondents, including 35 percent (6 out of 17) of the RC respondents and 22 percent (5 out of 23) of the other respondents, have modeling tools that automatically log changes made to their network models. The responses summarized in Table 4.2-3 and Table 4.2-4 seem to imply that those that document network model changes do so largely manually.

Quality Assurance and Test Procedures for Network Model Changes

Table 4.2-5 summarizes survey responses related to documented model testing and quality assurance (QA) procedures. There were 39 respondents for these questions, including 17 RC respondents and 22 other respondents.

Has documented model change testing & QA procedures	RC	Other	All
No	5	12	17
Yes	12	10	22
Totals	**17**	**22**	**39**

Table 4.2-5 — Documented Model Testing and QA Procedures

Fifty-six percent (22 out of 39) of respondents, including 71 percent (12 out of 17) of the RC respondents and 45 percent (10 out of 22) of the other respondents, indicate that they have some form of documented testing and QA procedures for their network model changes. All of the RC respondents that operate in markets have these procedures, as one would expect. It is surprising that 29 percent (5 out of 17) of the RC respondents have no documented network model testing and quality assurance procedures.

Testing Model Changes Prior to Putting Model On-Line

Table 4.2-6 summarizes the survey responses related to testing network models before placing them on line in the production environment. There were a total of 39 respondents to these questions, including 17 RC respondents and 22 other respondents.

Model Change Testing Methodologies	RC01	RC02	RC03	RC04	RC05	RC06	RC07	RC08	RC09	RC10	RC11	RC12	RC13	RC14	RC15	RC16	RC17	Others	Total
Development EMS with live data	X	X	X	X	X	X	X	X	X	X	X	X						10	**22**
Development EMS with no live data	X	X	X										X	X	X			1	**7**
Place on line with no tests, verify on-line																X	X	11	**13**
Test on a DTS						X												4	**5**
Use study power flow and/or study contingency analysis to test changes					X														**1**
Test using off-line model															X				**1**
Test on backup system using real-time telemetry				X															**1**

Table 4.2-6 — Model Change Testing Methodologies

Fifty-six percent (22 out of 39) of respondents, including 71 percent (12 out of 17) of the RC respondents and 45 percent (10 out of 22) of the other respondents, test their network models on a development (i.e., test bed) system that allows testing with live SCADA data. Only 33 percent (13 out of 39) of respondents, including 12 percent (2 out of 17) of the RC respondents and 50 percent (11 out of 22) of the other respondents, place their model changes on the production system with no testing prior to putting the models on line. They test their models on line after they are put into production.

A higher percentage of RCs than other respondents perform testing with live data on a development system prior to putting their models on-line. However, considering the function and responsibilities of RCs, one might expect an even higher percentage. Eighty-eight percent (15 out of 17) of the RC respondents perform some type of model testing prior to putting models on line. However, 3 of these respondents do not use live SCADA data in their testing.

Data and Information Exchange

The subsections below present the survey results for data and information exchange processes and procedures.

Processes and Procedures for Communicating Planned and Actual Internal System Transmission Grid Changes to Modeling Personnel

Table 4.2-7 summarizes the survey responses regarding "processes and procedures for communicating planned and actual internal system changes to EMS modeling personnel." The "internal system" refers to the portion of the grid for which the survey respondent has responsibility (i.e., the respondent's reliability footprint). There were a total of 41 respondents to this question, including 17 RC respondents and 24 other respondents.

Has Formal Notification Process for Internal System Changes	RC	Other	**All**
No	2	14	**16**
Yes	15	10	**25**
Totals	**17**	**24**	**41**

Table 4.2-7 — Has Formal Notification Processes for Internal Grid Changes

Sixty-one percent (25 out of 41) of the respondents, including 88 percent (15 out of 17) of the RC respondents and 42 percent (10 out of 24) of the other respondents, have documented procedures to communicate internal system changes to EMS network modeling personnel. The percentage of RCs with these procedures is significantly higher than the percentage of respondents who are not RCs. This is probably because:

- RCs typically have larger systems and thus larger models to maintain, so they need a more structured approach for learning about changes.
- Many RCs do not own some (or even any) of the transmission assets in their reliability footprint. Consequently, they are very dependent on the asset owners to provide them information on when things are changed in the field.

Table 4.2-8 summarizes the value for situational awareness that the respondents place on these procedures by those that actually have them.

Value of Internal Grid Change Notification Procedures	RC	Other	All
Essential	13	8	**21**
Desirable	1		**1**
Minimal Value	1		**1**
No Value		1	**1**
Totals	**15**	**9**	**24**

Table 4.2-8 — Value of Internal Grid Change Notification Procedures

Eighty-eight percent (21 out of 24) of the respondents that have these procedures, including 87 percent (13 out of 15) of the RC respondents and 89 percent (8 out of 9) of the other respondents, consider them "essential" for situational awareness. Only one RC respondent indicates that its procedures were of "minimal" value. Eight out of 9 of the non-RC respondents that have documented procedures stated that these procedures are "essential."

A high percentage of the RC respondents (88 percent, 15 out of 17) have procedures for communicating to EMS support staff any changes in internal grids. This is not surprising because many RCs own only a fraction of the transmission assets in their reliability footprint and are therefore dependent on the asset owners to report when changes have been made and/or when they are going to occur. All of the RCs that operate in markets have these types of procedures.

Processes and Procedures for Communicating Planned and Actual Transmission Grid Changes with External Entities

Table 4.2-9 summarizes the survey responses regarding documented "processes and procedures for communicating planned and actual system changes with external entities." The "external system" refers to that portion of the grid that is not in the respondent's reliability area of responsibility (e.g., outside the RC or TOP system footprint). There were a total of 40 respondents for this question, which included 17 RC respondents and 23 other respondents.

Formal Notification Processes and Procedures with External Entities on Planned Grid Changes	RC	Other	All
No	7	19	**26**
Yes	10	4	**14**
Totals	**17**	**23**	**40**

Table 4.2-9 — Formal Notification Processes and Procedures with External Entities for Planned Grid Changes

Table 4.2-10 indicates the value for situational awareness placed on these procedures by the respondents that have them.

Value of Formal Notification Processes and Procedures with External Entities on Planned Grid Changes	RC	Other	**All**
Essential	7	1	**8**
Desirable	3	2	**5**
Minimal Value		1	**1**
No Value		1	
Totals	**10**	**4**	**14**

Table 4.2-10 — Value of formal Notification Processes and Procedures with External Entities

From Table 4.2-10 we see that only 35 percent (14 out of 40) of the survey respondents have formal agreements and/or processes to notify and/or be notified by entities external to their reliability area regarding planned and actual changes to the physical transmission grid. This includes 59 percent (10 out of 17) of the RC respondents and 17 percent (4 out of 23) of the other respondents.

Of those that have these procedures, 57 percent (8 out of 14) of the respondents, which includes 70 percent (7 out of 10) of the RC respondents and 25 percent (1 out of 4) of the other respondents, consider them "essential."

Maintaining a current and accurate external network model to support contingency analysis and a wide-area view would, at a minimum, appear to require processes and procedures for knowing about major changes in external transmission systems. But many of the survey respondents, including a significant number of RCs, do not have such procedures. It should be noted that the NERC DEWG has written procedures for notifying other RCs, TOPs, and similar entities about upcoming changes in the power grid. However, these procedures are neither enforced nor strictly followed. The "Planned Power System Model Change Notification Process" document can be downloaded from the DEWG section of the NERC website (http://www.nerc.com/~filez/isn.html).

Processes and Procedures for Communicating EMS-Related Changes to External Entities

Table 4.2-11 summarizes the survey responses regarding "processes and procedures for communicating planned and actual EMS-related changes with external entities." "EMS-related changes" are changes related to EMS databases, networks, and other components that can affect entities that receive/send data from/to them. Examples of such changes are addition and/or deletions of new SCADA points, alterations related to communication links (e.g., IP address changes), changes to ICCP object IDs, etc. There were a total of 40 respondents to this question, which included 16 RC respondents and 24 other respondents.

Have Formal Notification Processes and Procedures with External Entities on Planned and Actual EMS Change Notification	RC	Other	All
No	7	18	**25**
Yes	9	6	**15**
Totals	**16**	**24**	**40**

Table 4.2-11 — Processes and Procedures for Communicating EMS-Related Changes to External Entities

Table 4.2-12 summarizes the value for situational awareness of the processes and procedures for those respondents that have them.

Value of Formal Notification Processes and Procedures with External Entities on Planned and Actual EMS Change Notification	RC	Other	All
Essential	7	2	**9**
Desirable	2	2	**4**
Minimal Value		2	**2**
No Value			
Totals	**9**	**6**	**15**

Table 4.2-12 — Value of Processes and Procedures to Communicate EMS Changes with External Entities

Table 4.2-12 indicates that 40 percent (16 out of 40) of respondents, including 56 percent (9 out of 16) of the RC respondents and 25 percent (6 out of 24) of the other respondents, have processes and procedures for notifying external entities about EMS-related changes. Of the 16 respondents that have these procedures, 87 percent (13 out of 15) consider them either “desirable” or “essential” for situational awareness. All (9 out of 9) of the RC respondents that have EMS change notification procedures state that these procedures are either “essential” or “desirable” for situational awareness. Sixty-seven percent (4 out of 6) of the other respondents that have these procedures stated that they were either “essential” or “desirable.”

It is surprising that only 9 RC respondents have these procedures because they are more likely than the other respondents to acquire real-time SCADA information from external EMS systems to support their wide-area models. However, this finding is consistent with the model information that was discussed in Section 4.1, Model Characteristics, of this report (e.g., the computed external-measurement-to-external bus ratios). However, we see from the survey responses that all 9 of the RCs who have these procedures consider them desirable or essential.

The NERC DEWG has written “*ISN Node Responsibilities and Procedures*,*”* which includes procedures that should be followed by entities that exchange real-time data via the ISN. Procedures include notification of server outages, software upgrades, data changes, and other related items. These procedures are not strictly enforced, however.

Agreements and Procedures for Exchanging Transmission Model Data with External Entities

Table 4.2-13 summarizes the survey responses regarding “agreements and procedures for exchanging transmission modeling data with external entities.” There were 40 respondents to these questions, which included 17 RC respondents and 23 other respondents.

Transmission modeling data include typical network model information (e.g., breaker and switch connectivity data, line and transformer parameters, generating unit parameters, etc.) in addition to supporting information such as station schematics, geographic maps, etc.

Has Formal Agreements and Procedures for Exchanging Modeling Information with External Entities	RC	Other	**All**
No	8	10	**18**
Yes	9	13	**22**
Totals	**17**	**23**	**40**

Table 4.2-13 — Agreements and Procedures for Exchanging Modeling Information with External Entities

The survey responses indicate that 55 percent (22 out of 40) of respondents, including 53 percent (9 out of 17) of the RC respondents and 57 percent (13 out of 23) of the other respondents, have agreements and procedures with external entities for exchanging modeling data.

The number of respondents with agreements and procedures for exchanging modeling information with external entities is surprisingly low, especially for the RCs. It would seem that RCs would need such procedures in place to help maintain the larger models required for their wide-area view.

Table 4.2-14 summarizes the value for situational awareness placed on data-exchange agreements with external entities by the 21 respondents that have such agreements.

Value of Formal Agreements and Procedures for Exchanging Modeling Information with External Entities	RC	Other	All
Essential	5	3	**8**
Desirable	4	4	**8**
Minimal Value		1	**1**
No Value		4	**4**
Totals	**9**	**12**	**21**

Table 4.2-14 — Value of Formal Data Exchange Agreements with External Entities

From the responses we see that 76 percent (16 out of 21) of those that have these procedures, including 100 percent (9 out of 9) of the RC respondents and 58 percent (7 out of 12) of the other respondents, think these procedures are either “essential” or “desirable” for situational awareness.

Modeling Tools and Utilities

“Modeling tools,” as defined in this report, are software applications used to build and/or maintain power system models. They include any applications supplied by vendors, provided by third parties, or created in-house. The subsections below summarize the results for the modeling tools portion of the Real-Time Tools Survey.

On-line Database Editing Capabilities

Table 4.2-15 summarizes the survey respondents’ on-line SCADA data editing capabilities. There were 43 respondents to this question, which included 17 RC respondents and 26 other respondents. Fifty-six percent (24 out of 43) of respondents, which included 65 percent (11 out of 17) of the RC respondents and 50 percent (13 out of 26) of the other respondents, have some form of on-line SCADA data editing capabilities in their EMSs.

Can you Edit existing SCADA Model Information Online?	RC	Other	All
No	6	13	**19**
Yes	11	13	**24**
Total	**17**	**26**	**43**

Table 4.2-15 — On-Line SCADA Database Editing Capability

Table 4.2-16 summarizes the value for situational awareness that respondents with on-line SCADA data editing place on this capability.

How do You Rank the Value of this On-line SCADA Editing Capability as Applied in Your Modeling Activities?	RC	Other	**All**
Essential	6	6	**12**
Desirable	4	5	**9**
Minimal Value	1	2	**3**
No Value			
Total	**11**	**13**	**24**

Table 4.2-16 — Value of On-Line SCADA Model Editing Capability

From Table 4.2-16 we see that 88 percent (21 out of 24) of the respondents that have on-line SCADA model editing capability, including 91 percent (10 out of 11) of the RC respondents and 85 percent (11 out of 13) of the other respondents, that have this capability think that it is either "desirable" or "essential" for situational awareness. Only 12 percent (3 out of 24) of respondents that have this feature, which included 1 RC and 2 other respondents, felt that this feature adds minimal value.

In general, on-line SCADA data editing capability is a feature that would only be provided by an EMS vendor as part of its proprietary database support tools. This is not a feature that one would expect to be implemented in house by EMS support personnel.

Table 4.2-17 summarizes the on-line network model data editing capabilities of the survey respondents. There were 40 respondents to this question including 16 RC respondents and 24 other respondents.

Can You Edit Network Model Database Information Online?	RC	Other	**All**
No	6	14	**20**
Yes	10	10	**20**
Total	**16**	**24**	**40**

Table 4.2-17 — On-Line Network Model Database Editing Capability

Table 4.2-17 indicates that 50 percent (20 out of 40) of the respondents, including 63 percent (10 out of 16) of the RC respondents and 42 percent (10 out of 24) of the other respondents, have on-line network model editing capabilities on their EMS. As with on-line SCADA data editing, on-line network modeling is almost exclusively a feature provided only by EMS vendors. This is not a feature that one would expect to be implemented in house by EMS support personnel.

Unfortunately, the Real-Time Tools Survey was not specific about the meaning of "on-line database editing." For instance, the survey did not differentiate among "add," "modify," and "delete" capabilities. Many EMS tools allow modification of existing data items (e.g., changing SCADA limits, line impedances or limits), but do not allow the addition or deletion of new items. Consequently, 2 survey respondents that both have on-line database editing could have answered this question in opposite ways, depending on what they interpreted it as covering.

Supplemental Model Validation Tools

Table 4.2-18 summarizes survey responses related to supplemental database validation tools. Supplemental database validation tools are applications that provide EMS database error and consistency checking above and beyond what the EMS vendor provides in its standard product. There were a total of 42 respondents to this question that included 17 RC respondents and 25 other respondents.

Supplemental Database Validation Tools	RC	Other	**All**
No	6	20	**26**
Yes	11	5	**16**
Totals	**17**	**25**	**42**

Table 4.2-18 — Supplemental Database Validation Tools

Thirty-eight percent (16 out of 42) of the respondents, including 65 percent (11 out of 17) of the RC respondents and 20 percent (5 out of 25) of the other respondents, have supplemental database validation tools. Significantly more RC respondents have these types of utilities compared to other respondents. This is probably because the RCs are generally larger organizations than other respondents and may have more support staff to develop such tools. Additionally, RCs generally have larger network models and more data to maintain.[20] Consequently, RCs have a greater need for such tools and can justify the resources required.

Network Model Merge Tools

Network model merge utilities allow users to merge a partial or full network model with an existing network model. These types of utilities are needed to facilitate activities such as replacing an existing external network model with a new one. Table 4.2-19 summarizes the survey respondents' model-merge capabilities.

Has Network Model Merge Tools	RC	Other	All
No	10	20	**30**
Yes	7	5	**12**
Totals	**17**	**25**	**42**

Table 4.2-19 — Network Model Merge Tools

There were 42 respondents to this question, including 17 RC respondents and 25 other respondents. Only 28 percent (12 out of 43) of the respondents, which

[20] RC respondents average almost twice as many buses and branches in their network models as do the other survey respondents.

include 41 percent (7 out of 17) of the RC respondents and 20 percent (5 out of 15) of the other respondents, have network model merge utilities.

The fact that 59 percent (10 out of 17) of the RC respondents do not have model merge tools suggests that there is a significant need for tools to maintain large power system models. This implies that many of the RCs are required to maintain their internal and external models more or less manually. For instance, if a new balancing authority is added to an RC's existing footprint and the RC does not have model merge utilities, it has the tedious task of manually adding the detailed model of the new balancing authority to the existing network model. This is a significant issue because many RCs and others are expanding the sizes of their internal and/or external models to enhance their wide-area views.

Network Reduction/Equivalencing Tools

Network reduction and equivalencing utilities are applications that take a given network model as input and generate a smaller reduced and/or equivalent model using network reduction algorithms and the user's specific input instructions on what power system elements to preserve, etc. This type of tool is particularly useful when building the external portion of a network model using network models from other entities (e.g., a model of the interconnection) as a starting point. Table 4.2-20 summarizes the survey responses related to these types of tools. There were a total of 42 respondents to these questions, including 17 RC respondents and 25 other respondents.

Has Network Reduction and Equivalencing Tools?	RC	Other	All
No	9	16	**25**
Yes	8	9	**17**
Totals	**17**	**25**	**42**

Table 4.2-20 — Network Reduction/Equivalencing Tools

Table 4.2-20 indicates that 40 percent (17 out of 42) of respondents, including 47 percent (8 out of 17) of the RC respondents and 36 percent (9 out of 25) of the other respondents, have network reduction/equivalencing tools.

These results suggest that 53 percent of the RC respondents and 64 percent of the other respondents do one of the following:

- use a model of the external world that is not simplified in any way
- use an external model that was generated using “engineering judgment” to determine the buses, lines, and other elements
- have a third party build an external model for them
- have no external model

The responses from the model characteristics section of the survey suggest that many of the respondents that do not have network reduction tools are relying on “engineering judgment” to select the elements to keep in their external models.

Table 4.2-21 summarizes the responses to the question for respondents that have network reduction/equivalencing tools, “Do you use these tools?”

Do You Use Network Reduction and Equivalencing Tools?	RC	Other	All
No	3	2	**5**
Yes	5	7	**12**
Totals	**8**	**9**	**17**

Table 4.2-21 — Use of Network Reduction/Equivalencing Tools by those that Have Them

Seventy-one percent (12 out of 17) of the respondents that have these tools, including 63 percent (5 out of 8) of the RC respondents and 78 percent (7 out of 9) of the other respondents, actually use them. Those that do not use them probably rely on engineering judgment when creating their external models.

CIM XML Export/Import Capabilities and Usage

Tables 4.2-22, 4.2-23, and 4.2-24 summarize the survey responses regarding CIM XML import/export capabilities and usage. There were a total of 41 respondents to this set of questions, which included 17 RC respondents and 24 other respondents (see Table 4.2.22).

Do You Have CIM XML Import/Export Capabilities?	RC	Other	**All**
No	8	16	**24**
Yes	9	8	**17**
Total	**17**	**24**	**41**

Table 4.2-22 — CIM XML Import/Export Capability

The responses show that 41 percent (17 of 41) of the respondents, including 53 percent (9 out of 17) of the RC respondents and 33 percent (8 out of 24) of the other respondents, have CIM import/export capability. The 17 respondents that have this capability were asked if they use it. Their responses are summarized in Table 4.2-23 below.

Do You Use Your CIM XML Import/Export capability?	RC	Other	**All**
No	3	4	**7**
Yes	6	4	**10**
Totals	**9**	**8**	**17**

Table 4.2-23 — Use of CIM XML Import/Export Capability by those that Have It

The response data in Table 4.2-23 shows that 59 percent (10 out of 17) of the respondents that have CIM XML import/export capability, including that 66 percent (6 out of 9) of the RC respondents and 50 percent (4 out of 8) of the other respondents, actually use it for importing and/or exporting models in CIM XML format.

Unfortunately, the survey did not specifically ask the respondents if they were using this capability for importing models, exporting models, or both. However, in Section 4.1, Model Characteristics, only 3 respondents, all of which are RCs, said they use CIM XML models as the starting point for building their external models, which would require importing CIM XML models. Conversely, this seems to imply that 7 of the 10 respondents that use their CIM XML import/export capability are using it to export models (perhaps to send to others to use?) and not to import them.

The 10 survey respondents who said they used CIM import/export capability were asked to rank the value of this capability. Table 4.2-24 summarizes the responses to this question.

How Do You Rank the Value of CIM XML File Import/Export as Applied in Your Modeling Activities?	RC	Other	All
Essential	1	3	**4**
Desirable	3	3	**6**
Minimal			
No Value			
Totals	**4**	**6**	**10**

Table 4.2-24 — Value of CIM XML Import/Export by Those that Actually Use It

From Table 4.2-24 we see that all 10 of the respondents who use CIM XML import/export capability say that it is either an “essential” or “desirable” feature as applied to their modeling activities. Only 1 of the 4 RC respondents said it was “essential,” and 3 of the 6 non-RC respondents said it was “essential.”

These “value” responses seem inconsistent when coupled with the fact that only 3 of the 10 respondents say that they use CIM XML imports as the starting point of their external models. (All 3 were RCs.) It may be that those that use the capability only to export models say it is essential because they are required to provide CIM XML models to others (e.g., their RCs). Or, it could be that the respondents placed a high value on this capability because CIM XML will very likely be the model exchange language of the future and they have plans to use it. Unfortunately, the survey questions related to CIM XML were not as thorough and concise as they could have been.

In an attempt to better understand the apparent inconsistencies in the survey responses, the task force contacted for follow-up questions 3 of the respondents that have used their CIM XML import/export capabilities in their modeling activities. All of those contacted were RCs who have some of the largest network models in the survey. Two of the 3 had used CIM XML models that were provided to them by other entities for major internal and external model additions and replacements, and one has just used a CIM XML model for internal model updates. Some of the interesting pieces of information that came from the follow-up questions are summarized below:

- CIM XML files have been used infrequently and only for major model additions and replacements. None of the 3 had used it for relatively small changes (e.g., incremental updates) that would be considered as “routine” model maintenance.
- It is not a “plug and play” process and generally takes weeks or months to implement changes. For instance, one respondent stated that some CIM XML files require one to two weeks to complete the import, conversion, and some basic model validation. When there is a problem with the source CIM XML file (because of data, syntax, or schema), they must request an updated version of the source model. Every request for an updated source model and the subsequent import/conversion requires two

to three weeks, so multiple requests for an updated source model can easily add three months (or more) to a project before the model reduction and model merge steps can even begin.

- Merging a CIM XML model into an existing network model is an involved process that entails both automated and manual work. The respondents have had to write special software tools to aid in their efforts.
- Some entities cannot dump their models in CIM XML output files to other entities because their EMSs do not have that capability. In that case, the receiving entities must accept files in other formats and use them to update their models.
- None of those contacted has used the CIM XML models for measurement mapping. This has done manually or by supplemental data files and tools that were created for that purpose.
- The import of the CIM XML model does not provide 100 percent of what is needed for a complete model. Custom programming and/or manual data entry is often needed to populate missing or incorrect data in the source model.

Some of the major technical issues that the respondents said they had to overcome were:

- CIM XML files do not always comply with the NERC CPSM.
- There is some room for interpretation of the CIM standard, and, as a result, certain data are not put in the data classes or attributes where another vendor would expect to find them.
- Vendor tools are not always compatible with the exact version of CIM that was used to create the source model.
- Attempts to resolve data issues by browsing XML files are nearly impossible because the files are difficult to read. Better tools are needed to review the CIM XML files for troubleshooting.
- CIM XML files are extremely large. The large file sizes stress (and sometimes break) the tools that are used to import and convert the models.

The CIM definition for power system modeling is still under development and is evolving. Most of the major EMS vendors are participating in interoperability tests to work out the existing bugs and to test new features (e.g., incremental updates). There is also an active users group that has been created to develop the CIM related standards (http://www.cimusers.org). However, despite the push in the industry to adopt and use CIM XML, the survey responses suggest that CIM XML model exchange is not yet common practice. Only 42 percent (17 out of 41) of the respondents can even export their models in CIM XML files. And only 58 percent (10 out of 17) of those that have it, and 24 percent (10 out of 41) of all survey respondents, are using it at all. Despite these challenges, the respondents that were contacted expect to be using CIM XML to a greater extent in the future as technical problems are solved and users and EMS vendors create new tools.

Recommendations for New Reliability Standards

RTBPTF makes no recommendations at this time for reliability standards related to modeling practices. However, RTBPTF recommends that additional analysis be done in several modeling areas from which recommendations for new reliability standards may be forthcoming.

Recommendation – A16

Investigate processes and procedures for internal system update and external data exchange, including CIM XML models.

Areas Requiring More Analysis

RTBPTF has identified the following areas for more analysis:

- Clarity of fundamental definitions of terms used in the existing NERC reliability standards
- Processes and procedures for grid change notification and data exchange
- Development of external system modeling guidelines
- Exchange of CIM XML models

Clarity of Fundamental Definitions

RCs and other entities have been charged with monitoring their "bulk electric systems" and having network models that provide a "wide-area view." However, existing definitions of "bulk electric system," "bulk power system," and "wide-area view" are vague and open to interpretation as evidenced by the significant variation in models reported in the Real-Time Tools Survey. An entity's interpretation of these definitions can significantly impact the size and contents of the network model it uses for its real-time applications, and, consequently, the maintenance efforts needed to keep that model current. The vagueness of these terms may partially explain some of the large differences in model sizes and characteristics that were identified in Section 4.1, Model Characteristics, (e.g., external-bus-to-total-bus ratios, etc.). NERC should clearly define these terms because their potential impact on network modeling decisions.[21] For more discussion of the need to define these terms, please see the Introduction to this report and Section 2.2, Visualization Techniques.

[21] Lack of specificity in these terms was also pointed out in the *FERC Staff Assessment*.

Recommendation – I5

Develop system models and standards for exchange of model information.

Grid Change Notification and Model Data Exchange

The power system models used to provide a wide-area view can require extensive modeling both inside and outside the reliability footprint of an RC or TOP. The external portions of the models are often more difficult to maintain than the internal portions because of the problems related to 1) knowing when something in the grid external to the reliability footprint has changed or is going to change (e.g., a new line or station is added) and 2) being able to obtain required modeling and real-time data from external entities.

As noted in the analysis above related to notification and other procedures among reliability entities, updating of external models is greatly facilitated when there are processes and procedures in place to:

- Prescribe how entities notify each other about pending grid changes far enough in the future to allow updating of real-time network models in a timely manner; and
- Identify the types of data (both real-time and modeling) that are to be exchanged, the time frames for data exchange, acceptable data exchange media and formats, required non-disclosure agreements, etc.

Many survey respondents have at least some data exchange/update processes and procedures in place with entities within their reliability footprints (i.e., their internal model areas), but few if any have such procedures in place for all of the external entities that border and/or have significant impact on their reliability footprints.

RTBPTF recommends that a task force be created to investigate grid change notification and real-time model and ICCP data-exchange processes and procedures. This task force would identify and recommend minimum standards for real-time models and data exchange similar to some of the existing “MOD” standards related to steady-state models (e.g., MOD-010, MOD-011, etc.) but more appropriate for the types of models and supplemental information required by real-time EMS applications such as the state estimator and contingency analysis. The task force should address the following:

- Grid change notification processes and procedures,
- Real-time data exchange (i.e., ICCP data) processes and procedures (a good foundation for these procedures can be found in the documents posted on the NERC DEWG website.)

- Model data exchange processes and procedures (network models and other information needed to support these models such as station schematics, regional maps, etc.), and
- Any required legal agreements needed to facilitate information exchange (non-disclosure, etc.).

External Model Development

It is evident that survey respondents have used a wide range of approaches to create external models and determine what measurements to include in them. Some external models appear to be excessively large and some excessively small, relative to the sizes of the entire models of which they are a part. Some external models contain many real-time analog and status measurements, and some have few or none.

Based on these observations, RTBPTF recommends that a task force be created to focus specifically on external models used to support real-time applications. This task force would be charged with defining guidelines and/or minimum requirements related to external modeling. The areas addressed should include, but are not be limited to:

- The level of external model detail needed to support accurate real-time contingency analysis solutions
- Methods for determining which buses, branches, and other elements to include in an external model for a given internal model
- Methods for determining the real-time analog and status measurements to be included in the external model (i.e., the level of measurement observability)
- Methods for exchanging modeling data and the data-exchange format(s) to use. This includes network model and other supporting information (e.g., station one-line diagrams)
- Methods for maintaining and updating external models
- Identification of tools needed to create and maintain an external model (CIM XML editing tools, model merge tools, reduction/equivalencing tools, etc.).

CIM XML Model Exchange

Based on the Real-time Tools Survey responses and supplemental information collected in follow-up discussions with selected respondents, it appears that some technical issues need to be resolved before the use of power system modeling data contained in CIM XML files becomes commonplace. To date, the few entities that have used CIM XML model dumps in their maintenance activities report in follow-up comments that they have found it to be a challenging exercise. Some current technical issues include:

- Problems are caused by different EMS vendor interpretations of the CIM standard.

- Vendor tools are not always compatible with the exact version of CIM used to create a source model.
- CIM XML files are generally very large. These large files sometimes stress (and sometimes break) the tools that are used to manipulate them.
- Resolving data issues by browsing XML files is difficult because these files cannot easily be read, unlike other model formats such as PSS/E, simple flat files, etc.
- Support tools to manipulate CIM models (e.g., network reduction utilities) are lacking. This is important because most users will not want to incorporate an entire model they receive from another entity (e.g., they may want to strip out the lower voltages).

Despite these and other problems, it is generally believed that CIM XML files will eventually be the preferred format for exchanging power system model data once the major technical issues are addressed.

RTBPTF recommends a review of the current state of CIM XML model exchange to determine in detail where and how this format is being used, identify known problems, and make recommendations about how the industry should proceed with CIM XML model exchange. Short-term model data exchange solutions to use in the interim should also be investigated and identified.

Recommendations for Operating Guidelines

RTBPTF does not recommend developing operating guidelines related to modeling practices and tools.

Areas Requiring More Analysis

RTBPTF identified no areas requiring additional analysis for modeling practices and tools.

Examples of Excellence

RTBPTF identified no examples of excellence related to modeling practices and tools.

Section 5.0
Support and Maintenance Tools

Introduction

RTBPTF believes that tools and applications for support and maintenance of real-time tools help enhance operator situational awareness. If real-time tools are not supported and maintained, performance measures such as application availability, data integrity, and application solution quality can be compromised without operators knowing. In addition, the equipment (i.e., servers, data links) needed to run real-time tools should be monitored and maintained to preserve the integrity and availability of the real-time tools.

Proper support and maintenance require that support and maintenance personnel have access to the tools/applications that keep real-time tools running. These are also the tools/applications that inform the operator of the availability status of essential real-time tools and thereby contribute to operator situational awareness.

RTBPTF analyzed five support and maintenance tools: display maintenance tools, change management tools and practices, facilities monitoring tools, critical applications monitoring tools, and trouble reporting tools. RTBPTF's analysis and recommendations for each of these tools are presented in Sections 5.1 through 5.5.

Section 5.1, Display Maintenance Tool — A tool/application used by support personnel to develop and maintain power system displays used by operators to monitor, assess, or perform the actions necessary to maintain the reliability of the bulk electric system. Power system displays enhance operator situational awareness.

Section 5.2, Change Management Tools and Practices — Tools/applications used by support personnel to maintain, modify, and/or test critical equipment and/or critical real-time tools[1] that operators use to monitor, assess, or perform the actions necessary to maintain the reliability of the bulk electric system. The practices and processes of support personnel are also discussed this section.

Section 5.3, Facilities Monitoring — Tool/applications that monitor the status of computer systems equipment, servers, backup systems, communications systems, networks, and other critical facilities, etc. This tool allows operators and support personnel to maintain awareness of critical equipment issues that may affect the availability of critical real-time tools used to operate and monitor the bulk electric system.

Section 5.4, Critical Applications Monitoring — Tools/applications that monitor the status of critical real-time tools. These tools allow operators and support personnel to maintain awareness of the availability status of critical real-time tools. Critical real-time tools must be available for operators to monitor, assess, and perform the necessary actions necessary to maintain the reliability of the bulk electric system.

---

[1] See the Terminology subsection below for an explanation of the terms "critical equipment" and "critical real-time tools."

Section 5.5, Trouble-Reporting Tool — An application that allows control center tool users (i.e. operators and support personnel) to enter trouble reports (e.g., application problems, system problems, display problems, etc.) so that problems and their resolutions are documented and tracked.

Terminology

RTBPTF introduces two new terms in Section 5 to facilitate discussions and recommendations. The new terms are built on current definitions approved in the NERC Cyber Security Standards, CIP-002 through CIP-009, which were developed by the electric industry to improve the security of cyber assets critical to the reliable operation of the North American bulk electric system. The standards were approved by the NERC BOT on May 2, 2006, and became effective on June 1, 2006. The Cyber Security Standards define the following terms:

- Critical Assets — Facilities, systems, and equipment which, if destroyed, degraded, or otherwise rendered unavailable, would affect the reliability or operability of the bulk electric system.
- Cyber Assets — Programmable electronic devices and communication networks including hardware, software, and data.
- Critical Cyber Assets — Cyber assets essential to the reliable operation of critical assets.

RTBPTF introduces the following terms:

- Critical Equipment — Installed equipment that makes up the communication networks, data links, and computer equipment that are directly used as the computer infrastructure for critical real-time tools (see definition below). Critical equipment is essential for reliability entities to ensure the reliable operation of the bulk electric system. Critical equipment is a subset of critical cyber assets (i.e., not all critical cyber assets are considered critical equipment; critical equipment is critical cyber assets that are directly used as the computer infrastructure for critical real-time tools).
- Critical Real-Time Tool — Installed software that is essential (and mandatory) to support, operate, or otherwise interact with bulk electric system operations. Critical real-time tools do not include process control applications or distributed control system applications installed in generating stations, switching stations, or substations.

Significance to the August 14, 2003 Blackout

The support and maintenance tools discussed in this report address some of the issues identified by the August 14, 2003 blackout investigation. Change management tools, facilities monitoring applications, and critical applications monitoring tools enhance operator and support personnel situational awareness. Many of the recommendations for adding new requirements to the existing NERC reliability standards that are presented in the following sections of Chapter 5 relate to these three support and maintenance tools/applications.

The display maintenance tool does not directly support situational awareness; however, it is essential to the creation of power system displays, which are used by operators to enhance their situational awareness. The trouble reporting tool can be used as part of a change management tool to track and document application, system, and display problems and the resolution of each problem. Improper use of each of these tools was cited as a contributing factor to the August 14, 2003 blackout.

Processes for Interactions between Support Personnel and Operators

The lack of situational awareness caused by the failure of support personnel to have or use proper change management tools and practices played a role in the August 14, 2003 blackout. Two failures of this type were identified.

The first failure is identified in a report by the NERC Steering Group (2004):

> FE control center computer support staff did not fully test the functionality of applications, including the alarm processor, after a server failover and restore. After the FE computer support staff conducted a warm reboot of the energy management system to get the failed servers operating again, they did not conduct a sufficiently rigorous test of critical energy management system applications to determine that the alarm processor failure still existed. Full testing of all critical energy management functions after restoring the servers would have detected the alarm processor failure as early as 15:08 and would have cued the FE system operators to use an alternate means to monitor system conditions. Knowledge that the alarm processor was still failed after the server was restored would have enabled FE operators to proactively monitor system conditions, become aware of the line outages occurring on the system, and act on operational information that was received. Knowledge of the alarm processor failure would also have allowed FE operators to warn MISO and neighboring systems, assuming there was a procedure to do so, of the loss of a critical monitoring function in the FE control center computers, putting them on alert to more closely monitor conditions on the FE system.[2]

Because of this deficiency, NERC directed FE to "develop and implement a written procedure describing the interactions between control center technical support personnel and system operators. The procedure shall address notification of loss of critical functionality and testing procedures.[3]" Change management tools and practices would have aided FE in managing this type of support and maintenance issue with its critical reliability tools. A "sufficiently rigorous test" for critical equipment and critical reliability tools is necessary when changes/modifications occur to ascertain the integrity of critical infrastructure and the tools and applications used to maintain the reliability of the bulk electric system.

The second failure was when MISO support personnel analyzed the unacceptably large mismatch produced by its state estimator. The NERC Steering Group report (2004)

---

[2] Technical Analysis of the August 14, 2003, Blackout: *What Happened, Why, and What Did We Learn?* 2004. Report to the NERC Board of Trustees by the NERC Steering Group. July 13. p. 96.
[3] Ibid., p. 118.

states, "... the first sign of trouble came at 12:15, when MISO's state estimator experienced an unacceptably large mismatch error between state-estimated values and measured values. The error was traced to an outage of Cinergy's Bloomington-Denois Creek 230-kV line that was not updated in MISO's state estimator. The line status was quickly corrected, but the MISO analyst forgot to reset the state estimator to run automatically every five minutes.[4]" Without proper change management tools and practices, an error such as this failure to reset a critical real-time tool and verify the integrity of the tool with operators, is more likely to occur. Errors of this type can compromise bulk electric system reliability.

As a result of the above deficiency, NERC directed MISO to "reevaluate and improve its communications protocols and procedures with operational support personnel within MISO…[5]" Change management tools and practices would have aided MISO in managing this type of support and maintenance issue with at least one of its critical reliability tools.

Section 5.1 discusses change management tools and practices, and Section 5.5 discusses trouble reporting tools, which can also be viewed as change management tools. The relationship between the two sections is the strong methodology for tying support personnel actions related to critical equipment and critical real-time tools to operator situational awareness; that is, both tools provide a means to communicate to operators any changes made to critical equipment and critical real-time tools, which enhances situational awareness.

Critical Equipment and Critical Real-Time Tools Monitoring

The ability to maintain operator situational awareness of the status of critical equipment and critical real-time tools is an essential component of reliability. NERC Steering Group analysis of the 2003 blackout (2004) states:

> …shortly after 14:14, the alarm and logging system in the FE control room failed and was not restored until after the blackout. Loss of this critical control center function was a key factor in the loss of situational awareness of system conditions by the FE operators. Unknown to the operators, the alarm application failure eventually spread to a failure of multiple energy management system servers and remote consoles, substantially degrading the capability of the operators to effectively monitor and control the FE system...[6]

The document further states that:

> … at 14:41, the primary server hosting the [FE] EMS alarm processing application failed, due either to the stalling of the alarm application, the "queuing" to the remote terminals, or some combination of the two. Following pre-programmed instructions, the alarm system application and all other EMS

---

[4] Technical Analysis of the August 14, 2003, Blackout: *What Happened, Why, and What Did We Learn?* 2004. Report to the NERC Board of Trustees by the NERC Steering Group. July 13. p. 28.
[5] Ibid, p. 118.
[6] Ibid, p. 27.

> software running on the first server automatically transferred ("failed-over") onto the back-up server. However, because the alarm application moved intact onto the back-up while still stalled and ineffective, the back-up server failed 13 minutes later, at 14:54. Accordingly, all of the EMS applications on these two servers stopped running… The concurrent loss of two EMS servers apparently caused several new problems for the FE EMS and the system operators using it… although the FE computer support staff should have been aware that concurrent loss of its servers would mean the loss of alarm processing on the EMS, the investigation team has found no indication that the IT staff informed the control room staff either when they began work on the servers at 14:54 or when they completed the primary server restart at 15:08. At 15:42, a member of the computer support staff was told of the alarm problem by a control room operator. FE has stated to investigators that their computer support staff had been unaware before then that the alarm processing sub-system of the EMS was not working.[7]

The above excerpts illustrate the importance of operator and support personnel awareness of the availability status of critical equipment and critical real-time tools. Unavailability of critical equipment and critical real-time tools compromises the reliability of the bulk electric system. In addition, unavailability of critical equipment and critical real-time tools hinders operators' ability to maintain situational awareness.

RTBPTF Recommendations for New Reliability Standards

The NERC Cyber Security Standards address many of the issues related to critical cyber asset security that were identified by the August 14, 2003 blackout investigation. The Cyber Security Standards require that tools and processes be established to ensure that at least minimum security controls are in place to protect critical equipment. However, RTBPTF believes that the Cyber Security Standards do not sufficiently ensure operator situational awareness (i.e., RTBPTF believes that operators must be required to know the availability status of critical equipment and critical real-time tools because these tools are essential to the reliable operation of the bulk electric system).

In the sections that follow, RTBPTF makes several recommendations for modifying the requirements of NERC standard IRO-005. RTBPTF also recommends the development of three operating guidelines and identifies one area requiring additional analysis to support the recommended changes to IRO-005. In addition, the task force identifies eight entities whose use of support and maintenance tools can be considered examples of excellence within the industry.

Specifically, RTBPTF recommends that:

- Each RC and TOP be required to identify critical equipment (in a Critical Equipment Identification Document) that it uses to monitor the bulk electric system and maintain awareness of critical equipment status to ensure that

---

[7] Page 33-34 of the "Technical Analysis of the August 14, 2003, Blackout: What Happened, Why, and What Did We Learn?" document

unavailability of critical equipment does not impair the reliable operation of the bulk electric system.

- Each RC and TOP be required to include, at a minimum,
    - The following list of critical real-time tools used in the operation and monitoring of the bulk electric system: alarm tools, telemetry data systems (including applications for SCADA and ICCP Data Link telemetry data), state estimator, network topology processor, and contingency analysis.
    - The following list of critical equipment used in the operation and monitoring of the bulk electric system: servers or computers that contain the critical real-time tools specified above and the data links that provide the input to the critical real-time tools specified above.
- Each RC and TOP be required to maintain a Critical Equipment Monitoring Document identifying its tools and procedures for monitoring critical equipment (including critical real-time applications) and notifying operators when critical equipment is unavailable.
- Each RC and TOP be required to implement automated tools or organizational processes to monitor critical equipment (which includes critical real-time applications) and related system events to ensure reliable operation of the bulk electric system.
- Each RC and TOP be required to maintain event logs pertaining to critical equipment (which includes critical real-time applications) status for a period of one year.
- Each RC and TOP be required to maintain a Critical Equipment Maintenance and Testing Document identifying its tools and procedures for maintenance, modification, and testing of critical equipment.

RTBPTF also proposes measures for the requirements recommended for Standard IRO-005-1.

Section 5.1
Display Maintenance Tool

Definition

Support personnel use the display maintenance tool to develop and maintain visual interfaces that operators use to maintain situational awareness, i.e., to monitor and assess bulk electric system reliability and/or take action to maintain system reliability.

Background

Displays are human-machine interface (HMI) views that allow operators to monitor, assess, or perform necessary actions to maintain the reliability of the bulk electric system during normal and emergency operations. Displays usually present visual representations of power system elements and other application data; this information is the basis for operator situational awareness. Although not a real-time tool, the display maintenance tool is critical for support personnel to keep visual interfaces operational.

Summary of Findings

The majority (96 percent) of respondents to the display maintenance tool section of the Real-Time Tools Survey have an operational display maintenance tool that offers the functionality defined in the survey. The overwhelming majority (94 percent) of all respondents that have an operational display maintenance tool rated it “essential” for situational awareness. Not one entity rated the application as of “minimal” or of “no value.” One respondent notes that “without a display maintenance tool, there would be no way to build supporting displays.” Table 5.1-1 shows the breakdown of the ratings.

NOTE: In the columns of all tables in this section that list percentages of respondents, the percentage value is preceded by the number of respondents out of the total that gave the indicated response. For example, “32/38=84%” means that 32 out of a total of 38 respondents, or 84% of respondents, gave the indicated response.

Respondent Type	How do you Rate the Value of Your Display Maintenance Tool as a Critical Support Tool to Enhance Reliability Operation and Situational Awareness?	
	“Essential”	“Desirable”
All	29/31=94%	2/31=6%
RC	13/13=100%	0/0=0%
Others	16/18=89%	2/18=11%

Table 5.1-1 — Value of Display Maintenance Tool

Although respondents consistently rate the application as an essential support tool, they report significant variation in its implementation and usage.

Power System Displays

Most power system displays built for operators present SCADA measurements/telemetry data from the field. Most respondents indicate that they use power system displays that contain the state estimator or operator power-flow application solution (see Table 5.1-2). This is common industry practice: to leverage display of SCADA measurements to represent equivalent state estimator or operator power-flow solutions. Some entities use the same power system representation for their DTS application as well as their outage scheduler application. The most widely used types of power system displays are:

- One-Line Displays — visually represent a substation (transmission or distribution) and its corresponding power system elements. Discussed extensively in Section 2.2, Visualization Techniques.
- Transmission-Line Circuit Displays — visually represent the circuit connectivity of transmission substations to adjacent transmission substations; the distribution substations between two transmission substations are also often represented.
- Transmission Overview Displays — show a wide-area view of a transmission grid. Could also be referred to as dynamic overview displays or wide-area visualization displays (depending on usage). Discussed extensively in Section 2.2, Visualization Techniques.

One-Line Displays			
Type	**All**	**RC**	**Others**
SCADA	31//31=100%	12/12=100%	19/19=100%
State Estimator	27/31=87%	12/12=100%	15/19=79%
Power Flow	27/31=87%	12/12=100%	15/19=79%
DTS	17/31=55%	8/12=67%	9/19=47%
Outage Scheduler	3/31=10%	1/12=8%	2/19=10%
Transmission-Line Circuit Displays			
Type	**All**	**RC**	**Others**
SCADA	25/29=86%	10/12=83%	15/19=79%
State Estimator	26/29=90%	11/12=92%	15/19=79%
Power Flow	25/29=86%	10/12=83%	15/19=79%
DTS	14/29=48%	7/12=58%	7/19=37%
Outage Scheduler	3/29=10%	1/12=8%	2/19=10%
Transmission Overview Displays			
Type	**All**	**RC**	**Others**
SCADA	28/31=90%	11/12=92%	17/19=89%
State Estimator	22/31=71%	9/12=75%	13/19=68%
Power Flow	21/31=68%	9/12=75%	12/19=63%
DTS	14/31=45%	6/12=50%	8/19=42%
Outage Scheduler	2/31=6%	1/12=8%	1/19=5%

Table 5.1-2 — Power System Displays

Display Validation

Power system displays are critical visual representations of the monitored electric system, so the accuracy of display information is of great importance. The Real-Time Tools Survey asked respondents for a free-form description of the methods used to validate their displays. Respondents described the following methods:

- Display Testing — Displays are tested initially from a development system before being loaded into the operational system. Validation includes error checking and functional testing to ensure that displays will not harm the operational system. Links between displays and operational data are checked to be sure they are accurate and working correctly.
- Data Accuracy Checks — Despite a wide range of tools available for checking display problems, display accuracy is commonly checked manually by comparison to paper diagrams.

Noteworthy Functional Features

The survey results reveal that display maintenance tools are widely used and considered essential. The survey did not quantify their effectiveness; however, it is clear that accurate displays and detection of display errors enhance situational awareness. Many entities use multiple tools and practices to support display maintenance for various applications and systems, including wide-area overview displays and mapboards. RTBPTF believes these findings could help entities improve and benchmark their current display maintenance processes through self assessment. The following is a list of functional features deemed “essential” (based on ratings by a significant majority of survey respondents) to enhance situational awareness:

- Automatic Display Generator for Power System Displays — Enable an application to automatically generate power system displays from a single display. For example, from a SCADA station one-line display, the state estimator, power flow, etc. station one-line displays can be generated. Without this feature, support personnel would have to manually create the other power system displays. Manually creating displays could introduce errors and inconsistency; creating similar displays using a program could mitigate this problem. Forty-nine percent of respondents have an operational version of this feature. Of the entities that have this operational feature, 71 percent rate it “essential,” 14 percent as “desirable,” and 14 percent as of “minimal value” for situational awareness.
- Bad Display Link Indicator — Allows an application to automatically generate a summary of incorrect display linkages for telemetered data for multiple displays that use a given link. This feature signifies that the data being presented may be inaccurate. Forty-one percent of survey respondents have an operational version of this feature. Of the entities that have this feature operational, 92 percent rate it as “essential,” and 8 percent rate it as “desirable” for situational awareness.

Recommendations for New Reliability Standards

RCs, TOPs, and BAs depend on the availability and accuracy of displays to operate the bulk electric system in a coordinated manner so that it performs reliably under normal and abnormal conditions, as defined in NERC standards. The Real-Time Tools Survey responses reveal significant variation in display maintenance practices; the industry as a whole has no cohesive method of maintaining displays for operator use. The display maintenance tool indirectly affects bulk electric system reliability, but the availability and accuracy of the displays designed and created using this tool directly affects system reliability. These displays are discussed in Section 2.2, Visualization Techniques. RTBPTF has no recommendations for new reliability standards for the display maintenance tool.

Recommendations for Operating Guidelines

Because RTBPTF recommends no reliability standards related to display maintenance tools, it also has no recommendations for operating guidelines.

Areas Requiring More Analysis

RTBPTF identified no areas requiring additional analysis for display maintenance tools.

Examples of Excellence

RTBPTF cites the California Mexico RC's use of a display maintenance tool application to ensure that its energy management system displays are functioning properly as an example of excellence (See EOE-17 in Appendix E).

Section 5.2
Change Management Tools and Practices

Definition

Support personnel use change management tools and practices to maintain, modify, and/or test critical equipment[8] that operators use to monitor and perform necessary actions to maintain reliability of the bulk electric system.

Background

The availability and integrity of critical equipment in control centers directly affect reliability. Therefore, the tools and practices used to maintain, modify, and test critical equipment — usually called change management tools and practices – are directly related to reliability. Support personnel must use proper change management tools and practices to avoid disruptions in the function or availability of critical equipment that could affect operators' situational awareness.

The *Outage Task Force Final Blackout Report* notes that, as part of the events related to the August 2003 blackout, FE support personnel rebooted servers that had a failed alarm module without checking with control room staff/operators to confirm that all applications were running properly. In another event related to the blackout, MISO support personnel left software in a manual operation mode after solving a state estimator mismatch. These two examples signify a deficiency in change management tools and practices. On each occasion, the problem could have been averted if proper maintenance and testing procedures had been in place. In FE's case, effective change management tools and practices would have required that personnel check with the operators to find out whether the alarm tools application problem was resolved after the module reboot. In MISO's case, effective change management tools and practices would have required verification that the state estimator was running in a condition that allowed the operator to use it, so the application would not have been left in manual mode.

In short, failure of support personnel to use appropriate change management tools and practices played a role in the August 14, 2003 blackout. Causal analysis in the *Outage Task Force Final Blackout Report* reveals the following deficiencies:

> Cause 1c: FirstEnergy control center computer support staff did not fully test the functionality of applications, including the alarm processor, after a server failover and restore.

---

[8] For the purposes of this discussion, *critical equipment* is defined as installed equipment that makes up infrastructure and systems (including communication networks, data links, hardware, software applications, and data bases) that are directly used as critical real-time tools. Critical equipment is a subset of critical cyber assets. *Critical real-time tools* are defined as installed software that is essential to support, operate, or otherwise interact with bulk electric system operations. All reliability entities (not just RCs) need critical equipment and real-time tools to ensure reliable operation of the bulk electric system.

The Corrective Actions section of the *Outage Task Force Final Blackout Report* recommends:

g. Technical Support. FirstEnergy shall develop and implement a written procedure describing the interactions between control center technical support personnel and system operators. The procedure shall address notification of testing procedures and loss of critical functionality.[9]

Summary of Findings

The Real-time Tools Best Practices Survey was designed to examine current tools and practices in software (rather than hardware) maintenance, modification, and testing. Most survey respondents (78 percent) have operational software maintenance tools. They also indicate that they have maintenance, modification, and testing practices. The majority (77 percent) of all respondents that have operational software maintenance tools rate these tools as "essential" for situational awareness; a minority (23 percent) rate their tools "desirable" for situational awareness. Not one entity rates its tools as of "minimal value" or "no value" for situational awareness. One respondent states that "it is essential for support personnel to have a quick method to access the source code of critical/core applications in case there is an issue that requires code repairs. This access needs to be controlled so that the operational environment is not affected when code is compiled and loaded into the operational system." This majority percentage was consistent across all entity types except BAs (see Table 5.2-1).

Entity Type	How do You Rate the Value of Your Software Maintenance Tools and Practices as a Critical Support Tool to Enhance Reliability Operation and Situational Awareness?	
	"Essential"	"Desirable"
All	27/35=77%	8/35=23%
RCs	12/16=77%	4/16=23%
Others	15/19=79%	4/19=21%

Table 5.2-1 — Value of Software Maintenance Tools

The survey results also reveal that most entities (97 percent) that have operational software maintenance tools also have source codes on hand for their reliability tools/applications. Most entities (91 percent) indicate that their support staff can modify (when necessary) the source codes of their reliability tools/applications.

[9] U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April.

Practices/Processes Related to Software Maintenance Tools

Most entities (85 percent) that have operational software maintenance tools have some form of code control process, i.e., a software (source code) change management process, such as version control, change tracking, or user management and administration. The majority of entities (81 percent) that have this process/tool available rate it "essential" for enhancing situational awareness.

Most entities (76 percent) that have operational software maintenance tools do not have the ability to notify (via paging) software support personnel if new software is loaded on-line. This question was included in the survey because RTBPTF believes this type of notification enhances situational awareness of support personnel when certain applications are being updated online.

Recommendations for New Reliability Standards

To ensure proper maintenance, modification, and testing, RTBPTF recommends that new requirements for change management tools and practices be added to existing standard IRO-005 (Reliability Coordination – Current Day Operations) to strengthen operator situational awareness. RTBPTF recommends adding the change management requirements to the reliability coordination current day operations standard rather than the cyber security standards because the latter focus primarily on protecting and securing critical cyber assets; specifically, Standard CIP-003 requires that responsible entities have minimum security management controls in place to protect critical cyber assets. The cyber security standards do not, however, explicitly address operator situational awareness of critical equipment that may affect the reliable operation of the bulk electric system.

Change management requirements could, in principle, also be added to NERC's cyber security standards CIP-002 through CIP-009, which specifically address change control and configuration management for software and hardware maintenance. Standard CIP-003 (Cyber Security – Security Management Controls), Requirement 6, states that "the Responsible Entity shall establish and document a process of change control and configuration management for adding, modifying, replacing, or removing Critical Cyber Asset hardware or software, and implement supporting configuration management activities to identify, control, and document all entity or vendor-related changes to hardware and software components of Critical Cyber Assets pursuant to the change control process." The cyber security standards require that tools and processes be established so that minimum security controls are in place to protect critical equipment.

However, RTBPTF recommends adding the change management requirements to Standard IRO-005 because operator awareness of the status of critical equipment (which is directly related to critical equipment maintenance, modification, and testing processes) is essential to the RC's continuous awareness of conditions that may impair the operator's ability to operate the bulk electric system reliably. RTBPTF recommends that a new requirement be added to IRO-005 to require RCs and TOPs to implement automated tools or organizational processes to monitor critical equipment availability, including the activities related to critical equipment maintenance, modification, and testing.

RTBPTF Recommendation

The requirements recommended for addition to existing Standard IRO-005 are stated below.[10] The full text of interrelated requirements applicable to critical equipment, which comprises three areas, (change management tools and practices, facilities monitoring (Section 5.3), and critical applications monitoring (Section 5.4)) is presented here for clarity. The requirements related to the topic of this section of the report, change management tools and practices, are highlighted in italic font.

PR1. Each reliability coordinator and transmission operator shall monitor and maintain awareness of critical equipment status to ensure that the unavailability of critical equipment does not impair the reliable operation of the bulk electric system. Other entities supporting or complementing the reliability coordinator's or transmission operator's ability to operate the bulk electric system reliably shall be subject to the same requirements as the reliability coordinator or transmission operator respectively.

PR1.1. Identification of critical equipment — Each reliability coordinator and transmission operator shall identify the critical equipment it uses for bulk electric system operation and monitoring. This includes the critical equipment of parties to whom the reliability coordinator or transmission operator has delegated reliability functions. Each reliability coordinator and transmission operator shall maintain a Critical Equipment Identification Document that lists all critical equipment. The Critical Equipment Identification Document shall be kept current at all times.

PR1.1.1. Each reliability coordinator and transmission operator shall include, at a minimum, the following list of critical real-time tools used in the operation and monitoring of the bulk electric system: alarm tools, telemetry data systems (includes applications for SCADA and ICCP Data Link telemetry data), state estimator, network topology processor, and contingency analysis.

PR1.1.2. Each reliability coordinator and transmission operator shall include, at a minimum, the following list of critical equipment used in the operation and monitoring of the bulk electric system: servers or computers that contain the critical real-time tools specified above and the data links that provide the input to the critical real-time tools specified above.

---

[10] Proposed requirements are designated "PR," and proposed measures are designated "PM."

Recommendation – S37

Maintain a Critical Equipment Monitoring Document to identify tools and procedures for monitoring critical equipment.

PR1.2. *Monitoring of Critical Equipment — Each reliability coordinator and transmission operator shall maintain a Critical Equipment Monitoring Document identifying its tools and procedures for monitoring critical equipment (which includes critical real-time applications). This document shall describe how to verify that the tools and procedures are functioning and being used as intended. This document shall describe the tools and procedures for operator notification when critical equipment is unavailable*.

PR1.2.1. *Each reliability coordinator and transmission operator shall implement automated tools or organizational processes to monitor critical equipment (which includes critical real-time applications) and related system events to ensure reliable operation of the bulk electric system. These tools or organizational processes shall be described in the Critical Equipment Monitoring Document.*

Recommendation – S38

Maintain event logs pertaining to critical equipment status for a period of one year.

PR1.3. *Each reliability coordinator and transmission operator shall maintain event logs pertaining to critical equipment (which includes critical real-time applications) status for a period of one year. At a minimum, the event logs shall contain the following information regarding any event that affects the functionality and/or availability of critical equipment. The event log shall address the following questions: What happened? When did it happen? Who was notified? What was the resolution?*

Recommendation – S39

Maintain a Critical Equipment Maintenance and Testing Document identifying tools and procedures for maintenance, modification, and testing of critical equipment.

PR1.4. *Maintenance of Critical Equipment — Each reliability coordinator and transmission operator shall maintain a Critical Equipment Maintenance and Testing Document identifying its tools and procedures for maintenance, modification, and testing of critical equipment. This document shall describe how to verify that the tools and procedures are functioning and being used as intended*.

RTBPTF recommends the following measures for the requirements stated above. The measures related to change management tools and practices are written in italic font.

PM 1. Measures for Critical Equipment Monitoring

PM 1.1 The Critical Equipment Identification Document must be available as specified in Requirement PR1.1. Additionally, each reliability coordinator and transmission operator shall demonstrate that the Critical Equipment Identification Document is kept current at all times.

PM 1.1.1. As specified in Requirement PR1.1.1, the Critical Equipment Identification Document must contain, as part of its list of critical real-time applications, the following applications: alarm tools, telemetry data systems (includes applications for SCADA and ICCP Data Link telemetry data), state estimator, network topology processor, and contingency analysis.

PM 1.1.2. As specified in Requirement PR1.1.2, the Critical Equipment Identification Document must contain, as part of its list of critical equipment, the following equipment: servers or computers that contain the critical real-time tools, and the data links that provide the input to the critical real-time tools specified.

PM 1.2 *The Critical Equipment Monitoring Document must be available as specified in PR1.2. Additionally, each reliability coordinator and transmission operator must demonstrate that the Critical Equipment Monitoring Document is kept current at all times and that the documented tools/procedures are used as intended*.

PM 1.2.1. *Each reliability coordinator and transmission operator must demonstrate, upon request, its capability to monitor critical equipment via automated tools (e.g., critical equipment status displays or visualization tools) or organizational processes (e.g., trouble* *notification processes) as stated in Requirement PR1.2.1.*

PM 1.3 *Each reliability coordinator and transmission operator must demonstrate that the event logs as stated in Requirement PR1.3 contain the required information*.

PM 1.4 *The Critical Equipment Maintenance and Testing Document must be available as specified in PR1.4.*

Rationale

The "Purpose" section of Standard IRO-005 states, "The Reliability Coordinator must be continuously aware of conditions within its Reliability Coordinator Area and include this information in its reliability assessments. The Reliability Coordinator must monitor Bulk Electric System parameters that may have significant impacts upon the Reliability Coordinator Area and neighboring Reliability Coordinator Areas." RTBPTF believes that operator awareness of the status of critical equipment (which is directly related to critical equipment maintenance, modification, and testing processes) is essential to the reliability coordinator's continuous awareness of conditions that may impair the operator's ability to operate the bulk electric system reliably. Therefore, the change management requirements for critical equipment maintenance, modification, and testing should be included as part of this standard. Other entities supporting or complementing the RC's ability to operate the bulk electric system reliably must be subject to the same requirements as the RC. As noted in the Summary of Findings section above, the *Outage Task Force Final Blackout Report* notes that the lack of strong change management tools and practices contributed to the lack of operator situational awareness related to the August 2003 blackout*.*

RTBPTF includes TOPs in the recommendations stated above because these entities are subject to the Reliability Toolbox requirement.[11]

Recommendations for Operating Guidelines

RTBPTF recommends development of the following operating guidelines for change management tools and practices. These operating guidelines support the recommended additional requirements to Standard IRO-005-1 stated above.

- Each reliability coordinator should have a demonstrated change management process for performing critical equipment maintenance, modification, and testing. This change management process should have the objective/purpose of ensuring the availability and integrity of critical equipment. The change management process should, at a minimum, include the following:
    - Management, operator, and support personnel notification and approval for production system changes
    - Pre- and post-production testing of system installation testing

[11] See the Reliability Tool Box Rationale and Recommendation section as well as the specific recommendations for each tool in the Reliability Toolbox.

- Personnel authorization and security
- System source code backup and recovery

- Each reliability coordinator should have a change management tool that has, at a minimum, the following capabilities:
  - Audit logging of all activities (modifications, additions, deletions, etc.) related to all source code files
  - Version control with the ability to roll back to an earlier version

Areas Requiring More Analysis

RTBPTF identified no areas requiring additional analysis for change management tools and practices.

Examples of Excellence

RTBPTF cites PJM's use of a feature management system that provides audit logging and version control capabilities as an example of excellence (See EOE-18 in Appendix E). The approach taken by PJM ensures that software modifications do not compromise the availability and integrity of their critical real-time applications that support operator situational awareness

Section 5.3
Facilities Monitoring

Definition

The facilities monitoring application tracks the status of computer systems equipment, servers, backup systems, communications systems, networks and other critical facilities. This tool allows operators and/or support personnel to be aware of critical equipment issues that may affect the availability of critical real-time tools used to operate and monitor the bulk electric system.

Background

As discussed in detail in Section 5.0, Support and Maintenance Tools, situational awareness of the status of critical equipment, which includes facilities such as computer systems equipment, servers, backup systems, communications systems, networks and other critical facilities in the control center, is an essential component directly related to reliability. The *Outage Task Force Final Blackout Report* states that FE's operators were unaware of the failure and the concurrent loss of two EMS servers that apparently caused several new problems for the FE EMS and the operators using it. This illustrates the importance of having monitoring tools that report unavailability of critical equipment. Operators need to be aware when their ability to monitor the bulk electric system is compromised. Proper notification of maintenance and support personnel is requisite for real-time operations.

The operator has to have keen awareness of the status and availability of critical equipment. This includes critical equipment that is used as a backup to primary critical equipment. The operator could have no provision for monitoring the bulk electric system if a critical piece of equipment is unavailable or not working correctly. Critical real-time tools depend on critical equipment, and a facilities monitoring application allows for operators to be aware of the status and availability of critical equipment, which enhances operator situational awareness.

Summary of Findings

The majority of respondents (86 percent) have an operational facility monitoring application that offers the same functionality as defined in the Real-Time Tools Survey. Interestingly, all RCs report having an operational facilities monitoring application. For respondents that have an operational facilities monitor, the majority (84 percent) rate this application "essential" for situational awareness while 16 percent rate it "desirable." Not one entity rates the application as of "minimal value" or "no value" for situational awareness. One of the respondents states that "any information as to the 'state of the operational system' is a key indicator for situational awareness. For system support personnel, maintaining situational awareness of key infrastructure equipment is analogous to maintaining situational awareness of bulk power system elements." Table 5.3-1 summarizes the survey results.

Entity Type	How do You Rate the Value of Your EMS Facilities Monitor as a Critical Support Tool to Enhance Reliability Operation and Situational Awareness?	
	"Essential"	**"Desirable"**
All	32/38=84%	6/38=16%
RC	13/15=84%	2/15=16%
Others	19/23=83%	4/23=17%

Table 5.3-1 — Value of Facilities Monitor Application

These data suggest that the majority of respondents consider the facilities monitor an essential operational support tool. Because the survey results reveal a significant variation in practice, implementation, and use of this application, it is a logical candidate for some degree of standardization.

The survey asked respondents to identify the types of equipment/facilities that are monitored. A majority of respondents monitor the status of their critical servers, voice/data communication links, internal networks, and backup facilities listed (see Table 5.3-2).

Equipment	All	RC	Others
Status of Critical Servers	38/38=100%	15/15=100%	23/23=100%
Mapboard (Hardware Status) Availability	20/38=53%	11/15=73%	9/23=39%
Voice/Data Communication Links	33/38=87%	13/15=87%	20/23=87%
Internal Communication Network(s)	29/38=76%	12/15=80%	17/23=74%
RTU Status	20/38=79%	11/15=73%	9/23=39%
Availability of Backup System	33/38=87%	13/15=87%	20/23=87%
Power Supply (UPS)	26/38=68%	13/15=87%	13/23=56%
Power Supply (Backup Generators)	24/38=63%	12/15=80%	12/23=52%
Batteries	20/38=53%	10/15=67%	10/23=43%
Heating, ventilation, and air conditioning	15/38=39%	7/15=47%	8/23=35%
Fire Protection Systems	15/38=39%	7/15=47%	8/23=35%

Table 5.3-2 — Equipment/facilities Monitored Using Facilities Monitoring Application, by Entity Type

The survey reveals that entities monitor equipment that is essential to the continuing operation of their control centers. This encouraging result shows that monitoring of critical equipment is a prevailing industry practice. Awareness of critical equipment status supports situational awareness. Critical equipment monitoring tells operators what equipment is available or unavailable, which allows operators to determine whether the capability of these tools is degraded by critical equipment problems.

The survey also examined the functional features of facilities monitoring applications. Ninety-seven percent of respondents report that their facilities monitors interface directly with their alarm tools applications and can generate critical equipment status alarms. Of the entities that use this feature, 86 percent rated it “essential” for situational awareness. These data suggest that an interface between the facilities monitor and the alarm tools enhances situational awareness.

Operators at most entities (87 percent) have access to a visual representation of critical equipment status. Seventy-three percent of entities that have this feature rate it "essential" for situational awareness, 24 percent rate this feature "desirable," and 3 percent rate it as having "minimal value." These data suggest that a visual representation of critical equipment status enhances operator situational awareness.

Many entities (56 percent) have a system that pages support personnel when the facilities monitor indicates that a critical equipment status is unavailable. Fifty-five percent of entities that have this functional feature rate it "essential" for situational awareness, 40 percent rate it as "desirable," and 5 percent rate it as having "minimal value." These data suggest that an interface between the facilities monitor and a paging system enhances operator situational awareness.

Insufficient data were collected to properly evaluate the usage and implementation of the respondents' facilities monitor applications. Ideally, to ascertain critical equipment status, the application should be independent of the equipment being monitored. Further exploration is needed to determine whether this strategy is used in the industry. More data are also needed on the methodology used to declare critical equipment "unavailable."

Recommendations for New Reliability Standards

Because continual monitoring of the availability of critical equipment/critical real-time tools is essential for reliable power system operation, as indicated by the survey results, RTBPTF recommends adding new facilities monitoring requirements to existing standard IRO-005 (Reliability Coordination – Current Day Operations), to strengthen operator situational awareness.

Facilities monitoring requirements could, in principle, also be added to NERC's cyber security standards CIP-002 through CIP-009, which address securing of critical cyber assets and require that tools and processes be established so that minimum security controls are in place to protect critical equipment. Specifically, Standard CIP-007, Requirement 6 mandates that the responsible entity ensure that all cyber assets within the electronic security perimeter, to the degree technically feasible, implement automated tools or organizational process controls to monitor system events related to cyber security. However, Standard CIP-007 does not explicitly address operator situational awareness of critical equipment that may affect the reliable operation of the bulk electric system; rather it focuses on automated tools or organizational process controls to monitor system events related to cyber security only. Therefore, the RTBPTF recommends adding the facilities monitoring requirements to Standard IRO-005. This standard is a more appropriate location for the requirements because the purpose of IRO-005 is operator awareness of bulk electric system parameters.

RTBPTF Recommendation

The requirements recommended for addition to existing Standard IRO-005 are stated below. The full text of interrelated requirements applicable to critical equipment, which comprises three areas, (change management tools and practices (Section 5.2), facilities monitoring, and critical applications monitoring (Section 5.4)) is presented here for clarity. The requirements related to the topic of this section of the report, facilities monitoring, are highlighted in italic font.

Recommendation – S40

Monitor and maintain awareness of critical equipment status to ensure that lack of availability of critical equipment does not impair reliable operation.

PR1. *Each reliability coordinator and transmission operator shall monitor and maintain awareness of critical equipment status to ensure that the unavailability of critical equipment does not impair the reliable operation of the bulk electric system. Other entities supporting or complementing the reliability coordinator's or transmission operator's ability to operate the bulk electric system reliably shall be subject to the same requirements as the reliability coordinator or transmission operator respectively.*

PR1.1. *Identification of critical equipment — Each reliability coordinator and transmission operator shall identify the critical equipment it uses for bulk electric system operation and monitoring. This includes the critical equipment of parties to whom the reliability coordinator or transmission operator has delegated reliability functions. Each reliability coordinator and transmission operator shall maintain a Critical Equipment Identification Document that lists all critical equipment. The Critical Equipment Identification Document shall be kept current at all times.*

PR1.1.1. Each reliability coordinator and transmission operator shall include, at a minimum, the following list of critical real-time tools used in the operation and monitoring of the bulk electric system: alarm tools, telemetry data systems (includes applications for SCADA and ICCP Data Link telemetry data), state estimator, network topology processor, and contingency analysis.

PR1.1.2. *Each reliability coordinator and transmission operator shall include, at a minimum, the following list of critical equipment used in the operation and monitoring of the bulk electric system: servers or computers that contain the critical real-time tools specified above and* *the data links that provide the input to the critical real-time tools specified above.*

PR1.2. *Monitoring of Critical Equipment — Each reliability coordinator and transmission operator shall maintain a Critical Equipment Monitoring Document identifying its tools and procedures for monitoring critical equipment (which includes critical real-time applications). This document shall describe how to verify that the tools and procedures are functioning and being used as intended. This document shall describe the tools and procedures for operator notification when critical equipment is unavailable.*

PR1.2.1. Each reliability coordinator and transmission operator shall implement automated tools or organizational processes to monitor critical equipment (which includes critical real-time applications) and related system events to ensure reliable operation of the bulk electric system. These tools or organizational processes shall be described in the Critical Equipment Monitoring Document.

PR1.3. Each reliability coordinator and transmission operator shall maintain event logs pertaining to critical equipment (which includes critical real-time applications) status for a period of one year. At a minimum, the event logs shall contain the following information regarding any event that affects the functionality and/or availability of critical equipment. The event log shall address the following questions: What happened? When did it happen? Who was notified? What was the resolution?

PR1.4. Maintenance of Critical Equipment — Each reliability coordinator and transmission operator shall maintain a Critical Equipment Maintenance and Testing Document identifying its tools and procedures for maintenance, modification, and testing of critical equipment. This document shall describe how to verify that the tools and procedures are functioning and being used as intended.

RTBPTF recommends the following measures for the requirements stated above. The measures related to change management tools and practices are written in italic font.

PM 1. *Measures for Critical Equipment Monitoring*

PM 1.1 *The Critical Equipment Identification Document must be available as specified in Requirement PR1.1. Additionally, each reliability coordinator and transmission operator shall demonstrate that the Critical Equipment Identification Document is kept current at all times.*

PM1.1.1. As specified in Requirement PR1.1.1, the Critical Equipment Identification Document must contain, as part of its list of critical real-time applications, the following applications: alarm tools, telemetry data systems (includes applications for SCADA and ICCP Data Link telemetry data), state estimator, network topology processor, and contingency analysis.

PM1.1.2. *As specified in Requirement PR1.1.2, the Critical Equipment Identification Document must contain, as part of its list of critical equipment, the following equipment: servers or computers that contain the critical real-time tools, and the data links that provide the input to the critical real-time tools specified.*

PM 1.2 *The Critical Equipment Monitoring Document must be available as specified in PR1.2. Additionally, each reliability coordinator and transmission operator must demonstrate that the Critical Equipment Monitoring Document is kept current at all times and that the documented tools/procedures are used as intended*.

PM1.2.1. Each reliability coordinator and transmission operator must demonstrate, upon request, its capability to monitor critical equipment via automated tools (e.g., critical equipment status displays or visualization tools) or organizational processes (e.g., trouble notification processes) as stated in Requirement PR1.2.1.

PM 1.3 Each reliability coordinator and transmission operator must demonstrate that the event logs as stated in Requirement PR1.3 contain the required information.

PM 1.4 The Critical Equipment Maintenance and Testing Document must be available as specified in PR1.4.

Rationale

The "Purpose" section of Standard IRO-005 states, "The Reliability Coordinator must be continuously aware of conditions within its Reliability Coordinator Area and include this information in its reliability assessments. The Reliability Coordinator must monitor Bulk Electric System parameters that may have significant impacts upon the Reliability Coordinator Area and neighboring Reliability Coordinator Areas." RTBPTF believes that information on critical equipment status is essential to the RC's continuous awareness of conditions that may impair the RC's ability to operate the bulk electric system reliably. Lack of awareness that critical equipment was unavailable was a significant element contributing to the August 14, 2003 Blackout, as noted in the *Outage Task Force Final Blackout Report*. If a new requirement is not established for monitoring of critical equipment, there will be no way to ensure that operators are aware when critical equipment, such as servers, is unavailable.

RTBPTF included TOPs in the recommendation above because these entities are subject to the recommended Reliability Toolbox requirement and are required to have the critical equipment that provides the infrastructure for the Reliability Toolbox tools.[12]

Recommendation – G13

Establish a change management process for performing critical equipment maintenance, modification, and testing.

Recommendations for Operating Guidelines

RTBPTF recommends development of the following operating guidelines for the facilities monitor application. These operating guidelines support the recommended additional requirements to Standard IRO-005-1 stated above.

Recommendation – G14

Develop a notification process when critical equipment is unavailable and an analysis/resolution process for critical equipment failures.

- Each reliability coordinator should have a demonstrated critical equipment monitoring process. This monitoring process should have the objective/purpose of enhancing operator awareness of the availability of critical equipment. The monitoring process should, at a minimum, include:
  - Notification of management, operator, and support personnel when critical equipment is unavailable
  - An analysis and resolution process for critical equipment failures

[12] See the Reliability Toolbox Rationale and Recommendation section as well as the recommendations for each tool in the Reliability Toolbox.

Recommendation – G15

Develop a critical monitoring application that interfaces to alarm tools and logs all events related to the equipment failures.

- Each reliability coordinator should have a facilities monitoring application, which has, at a minimum, the following capabilities:
  - Interface of facilities monitoring application to alarm tools
  - Audit logging of all events related to critical equipment failures

Areas Requiring More Analysis

RTBPTF identified no areas requiring additional analysis for facilities monitoring.

Examples of Excellence

RTBPTF cites American Electric Power's use of a facilities monitor application by Central and Southwest (CSWS) as an example of excellence (See EOE-19 in Appendix E). CSWS interfaces their facilities monitoring application with their critical applications monitor application.

Section 5.4
Critical Applications Monitoring

Definition

The critical applications monitor tracks the status of critical real-time tools. This application allows operators and/or support group personnel to track availability of critical real-time tools. Critical real-time tools must be available for operators to monitor, assess, and perform the necessary actions to maintain the reliability of interconnected bulk electric systems. A critical applications monitor tool may be part of a facilities monitoring tool (see Section 5.3, Facilities Monitoring).

Background

As discussed in detail in Section 5.0, Support and Maintenance Tools, situational awareness of the status and availability of critical real-time tools is an essential component directly related to reliability. The Outage Task Force Final Blackout Report stated that FE's computer support staff was unaware of the failure of their alarm tools application. FE had no alarm tools failure detection system. When the FE alarm processor stopped functioning properly, computer support staff remained unaware of this failure until a second EMS server failed approximately 40 minutes later. Because FE had no periodic diagnostics to evaluate and report the state of their alarm tools, support staff were not alerted to the eventual failure of two EMS servers or the infinite loop lockup failure of the alarms — or that the alarm processor had failed in this manner earlier and independently of the server failures. This illustrates the importance of having monitoring tools that report unavailability of critical real-time tools. Operators need to be aware when their ability to monitor the bulk electric system has degraded. Proper notification of maintenance and support personnel is requisite for real-time operations.

Summary of Findings

All respondents to the critical applications monitor portion of the Real-Time Tools Survey indicate that they have an operational critical applications monitor tool that offers the same functionality as defined in the survey. Additionally, all respondents rate their critical applications monitor as either “essential” or “desirable” for situational awareness. The majority (88 percent) rate it “essential,” and not one entity rates it having “minimal value” or “no value.” One respondent states that “this tool has dramatically improved… state estimator availability and…ICCP data availability.” This majority rating was consistent across all entity types, as shown in Table 5.4-1.

Entity Type	How do You Rate the Value of Your EMS Critical Applications Monitor as a Critical Support Tool to Enhance Reliability Operation and Situational Awareness?	
	"Essential"	"Desirable"
All	35/40=88%	5/40=12%
RC	13/15=87%	2/15=13%
Others	22/25=88%	3/25=12%

Table 5.4-1 — Value of Critical Applications Monitor, by Entity Type

The survey results reveal that, although the majority of respondents consider the critical applications monitor tool essential, there is a significant variation in practice, implementation, and usage of the tool. Therefore, this tool is a logical candidate for standardization. The survey asked respondents to identify the types of critical applications that are monitored by their organizations. A consistent majority of respondents monitored the critical applications listed in the survey (see Table 5.4-2). Other entities also monitor automatic generation control (AGC) and market applications.

Applications	All	RC	Others
Alarm Tools	36/40=90%	12/15=80%	24/25=96%
State Estimator	28/40=70%	13/15=87%	15/25=60%
Contingency Analysis	25/40=63%	12/15=80%	13/25=52%
SCADA	37/40=93%	13/15=87%	24/25=96%
Inter-Utility Link Data Application	33/40=83%	12/15=80%	21/25=84%

Table 5.4-2 — Applications Tracked by Critical Applications Monitor, by Entity Type

The survey results indicate that the majority of entities have tools and processes to monitor applications that are critical to continuous operation of their control centers. This encouraging result shows that critical applications monitoring is a prevailing industry practice. Critical applications monitoring is important not only for computer support but also for reliable operation of the bulk electric system. Increasing operator awareness of critical real-time tool status increases situational awareness.

The survey also examines the functional features of critical applications monitor applications. All of the respondents can generate alarms based on critical real-time tools status, and the critical applications monitor interfaces directly to the alarm tools application. Of the entities that use this functional feature (interface to alarm tools), 82 percent rate it “essential” for situational awareness. These data suggest that situational awareness is enhanced if the critical applications monitor interfaces with the alarm tools application.

Operators at 72 percent of entities responding to the survey have access to visual representation of critical real-time tools status. Entities that have this functional feature rate it either “essential” (59 percent) or “desirable” (41 percent) for situational awareness. Entities that do not have this feature rate it “desirable” (73 percent) or of “minimal value” (18 percent), or “no value” (9 percent). These results indicate that a majority of the industry believes that visual representation of critical real-time tools status can enhance operator and support staff situational awareness.

Table 5.4-3 shows the percentages of respondents that have a critical applications monitor tool that can page support personnel when a critical real-time application is unavailable or stalled. Entities that have this feature rate it “essential” (56 percent), “desirable” (39 percent), or of “minimal value” (6 percent) for situational awareness. Entities that do not have this feature rate it “desirable” (40 percent), of “minimal value” (50 percent), or of “no value” (10 percent) for situational awareness. Table 5.4-3 shows that the majority of the industry has access to automatic paging from a critical applications monitor although other internal methods of notifying support personnel may be employed.

Response	All	RC	Others
Yes	20/40=50%	11/15=73%	9/25=36%
No	20/40=50%	4/15=27%	16/25=64%

Table 5.4-3 — Entities that Can Page Support Personnel When a Critical Real-time Tool is Unavailable or Stalled, as Determined by the Critical Applications Monitor Tool

The data are insufficient to evaluate the usage and implementation of survey respondents’ critical applications monitor tools. Ideally, to ascertain critical real-time tool status, the monitoring tool should be independent of the critical real-time tool being monitored. For example, if the critical applications monitor tool tracks the alarm tools application, the critical applications monitor tool and the alarm tools application should not reside on the same server. Further investigation is needed to determine whether this scheme is in use in the industry.

Recommendations for New Reliability Standards

Because continual monitoring of the availability of critical equipment/critical real-time tools is essential to for reliable power system operation, as supported by the survey results, RTBPTF recommends adding new critical applications monitoring requirements to existing standard IRO-005 (Reliability Coordination – Current Day Operations), to strengthen operator situational awareness.

Critical applications monitoring requirements could, in principle, also be added to NERC’s cyber security standards CIP-002 through CIP-009, which address securing critical cyber assets and requiring that tools and processes be established so that minimum security controls are in place to protect critical equipment. Specifically, Standard CIP-007, Requirement 6 mandates that responsible entities ensure that all cyber assets within the electronic security perimeter, to the degree technically feasible, implement automated tools or organizational process controls to monitor system events related to cyber security. However, Standard CIP-007 does not explicitly address operator awareness of critical applications that may affect the reliable operation of the bulk electric system; rather, it focuses on automated tools or organizational process controls to monitor system events related to cyber security only. Therefore, RTBPTF recommends adding the critical applications monitoring requirements to Standard IRO-005. This standard is a more appropriate location for the requirements because the purpose of IRO-005-1 is to ensure operator awareness of bulk electric system parameters.

RTBPTF Recommendations

The requirements recommended for addition to existing Standard IRO-005 are stated below. The full text of interrelated requirements applicable to critical equipment, which comprises three areas, (change management tools and practices (Section 5.2), facilities monitoring (Section 5.3), and critical applications monitoring) is presented here for clarity. The requirements related to the topic of this section of the report, critical applications monitoring, are highlighted in italic font:

PR1. *Each reliability coordinator and transmission operator shall monitor and maintain awareness of critical equipment status to ensure that the unavailability of critical equipment does not impair the reliable operation of the bulk electric system. Other entities supporting or complementing the reliability coordinator's or transmission operator's ability to operate the bulk electric system reliably shall be subject to the same requirements as the reliability coordinator or transmission operator respectively.*

PR1.1. *Identification of critical equipment — Each reliability coordinator and transmission operator shall identify the critical equipment it uses for bulk electric system operation and monitoring. This includes the critical equipment of parties to whom the reliability coordinator or transmission operator has delegated reliability functions. Each reliability coordinator and transmission operator shall maintain a Critical Equipment Identification Document that lists all critical equipment. The Critical Equipment Identification Document shall be kept current at all times.*

PR1.1.1. *Each reliability coordinator and transmission operator shall include, at a minimum, the following list of critical real-time tools used in the operation and monitoring of the bulk electric system: alarm tools, telemetry data systems (includes applications for SCADA and ICCP Data Link telemetry data), state estimator, network topology processor, and contingency analysis.*

PR1.1.2. Each reliability coordinator and transmission operator shall include, at a minimum, the following list of critical equipment used in the operation and monitoring of the bulk electric system: servers or computers that contain the critical real-time tools specified above and the data links that provide the input to the critical real-time tools specified above.

PR1.2. *Monitoring of Critical Equipment — Each reliability coordinator and transmission operator shall maintain a Critical Equipment Monitoring Document identifying its tools and procedures for monitoring critical equipment (which includes critical real-time applications). This document shall describe how to verify that the tools and procedures are functioning and being used as intended. This document shall describe the tools and procedures for operator notification when critical equipment is unavailable.*

PR1.2.1. Each reliability coordinator and transmission operator shall implement automated tools or organizational processes to monitor critical equipment (which includes critical real-time applications) and related system events to ensure reliable operation of the bulk electric system. These tools or organizational processes shall be described in the Critical Equipment Monitoring Document.

PR1.3. Each reliability coordinator and transmission operator shall maintain event logs pertaining to critical equipment (which includes critical real-time applications) status for a period of one year. At a minimum, the event logs shall contain the following information regarding any event that affects the functionality and/or availability of critical equipment. The event log shall address the following questions: What happened? When did it happen? Who was notified? What was the resolution?

PR1.4. Maintenance of Critical Equipment — Each reliability coordinator and transmission operator shall maintain a Critical Equipment Maintenance and Testing Document identifying its tools and procedures for maintenance, modification, and testing of critical equipment. This document shall describe how to verify that the tools and procedures are functioning and being used as intended.

RTBPTF recommends the following measures for the requirements stated above. The measures related to change management tools and practices are written in italic font.

PM 1. *Measures for Critical Equipment Monitoring*

PM 1.1 *The Critical Equipment Identification Document must be available as specified in Requirement PR1.1. Additionally, each* *reliability coordinator and transmission operator shall demonstrate that the Critical Equipment Identification Document is kept current at all times.*

PM1.1.1. *As specified in Requirement PR1.1.1, the Critical Equipment Identification Document must contain, as part of its list of critical real-time applications, the following applications: alarm tools, telemetry data systems (includes applications for SCADA and ICCP Data Link telemetry data), state estimator, network topology processor, and contingency analysis.*

PM1.1.2. As specified in Requirement PR1.1.2, the Critical Equipment Identification Document must contain, as part of its list of critical equipment, the following equipment: servers or computers that contain the critical real-time tools, and the data links that provide the input to the critical real-time tools specified.

PM 1.2 *The Critical Equipment Monitoring Document must be available as specified in PR1.2. Additionally, each reliability coordinator and transmission operator must demonstrate that the Critical Equipment Monitoring Document is kept current at all times and that the documented tools/procedures are used as intended*.

PM1.2.1. Each reliability coordinator and transmission operator must demonstrate, upon request, its capability to monitor critical equipment via automated tools (e.g., critical equipment status displays or visualization tools) or organizational processes (e.g., trouble notification processes) as stated in Requirement PR1.2.1.

PM 1.3 Each reliability coordinator and transmission operator must demonstrate that the event logs as stated in Requirement PR1.3 contain the required information.

PM 1.4 The Critical Equipment Maintenance and Testing Document must be available as specified in PR1.4.

Rationale

The “Purpose” section of Standard IRO-005 states, “The Reliability Coordinator must be continuously aware of conditions within its Reliability Coordinator Area and include this information in its reliability assessments. The Reliability Coordinator must monitor Bulk Electric System parameters that may have significant impacts upon the Reliability Coordinator Area and neighboring Reliability Coordinator Areas.” RTBPTF believes that information on critical applications’ status is essential to the RC’s continuous awareness of conditions that may impair its ability to operate the bulk electric system reliably. Lack of awareness that critical real-time tools (e.g., FE’s alarm processor application) were unavailable significantly contributed to lack of operator situational awareness in the August 14, 2003 blackout, as noted in the *Outage Task Force Final Blackout Report.*

If a new requirement is not established for monitoring of critical real-time tools, operators may be unaware when these tools (such alarm tools or contingency analysis applications) are unavailable, which could impair their ability to monitor interconnected bulk electric system reliably.

RTBPTF includes TOPs in the recommendations stated above because these entities are subject to the Reliability Toolbox requirement and are required to have the critical equipment that provide the infrastructure for these tools.[13]

Recommendation – G16

Develop a process for monitoring critical real-time tools including change notification, status update, and severity of a situation.

Recommendations for Operating Guidelines

The survey results show that critical applications monitors are widely used by all types of entities in the industry. Although the survey did not quantify the tool's effectiveness, it is clear that awareness of the availability and status of critical real-time tools increases operators' situational awareness, which is essential for reliability monitoring as required by existing NERC standards. Because of the prevalence of critical applications monitor use, the following recommended operating guidelines appear feasible.

RTBPTF recommends development of the following operating guidelines for the critical applications monitor application. These guidelines support the recommended additions to Standard IRO-005-1 described above.

- Each reliability coordinator should have a demonstrated process for monitoring critical real-time tools. This monitoring process should have the objective/purpose of enhancing operator awareness of the availability of critical real-time tools. The monitoring process should, at a minimum, include the following:
    - Notification of management, operators, and support personnel when critical real-time tool are unavailable
    - Analysis and resolution process for critical real-time tool failures

[13] See the Reliability Toolbox Rationale and Recommendation section as well as the recommendations for each tool in the Reliability Toolbox.

- Critical real-time tool status should, at a minimum, be one of the following: (a) available — running, (b) available — stalled, or (c) unavailable. For example, if the critical real-time tool is functioning correctly (i.e., the output data are updating), the application would be deemed AVAILABLE — RUNNING. If for some reason, the application process/task is still alive but the output data from the application are not updating (because of internal application problems/issues), the application would be deemed AVAILABLE — STALLED. If the application/process is dead or non-existent (e.g., the application failed because of a core dump), the application would be deemed UNAVAILABLE.
    - If possible, the critical applications monitor should specify the severity of the situation, i.e., indicate the action to take to return the tool to AVAILABLE — RUNNING status. "High severity" would mean that a total system reboot is necessary to correct the UNAVAILABLE state.

Recommendation – A17

Investigate whether critical application monitor tools should be independent of the critical real-time tool being monitored.

Areas Requiring Additional Analysis

Ideally, in order to ascertain critical real-time tool status, the critical applications monitor tool should be independent of the critical real-time tool being monitored. For example, if the critical applications monitor tool monitors the alarm tools application, the critical applications monitor tool and the alarm tools application should not reside on the same server. Further investigation is needed to determine the prevalence of the use of this scheme throughout the industry.

Examples of Excellence

RTBPTF cites Tennessee Valley Authority's use of a critical applications monitoring tool that monitors all critical and non-critical processes on their SCADA system as an example of excellence (See EOE-20 in Appendix E).

RTBPTF cites International Transmission Company's use of a critical applications monitoring tool that that monitors the status of their state estimator and ICCP data applications as an example of excellence (See EOE-21 in Appendix E).

RTBPTF cites American Transmission Company's use of overview displays that not only show system performance but also EMS health checks as an example of excellence (See EOE-22 in Appendix E). These overview displays allow the system operator to determine whether the EMS is operational and functioning properly.

RTBPTF cites Central and Southwest's use EMS Facilities Monitoring application with its critical applications monitor as an example of excellence (See EOE-23 in Appendix E).

Section 5.5
Trouble-Reporting Tool

Definition

A trouble-reporting tool allows control center tools/applications users (operators and support personnel) to document problems (e.g., application, system, and display difficulties and malfunctions) and resolutions.

Background

RCs, TOPs, and BAs depend on real-time tools to operate the bulk electric system in a coordinated manner and ensure reliable operations under normal and abnormal conditions, as defined in the NERC standards. A trouble-reporting tool allows users to document problems related to critical real-time tools and may also be used to improve existing support processes.

Support processes help ensure the viability of systems and applications that underpin reliability functions in a control center. These processes allow operators to manage control center infrastructure, which evolves as a result of regular technology changes. Computer system outages and lack of infrastructure stability often result from lack of effective support processes, increasing the risk that critical equipment and real-time tools, used by operators to monitor, assess, or perform the actions necessary to maintain the reliability of the bulk electric system, will not be available. As part of support processes, trouble-reporting tools improve computer operations and help control and keep track of trouble report status (e.g., current computer system issues and their estimated time of repair) that may affect operators' situational awareness.

Summary of Findings

Most respondents (67 percent) to the trouble-reporting tool section of the Real-Time Tools Survey have an operational trouble reporting tool. RCs are most likely to use trouble-reporting tools; 94 percent of RCs responding to the survey have these tools. Table 5.5-1 summarizes the survey results.

Entity Type	Percentage of Entities That Have Operational Trouble Reporting Tools
All	31/46=70%
RC	16/17=94%
Others	15/29=52%

Table 5.5-1 — Entities with Operational Trouble-Reporting Tools

Most respondents that have an operational trouble reporting tool rate it "essential" (61 percent) or "desirable" (35 percent) for situational awareness. A minority of respondents (3 percent) rate their trouble-reporting tool as having "no value." One respondent that rates the tool "essential" states that "the Trouble Reporting Tool is used for having an indication of the usage of the EMS Production Support Resources. Additionally, special application incidents, incident reports, and Software Incident Reports are generated and tracked." "Essential" ratings varied across entity types (see Table 5.5-2) although RCs were most likely (88 percent) to assign this rating.

Entity Type	**How do You Rate the Value of Your Trouble Reporting Tool as a Critical Support Tool to Enhance Reliability Operation and Situational Awareness?**		
	"Essential"	**"Desirable"**	**"No value"**
All	19/31=61%	11/31=35%	1/31=3%
RC	14/16=88%	2/16=13%	0/16=0%
Others	5/15=33%	9/15=60%	1/15=7%

Table 5.5-2 — Value of Trouble Reporting, by Entity Type

The survey results also show that for most entities (93 percent), the trouble-reporting tool is a stand-alone application that is not integrated into EMSs. No tool features emerged as predominant among entity types. The following features were addressed in the survey:

- Display Attachments — This function allows users to attach displays or bitmap images to a trouble report. This feature allows users to efficiently describe a problem by attaching a display or bitmap image of it. (Forty-seven percent indicate that they have this feature, and 27 percent indicate that this feature is "essential" for situational awareness).
- Summary Reports — This function allows users to generate summaries (e.g., trouble reports by functional area) for analysis of trends. (Fifty-nine percent indicate that they have this feature, and 36 percent indicate that it is "essential" for situational awareness).
- Direct User Feedback — This function allows the application to indicate who originates a trouble report and the current status of the report. (Sixty-two percent indicate that they have this feature, and 28 percent indicate that this feature is "essential" for situational awareness).

Recommendations for New Reliability Standards

RTBPTF does not recommend any new reliability standards requiring use of a trouble-reporting tool. RTBPTF believes that the recommendations in Section 5.2, Change Management Tools and Practices, are sufficient to support operator situational awareness related to critical equipment and critical real-time tool maintenance, modification, and testing processes. RTBPTF believes that the trouble-reporting tool is useful and could be integrated with support processes required by the standards recommended in Section 5.2. The trouble-reporting tool could be used formally to document support processes.

Recommendations for Operating Guidelines

The survey results show that trouble-reporting tools are not as prevalent among industry entities as other tools despite the perceived value of trouble-reporting tools for enhancing support processes. The survey results did not quantify the effectiveness of the trouble-reporting tool, but it appears clear that having a tool to track problems and resolutions related to critical equipment and critical real-time tools will enhance situational awareness for both support personnel and operators. However, because change management processes vary in the industry, RTBPTF does not recommend development of new operating guidelines for trouble-reporting tools at this time. Operating guidelines recommended in Section 5.2 are sufficient.

Areas Requiring Additional Analysis

RTBPTF identified no areas requiring additional analysis for trouble-reporting tools.

Examples of Excellence

RTBPTF cites Florida Power and Light's (FPL) Trouble Report System, which facilitates logging, communication, and tracking of user problems with tools and systems maintained by the computer support group at FPL's System Control Center as an example of excellence (See EOE-24 in Appendix E). In addition to allowing entries of new trouble reports, the application performs administrative functions and can produce different query-based summary reports.

Section 6.0
Next Steps

NERC and the industry have much work to do to implement the RTBPTF recommendations described in this report for revised standards and operating guidelines to improve electric system reliability through better real-time operating tools and practices. In addition, NERC and the industry have much to do to conduct the necessary additional analyses of issues for which the task force could not provide specific, technically defensible recommendations or that were outside task force's scope.

To initiate the next steps in the process, RTBPTF proposes to finish work on the specific activities discussed below, which will complete the remainder of the task force's scope of work as assigned by the NERC Operating Committee (OC). Following completion of these activities, RTBPTF will disband.

RTBPTF's recommendations are intended to inform the standards development process. With assistance from NERC staff, RTBPTF will append its recommendations for revised standards to the existing Standards Review Forms that are included in the NERC Standards Development Plan: 2007–2009.[14] The relevant recommendations will be added to the "To Do List" section of the form for each affected standard along with other issues already identified from various sources such as the *FERC Staff assessment* of the NERC standards and comments on the standards from various industry stakeholders. As the standards development plan proceeds, RTBPTF will provide technical support to the standards drafting teams that will author the necessary revisions in accordance with the NERC Reliability Standards Development Procedure.[15]

RTBPTF will also prioritize the areas that the task force identified as requiring more analysis. For areas that the task force believes must be addressed by a new team of experts, RTBPTF will offer to write high-level scopes of work in the form of bullet points that the new teams should consider in drafting their own charters. RTBPTF will deliver the prioritized list of areas needing additional analysis to the NERC ORS and will prepare scope-of-work bullet points as requested by the ORS.

---

Recommendation – I6

Provide adequate funding and staffing for maintaining and upgrading real-time tools.

RTBPTF also recommends that others take two important additional steps that are outside the scope that the OC assigned to the task force. First, the task force recommends that the OC direct the ORS to determine how operating guidelines are to be developed and maintained. Consistent with the work already done by the ORS in this area, RTBPTF suggests that ORS consider asking the regional reliability organizations (RROs) to develop operating guidelines as "supplements" to NERC standards. Second, the task force urges NERC to develop a plan to address each of the "six major issues" identified by RTBPTF and described in the Introduction to this report.

RTBPTF does not take a position on the disposition of the Examples of Excellence listed in Appendix E of this report. They are presented for consideration by NERC and the industry, with the disclaimers noted in Appendix E.

Glossary of Terms Used in this Report

The following are definitions of terms used throughout this report. The report also contains terms as defined in the "Reliability Standards for the Bulk Electric Systems of North America" document.[1]

Term	Definition
Alarm tools	Applications that emit real-time visible and audible signals to alert operators to events and conditions affecting the state of the bulk electric system. Alarm tools can be external, embedded within the SCADA/EMS system, or a combination of both.
Automatic safety bet	Visualization tool that provides the tools/displays for operators to monitor, initiate, or disable triggering of schemes that shed firm load for under voltage or under frequency conditions. Automatic safety net could work with a remedial action scheme monitor.
Outage Task Force Final Blackout Report	U.S.-Canada Power System Outage Task Force. 2004. *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations*. April.
Bulk Electric System Elements List	A term developed by RTBPTF to refer to a list of specific bulk electric system elements (generators, transmission lines, buses, transformers, breakers, etc.) within an RC area. The Bulk Electric System Elements List shall contain the necessary bulk electric system elements (within the RC area) so that potential or actual SOL/IROL violations could be identified.
Change management tools	Tools and practices used by support personnel to maintain, modify, and/or test critical equipment that operators use to monitor and perform necessary actions to maintain reliability of the bulk electric system.
Commercial/industrial demand-side management	See "Commercial/industrial load management"
Commercial/industrial load management	Tools that enable operators to curtail commercial/industrial electric demand. This type of tool is similar to residential load or demand-side management but is applied to commercial/industrial customers. A typical application of this type of tool is the disconnection of the electric supply feed from the supplying entity through direct computer control by operators to reduce electric demand.
Congestion management application	Application used for relieving network congestion within an entity's service territory using operational means that lie within the entity's control authority, e.g., generation redispatch, curtailment of transactions within the entity's service area, capacitor bank switching, opening low voltage lines, etc. Typically, it may be a security-constrained dispatch program, an optimal power-flow program, or a heuristic program that searches for the best solution from a set of options. For an ISO or an RTO, this may be part of the LMP application.

[1] For these terms, please refer to the Glossary in the latest official copy of the NERC Reliability Standards, which can be found at http://www.nerc.com/~filez/standards/Reliability_Standards_Regulatory_Approved.html.

Term	Definition
Contingency analysis	Computer application used to analyze the impact of specific, simulated outages (lines, generators, or other equipment) or higher load, flow, or generation levels on the security of the system. Contingency analysis identifies problems such as line overloads or voltage violations that will occur if a new event (contingency) happens on the system. The state estimator solution is a representation of current system conditions and usually serves as the base case in the analysis. The information a contingency analysis generates enables RCs and TOPs to implement mitigation plans in advance of a contingent event such as a line trip. Contingency analysis is used as a real-time application as well as for studying potential scenarios.
Critical applications monitoring	Tracks the status of critical real-time tools. This application allows operators and/or support group personnel to track availability of critical real-time tools. Critical real-time tools must be available for operators to monitor, assess, and perform the necessary actions to maintain the reliability of interconnected bulk electric systems. A critical applications monitor tool may be part of a facilities monitor tool.
Critical equipment	Installed equipment that makes up the infrastructure and systems (including communication networks, data links, hardware, application software, and databases) that are directly used as the computer infrastructure for critical real-time tools. Critical equipment is essential for all reliability entities to ensure the reliable operation of the bulk electric system. Critical equipment is a subset of critical cyber assets.
Critical facility loading assessment	Application that evaluates a set of contingencies and calculates the post-contingency loading of a set of monitored facilities using telemetered SCADA flows and LODFs. CFLA may be used as a backup application if the state estimator and/or contingency analysis applications fail.
Critical real-time tool	Installed software that is essential to support, operate, or otherwise interact with bulk electric system operations. Critical real-time tools do not include process control applications, distributed control system applications installed in generating stations, switching stations, or substations.
Display maintenance tool	Tool used by support personnel to develop and maintain visual interfaces that operators use to maintain situational awareness, i.e., to monitor and assess bulk electric system reliability and/or take action to maintain system reliability.
Dynamic mapboard	Physical collection of painted lines, status lights, and analog readouts presenting, in a stationary prominent location, continuous real-time status of important selected components of the power system to operators. It is “dynamic” because the statuses of important selected components of the power system are updated in real time. A dynamic mapboard usually complements common SCADA/EMS displays.

Term	Definition
Dynamic overview display	One-line and other graphical displays depicting the state, loading, and/or voltage levels over the wider area (or a sub-area within the entity's internal footprint) of the power system. Dynamic overview displays are essentially large SCADA one-line displays. Examples of this type of visualization tool are area overview one-line displays, which are one-line displays that show a group of electrically connected substations for a specified area.
Dynamic stability assessment	Application (or a suite of applications) executing in near-real time that aid in determination of system operating limits based on transient dynamic stability assessment using a current state estimator model of the real-time system. A dynamic stability assessment may also provide an indication of the dynamic stability margin for the most critical fault/contingency condition.
Emergency tools	Applications or procedures that operators use when the power system enters or is about to enter an emergency. The NERC Glossary defines "emergency" as "[a]ny abnormal system condition that requires automatic or immediate manual action to prevent or limit the failure of transmission facilities or generation supply that could adversely affect the reliability of the Bulk Electric System."
Facilities monitor	Tracks the status of computer systems equipment, servers, backup systems, communications systems, networks and other critical facilities. This tool allows operators and/or support personnel to be aware of critical equipment issues that may affect the availability of critical real-time tools used to operate and monitor the bulk electric system.
Flowgate monitor	Visualization tool that provides the tools/displays for operators to monitor actual and contingency flows on designated flowgates. The NERC Glossary defines "flowgate" as "[a] designated point on the transmission system through which the Interchange Distribution Calculator calculates the power flow from Interchange Transactions." This type of visualization tool provides flowgate information to operators; it could run either within or independent of SCADA/EMS systems.
Inter-control center communications protocol	Inter-Control Center Communications Protocol (ICCP) is a standard data exchange protocol that is widely used in the electric utility industry to communicate information between operating entities. The NERC ISN utilizes ICCP to support data exchange among RCs, and several intra-regional and intra-company networks also use this protocol to support the provision of data to RCs from operating entities within the RC area.
Inter-regional real-time coordination for market redispatch	Application used to adjust the market dispatch within the entity's service territory in coordination with adjacent RCs to manage the inter-regional congestion problem in real-time. This tool may be handled by the entity's congestion management application, or it may be handled through a different process.

Term	Definition
Inter-regional voltage profile coordination	Application that coordinates the voltage profiles between two or more regions. This application may contain features such as wide-area voltage contour visualization, voltage schedule coordination between regions, etc.
Line outage distribution factor	Estimation of impact from an outage over a facility can be done using LODF. In general, an outage impacts the system by transferring the amount of power flowing on the outaged elements during pre-contingency conditions to other facilities in the system. These changes could increase or decrease power flow on the facilities depending on network topology, load, and generation dispatch. LODF is formulated as a percentage of pre-contingency flow on the outaged line that appears on the monitoring facility during contingency conditions.[2]
Load reduction by voltage reduction	Enables the operator to curtail electricity demand by reducing the distribution-level voltages. This scheme usually involves direct computer control (via SCADA systems) to automatic voltage regulating relays on LTC power transformers and step voltage regulators. By means of the control of the dry contact closure to the regulating relay, its regulating center band voltage is reduced to a lower level by boosting the sensed voltage of the voltage regulating relay. This causes a reduction of the distribution voltage schedule, which reduces electricity demand for a short period.
Locational marginal pricing	A market-pricing approach used to manage the efficient use of the transmission system when congestion occurs on the interconnected bulk electric system.
Network topology processor	SCADA-based application that determines facility status and station configuration based on breaker and switch status data. The processor converts a nodal network model into a bus-branch model, for use by other applications such as the state estimator. It may perform the same function for study network applications such as power flow.
Offline power flow	See "Power Flow"
Online power flow	See "Power Flow"
Operator	System operator
Power flow	Application used to calculate the state of the power system (flows, voltages, and angles) by using available input data for load, generation, net interchange, and facility status. Power flow is divided into two categories: "online power flow" and "offline power flow." An "online power flow" application is typically integrated within an EMS (or has a direct data feed from an EMS) and utilizes node-breaker topology whereas "offline power flow" is based on bus-branch models and static data. Power flow is widely used in real-time systems to assess system conditions or perform look-ahead analysis. Power flow is also used to study "n-1" contingencies and to identify potential future voltage collapse or reliability problems.

[2] Source: http://www.caiso.com/docs/2005/05/03/200505031714217356.pdf.

Term	Definition
Reactive reserve monitor	Visualization tool that allows operators to monitor reactive reserves (from static and dynamic sources) in local geographic areas or major load centers. This visualization tool can alarm the operator when a generating unit has reached its reactive capability or an area has approached the minimum reactive reserve requirement. This type of visualization tool could also be the real-time user interface representation of the documented set of procedures, practices, or guidelines for maintaining awareness of the current and near-term reactive reserve capability.
Real-Time Tools Best Practices Task Force	The task force responsible for this report
Real-time contingency analysis	See "contingency analysis"
Remedial action scheme monitor	Visualization tool that provides the tools/displays for operators to monitor the status of critical power system parameters and measure the proximity of these parameters to the triggering conditions for special protection schemes or total system failure. This tool alarms and advises operators of actions required to mitigate the pending power system condition.
Residential demand-side management	See "residential load management"
Residential load management	Enables the operator to curtail residential electric demand for specific appliances. Residential load or demand-side management (DSM) consists of planning, implementing, and monitoring activities designed to encourage residential consumers to modify their level and pattern of electricity usage. These activities are also designed to shape electricity demand through direct computer control of specific appliances. For example, when necessary, operators could turn off air conditioners of residential customers that sign up for a residential DSM program.
Rotating load shed	Enables the operator to curtail load by initiating or scheduling load shedding. The *Outage Task Force Final Blackout Report* defines "load shedding" as "… the process of deliberately removing (either manually or automatically) pre-selected customer demand from a power system in response to an abnormal condition, to maintain the integrity of the system and minimize overall customer outages." For this type of tool, rotating load shed refers only to manual load shedding scheduled or initiated by operators via computer control.
SCADA one-line display	Dynamic, one-line diagram displays of substations and major power system components that present the real-time status and selected flow, voltage, and other data of the power system. This is the most common type of visualization tool used today to monitor bulk electric system elements or parameters.
Security-constrained dispatch	See "congestion management application"
Selectable data trending	Visualization tool that provides the ability to plot graphically selected power system values, using up-to-date data on the plot at a reasonable refresh rate on real-time displays used by operators and others. Displays are used by system operators and others.

Term	Definition
Short-term load forecasting	Application that predicts short-term (next 0-60 minutes) loads based on parameters such as short-term weather effects, current load, etc. The result from this tool could be used for predictive redispatch, look-ahead contingency analysis, awareness of scheduled non-conforming load changes, etc.
Short-term weather forecasting	Application that predicts short-term (next 0-60 minutes) extreme weather that may impact operations, e.g., a lightning prediction tool, Doppler radar, etc.
Short-term wind energy forecasting	Near real-time application that is used to predict and manage generation in response to the variability of supply from wind-energy sources.
Short-term hydro scheduling	Real-time application used to manage deviations from the long-term optimized schedule (for hydro units) for reasons of reliability, e.g., a response to a DCS event, acquiring support for localized voltage control, etc.
State estimator	Application that performs statistical analysis using a set of imperfect, redundant, telemetered power system data to determine the system's current condition. The system condition or state is a function of several variables: bus voltages, relative phase angles, and tap changing transformer positions. A state estimator can typically identify bad analog telemetry, estimate non-telemetered flows and voltages, and determine actual voltage and thermal violations in observable areas. The state estimator application has two main uses. It provides (1) a base case for reliability-analysis applications, and (2) input to other system monitoring tools. The state estimator solution is typically used as the base case for other reliability-related applications, such as contingency analysis. In some cases, the state estimator is used primarily as the basis for information communicated to operators regarding power system status, e.g., the state estimator drives the alarm application that alerts operators to power system events.
State estimator one-line display	Dynamic, one-line diagram displays of substations and major system components that present the state estimator solution for status and selected flow, voltage, and other data from the power system.
Study area one-line display	Study area one-line displays are one-line diagram displays of substations and major system components that present the active study context of status and selected flow, voltage, and other data from the power system model in use. Examples of this type of visualization tool are power flow one-line displays, contingency analysis one-line displays (for a specified contingency), etc.
Study real-time maintenance	Application that simulates real-time network applications (e.g., NTP, state estimator, contingency analysis, etc.) and debugs problems without affecting the operation of the real-time applications. Can be an on-line application integrated with the production EMS system, an application integrated with a non-production EMS system (i.e., DTS, etc.), or an off-line application.

Term	Definition
Telemetry data	Status and analog values originating from conventional SCADA/EMS or equivalent systems (telemetry data systems) and are updated continuously in real-time or near-real-time operation. These data may come directly from SCADA system(s) or from direct connection (ICCP, ISN, etc.) to SCADA systems operated by others.
Telemetry data systems	Tools or applications that process and provide telemetry data. SCADA is an example of a telemetry data system.
Topology and analog error detection	Application that identifies and/or automatically overrides incorrect SCADA breaker and switch statuses to enhance a NTP and to improve the accuracy and robustness of the state estimator. May also identify and/or automatically ignore SCADA analog measurements that are unreasonable or inconsistent with network connectivity.
Transaction impact monitor	Type of visualization tool that provides the tools/displays for operators to monitor scheduled transactions and interchange flows between balancing authorities.
Trouble-reporting tool	Allows control center tools/applications users (operators and support personnel) to document problems (e.g., application, system, and display difficulties and malfunctions) and resolutions.
Visualization tools/techniques	A group of user interface applications, tools, or displays that provide concise visual monitoring and enhanced multiple views of relevant power system data in real time to operators and others. Visualization tools help operators monitor and better understand system events and/or conditions across neighboring power systems that may be affecting reliable operations in their part of the power system.
Voltage stability analysis	Application executing in near-real time that aids in determination of system operating limits based on voltage stability assessment using a current state estimator model of the real-time system. VSA may derive minimum voltages at key buses below which voltage collapse may occur under further stress to the system, evaluate whether sufficient stability margins exist for an analyzed base case, provide margins relative to particular stress modes such as transfers or system loading, or provide information on minimum dynamic reactive reserves required in local areas.
Wide-area view boundary	The NERC glossary defines “wide area” as “[t]he entire Reliability Coordinator Area as well as the critical flow and status information from adjacent Reliability Coordinator Areas as determined by detailed system studies to allow the calculation of Interconnected Reliability Operating Limits.” RTBPTF defines “wide-area view boundary” as the network model boundary for the “wide area.” For reliability coordinators, the “wide-area view boundary” defines the minimum required network model in order to support the monitoring requirements for the “wide area.” This network model should contain all the bulk electric system elements (generators, transmission lines, buses, transformers, breakers, etc.) bounded by the wide area view boundary.

Term	Definition
Wide-area visualization tools	Displays/tools driven by SCADA, EMS, PMU, disturbance recorder, and other technical data collected in real time that present concise information for the “wide area.” In general, these displays/tools show multiple views of the status of critical facilities within the entity’s internal footprint, but they are also used to show views of critical facilities or data from the entity’s external footprint that have the potential for adverse impact to the internal system (the “wide area” as defined in the NERC Glossary). By this definition, dynamic overview displays may also be considered wide-area visualization tools. Besides the traditional SCADA/EMS displays that show critical reliability parameters, wide-area visualization tools use other forms of technology/methodology to present vast amounts of information in a form such that the operator can assess the state of the system in an intuitive and quick manner.

Appendix A
Real-Time Tools Survey Development and Software

Introduction

RTBPTF's scope includes the assignment to "develop a focused survey (preferably web-based) for distribution to entities responsible for reliable operations to determine which tools those entities use to perform state estimation, perform real-time contingency analysis, and maintain situational awareness of their systems." To fulfill this assignment, the task force developed the Real-Time Tools Survey and delivered it as an interactive, on-line, web-based questionnaire. Lawrence Berkeley National Laboratory provided programming, database, and systems integration services for the survey. This Appendix summarizes the survey's development and briefly describes the software system that was created to support it, including its testing, quality assurance, and role in the survey analysis.

Summary of Survey Development

The survey in its final form was more than 300 pages long, with nearly 2,000 questions organized into five major sections: Real-Time Reliability Tools, Situational Awareness Practices, Real-Time Data Acquisition and Exchange, Modeling Practices, and Support and Maintenance Practices related to the real-time tools.

Real-Time Tools

The initial basis for the selection of the real-time tools investigated in the survey was a report on minimum requirements and best practices for reliability software, presented at a July, 2004 FERC technical conference on Information Technology for Reliability and Markets, (Docket No. PL04-12-000).[1] Starting from the applications addressed in that presentation, RTBPTF narrowed the list to real-time operator tools. (The task force did not consider long-term, medium-term, day-ahead, training, or market or economic operations tools.) Based on their collective expertise and experience, the task force members then developed a complete list of reliability tools that directly support situational awareness and formulated definitions for each tool. Special emphasis was placed on tools to aid operator situational awareness because the *Outage Task Force Final Blackout Report* repeatedly points to lack of operator situational awareness as a key cause of the August 14, 2003 blackout. The real-time tools portion of the survey was designed to elicit, from different types of entities responsible for reliable

[1] Macedo, Frank. Consultant to FERC. 2004. *Reliability Software Minimum Requirements & Best Practices*. FERC Technical Conference, July 14.
http://www.ferc.gov/EventCalendar/Files/20040716092511-20040714085315-FrankMacedo.pps

operation of the bulk electric system, descriptions of their use of each tool. The task force's goal was to characterize, based on the survey results, each tool's industry-wide status.

Situational Awareness Practices

The task force reviewed the then-current NERC reliability standards to identify elements of situational awareness that were addressed to some extent in the standards. These elements formed the basis for survey questions on operating practices, processes, and procedures used to maintain situational awareness.

Data, Modeling, and Support and Maintenance Tools

The three remaining sections of the survey address the acquisition and exchange of real-time data needed to support real-time reliability tools and practices, the characteristics of the real-time models needed to support those tools (as well as the practices used to build and maintain the models), and other tools and practices to support and maintain real-time reliability tools. These topics were included in the survey because real-time reliability tools require accurate input data, well-designed models, and effective maintenance to produce meaningful results that operators can depend on for situational awareness.

Survey Structure

Task force members extensively debated the optimal structure for the individual questions in the survey. Some members felt that asking general questions that required a detailed, free-format written response would elicit the most comprehensive and insightful information and thus the best basis for identifying candidates for follow-up questioning. The downside to this structure would have been the enormous challenge of analyzing the responses, especially for a questionnaire of this length.

Some task force members favored an alternative structure with sets of specific questions on a particular subject, each having yes/no or multiple-choice answers, designed to elicit, in the aggregate, a complete picture of a topic but requiring minimal effort from respondents. The upside of this approach is that the responses could be easily queried, sorted, and analyzed statistically. The downside is that respondents could not elaborate on their answers.

The final decision was to use a yes/no, multiple-choice structure but to give respondents the ability to add free-format written comments on key topics addressed in the questions.

Each section of the survey described above was broken into individual subsections that addressed specific tools or practices. Within each subsection, the questions were designed and arranged to: identify the types of entities using the tool or practice; inventory the functions of the tool or practice; and rate the value of the tool, function, or practice for situational awareness. In addition, survey respondents were asked to identify what they perceive as *best practices* in their control centers for the particular tool or practice.

The task force finished designing the survey in April 2005 and sent it to Lawrence Berkeley National Laboratory for programming. Beta testing began in June 2005, and the survey was rolled out to reliability coordinators (RCs), transmission operators (TOPs), and balancing authorities (BAs) in August 2005. The task force closed the survey in November 2005 and began analyzing the results in preparation for this final report. The task force presented an overview of its preliminary findings and recommendations to the NERC Operating Reliability Subcommittee (ORS) in November 2006.

Survey Hardware and Software

The RTBPTF on-line survey has two internal components: a web server, and a database, as illustrated in Figure A-1. A secure web server, maintained by NERC staff in Princeton NJ, hosted the survey software. The database stored the questionnaire structure and all of the users' responses. The software generated the web pages through which respondents navigated to read the questions and insert answers by reading directly from the design data (e.g., section, question number, question text, question type) stored in the questionnaire portion of the database. Figure A-2 shows examples of the user interface web pages. All communication between users and the questionnaire took place over an encrypted channel to ensure the security of users' responses. The software used to produce the web site and control the database is written in PHP (www.php.net), which interacts with a MySQL (www.mysql.com) database.

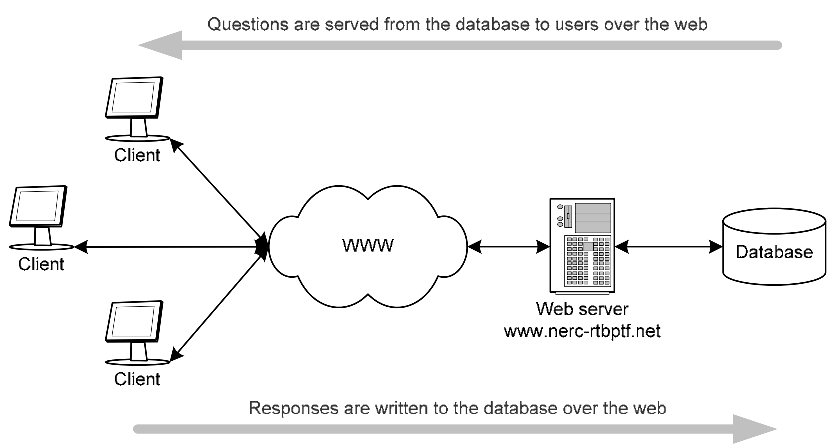

Figure A-1 — Software Communication

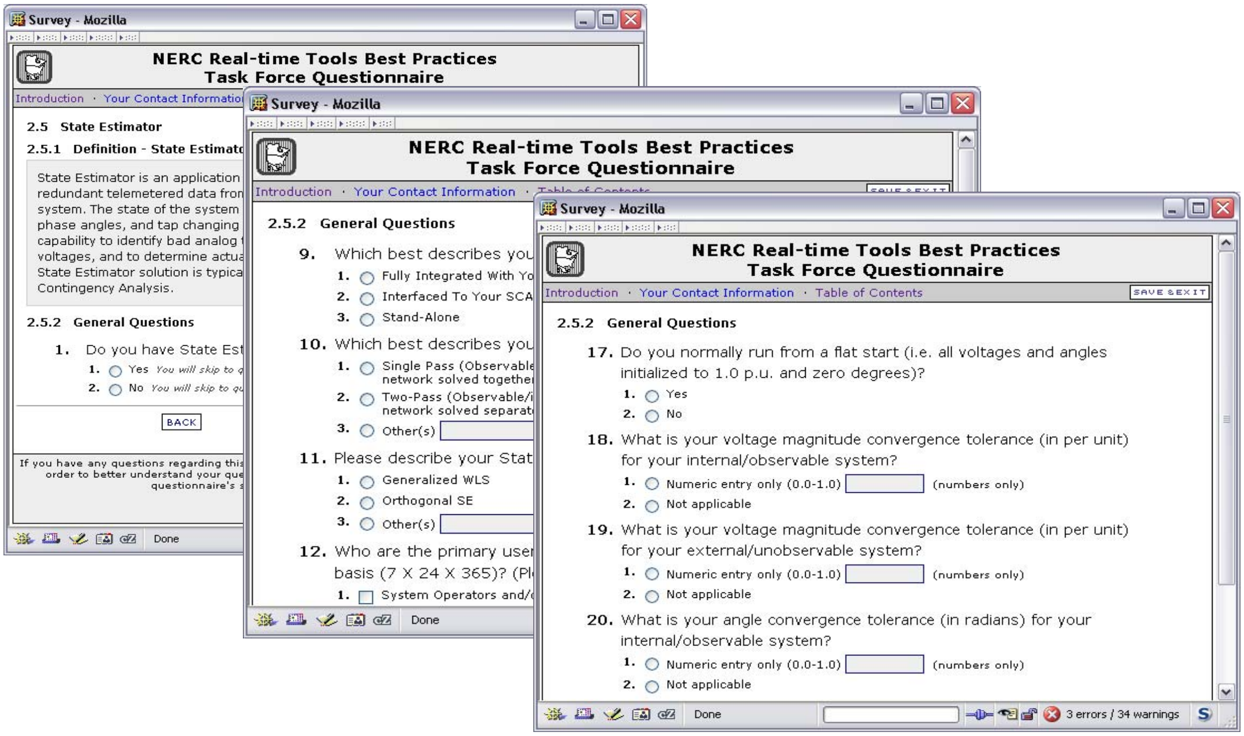

Figure A-2 — User Interface Web Page Examples

Testing

To ensure ease of use and confirm the accuracy of the software application, task force members tested it rigorously prior to release for both completeness and functionality (e.g., navigation among and within survey sections). Improvements in questionnaire content entailed adding or editing database records to add or edit questions. Improvements in questionnaire functionality (e.g., to aid navigation by respondents) entailed direct modifications to the interface software.

Quality Assurance

After the survey period ended, additional software tools were developed that were tailored to task force needs, to interrogate the database and assess consistency among and completeness of user responses. In a few cases, individual users were contacted to clarify conflicting responses.

Interfaces were built on the web server with the following functionalities:

- View survey completion counts by reliability region,
- Download aggregate results of all answers in spreadsheet format,
- View user profiles and download their surveys by reliability region, and
- View aggregate responses for individual questions.

Results/Deliverables

Final output from the questionnaire database was provided in two formats: 1) a report of aggregate responses for each survey question (which can be downloaded as pdfs at: http://www.nerc.com/~filez/rtbptf.html), and 2) the entire questionnaire database in Microsoft Access format.

The report of aggregate responses summarize all responses for each survey question. Responses are presented first aggregated for all respondents, followed by an aggregation of responses received from reliability coordinators.

To mask individual respondents' identities, all comments entered in free-format text fields were globally post-processed to remove references to a specific entity name. These references were replaced with a generic label or term, depending on the context.

The Microsoft Access database containing the raw survey responses is an abridged version of the master MySQL database. Data in the MySQL database specific to the functioning of the web site were not ported to the abridged version. Only data specific to the questions, answers, and respondents were included. The members of the task force received the abridged version to support their individual interrogation and analysis of the questionnaire responses. Figure A-3 shows the database schema.

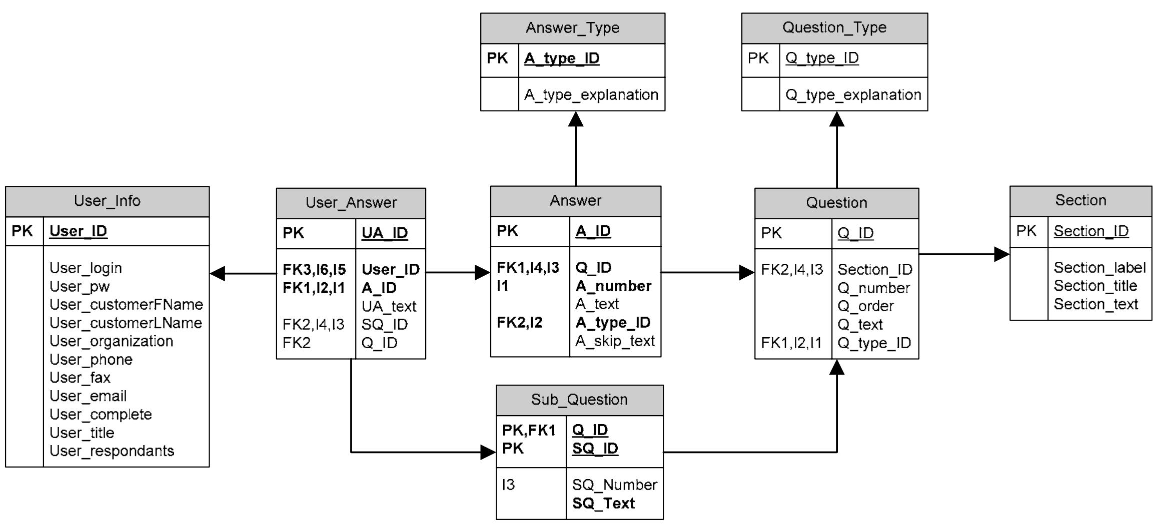

Figure A-3 — RTBPTF Questionnaire Database Schema

Appendix B
Survey Participation

The Real-Time Tools Survey was designed to collect information from NERC registered RCs, TOPs, BAs, and other interested (but unregistered) operating entities who use real-time tools to monitor or analyze the reliability of the bulk electric system. RTBPTF invited representatives from each entity listed in the NERC Transmission System Information Network (TSIN) database to participate in the survey. A total of 59 entities (registered and unregistered) requested access to the survey and completed at least one section. Entities that did not complete at least one section were excluded from the analysis. The survey participants included all 17 North American RCs, 39 TOPs, and 3 BAs (who are not also TOPs or RCs).

Several entities that completed the survey perform more than one NERC function. For example, some entities may serve as both a TOP and a BA; others [e.g., the Electric Reliability Council of Texas] may even serve as RC, TOP, <u>and</u> BA. RTBPTF contacted these "multi-function" entities to clarify their status, and each was reclassified, for purposes of the survey, according to its highest-level function. RCs are considered the highest-level entities, and balancing authorities are considered the lowest-level entities, with TOPs in the middle. Thus, for example, an entity registered as a TOP and an RC would be classified as an RC for the survey analysis; an entity registered as a BA and a TOP would be classified as a TOP. This classification protocol was used to ensure that the information submitted by each participant was not counted more than once in the final analysis of survey results.

Some entities' situations posed classification challenges. One RC contracts some or all of its real-time reliability tools through a registered TOP. The survey response submitted by the TOP for this entity included the RC's response. Therefore, after contacting both entities, the task force reclassified the TOP's response as an RC response. One entity that responded to the survey was not a NERC registered RC, TOP, or BA. After the task force contacted this entity, its response was classified in the category that most closely corresponded to its role.

The entities that participated in the survey are listed below according to the function assigned to each for survey analysis purposes. Figure B-1 shows a map of the geographical footprint of RCs that participated in the survey, and Table B-1 lists the RCs. Figure B-2 shows the footprint of the TOPs and BAs that participated in the survey, and Tables B-2 and B-3, respectively, list the TOPs and BAs.

Reliability Coordinators	
1	Bonneville Power Administration (BPAT) for Pacific Northwest Security Coordinator
2	Southern Company Services, Inc. (SOCO) for Southern Subregion
3	Entergy Services, Inc. (EES)
4	Energy Reliability Council of Texas Independent System Operator (ERCOT)
5	Florida Reliability Coordinating Council (FPL / FRCC)
6	Hydro-Quebec TransEnergie (HQT)
7	The Independent Electricity System Operator (IMO)
8	Independent System Operator New England (ISNE)
9	New Brunswick System Operator (NBSO)
10	New York Independent System Operator (NYIS)
11	Pennsylvania-New Jersey-Maryland Interconnection (PJM)
12	Duke Energy Corporation (DUK) for VACAR-South
13	California Mexico Reliability Coordinator (CMRC)
14	Midwest Independent System Operator (MISO)
15	Rocky Mountain - Desert Southwest Reliability Coordinator (RDRC)
16	Southwest Power Pool (SWPP)
17	Tennessee Valley Authority (TVA)

Table B-1 — Entities who participated in the Real-time Tools Survey and were classified as RCs

	Transmission Operators
1	Alabama Electric Cooperative, Inc. (AEC)
2	Alberta Electric System Operator (AESO)
3	American Electric Power (AEP) - Central & Southwest (CSWS)
4	Associated Electric Cooperative, Inc. (AECI)
5	Cinergy Corp (CG&E)
6	Cinergy Corp (PSI)
7	Cleco Corporation (CLEC)
8	COMISION FEDERAL DE ELECTRICIDAD (CFE)
9	First Energy (FE)
10	Idaho Power Company
11	International Transmission Company (ITC)
12	Lincoln Electric System (LES)
13	Northern Indiana Public Service Co. (NIPS)
14	NorthWestern Energy (NWMT)
15	Oklahoma Gas & Electric (OKGE)
16	Otter Tail Power Company (OTP)
17	Public Service Company of New Mexico (PNM)
18	Grant County Public Utility District (GCPD)
19	Public Utilities District # 1 of Douglas County (DOPD)
20	Santee Cooper (SC)
21	Saskatchewan (SPC)
22	Sierra Pacific Power Company (SPPC)
23	South Carolina Electric & Gas Company (SCEG)
24	Southern Minnesota Municipal Power Agency (SMP)
25	Southwestern Public Service - Xcel (SPS)
26	Tennessee Valley Authority (TVA)
27	Vectren Energy Delivery of Indiana (VEDI)
28	Westar (WR)
29	Western Area Power Administration - Upper Great Plains Region (WAUW)
30	Allegheny Power (AP)
31	American Electric Power (AEP)
32	American Transmission (ATC)
33	Aquila Inc. (WPEL)

Appendix C
Survey Analysis Methodology

Introduction

Given the breadth and depth of the Real-Time Tools Survey, RTBPTF recognized that reviewing and analyzing the survey responses would be a monumental task. This appendix explains the methodology that the task force developed to summarize and analyze the survey results and to develop recommendations from them.

Individual task force members reviewed and analyzed specific survey sections and prepared the corresponding portions of this report. To process the massive number of data from the survey, the task force used summary reports and database query tools. To ensure consistency and uniformity of individual reviewers' efforts and to produce this final, comprehensive report, the task force created and followed a structured methodology and a checklist of key steps.

The sections below describe the tools; checklist; and underlying criteria, principles, and guidelines that the task force used in analyzing the survey data.

Analysis Tools

RTBPTF members accessed the database of all survey responses on a secure web site hosted by NERC. Lawrence Berkeley National Laboratory (LBNL), which created the survey software, also created summary reports of responses organized by survey section. These reports were posted on the secure web site, so task force members could download them. In addition, LBNL created an on-line tool that enabled task force members to query the responses to any individual question and see a breakdown by respondent type – RC, TOP, and/or BA.

Task force members could also download the entire survey database and create their own custom queries and reports. One task force member created a summary report of the entire database in a text format and shared it with the other members. Other members created and shared database queries, indices, spreadsheets, and tables.

Survey Review Checklist

The task force created a checklist that outlined the "roadmap" for the complex journey from raw survey responses to the material needed to prepare a final report that would fulfill the task force's deliverables requirement. The checklist contained the following steps:

- Download and review the results file for each task force member's assigned section

- Use Question Query Tool to review responses to particular questions by entity type
- Download survey database into Microsoft Access and design custom queries as needed
- Prepare initial, high-level lists of findings
- Identify related questions from other sections to validate/invalidate initial findings
- Review initial findings in relation to the report on minimum requirements and best practices for reliability software presented at 2004 FERC technical conference on Information Technology for Reliability and Markets[2]
- Refine and summarize initial findings
- Develop recommendations for new standards based on summary of findings
- Develop recommendations for operating guidelines based on summary of findings
- Identify areas requiring more analysis based on summary of findings
- Identify examples of excellence based on survey responses and follow-up interviews

Principles for Summarizing Findings

To ensure that they did not stray from RTBPTF's scope, the task force members focused, when summarizing the survey findings, primarily on issues directly related to reliability and situational awareness. Thus, they undertook to address causes of the August 14, 2003 blackout that were related to real-time tools and situational awareness, as identified in the NERC Steering Group Report to BOT[3] and the *Outage Task Force Final Blackout Report*.[4] In addition, RTBPTF members reviewed existing reliability standards to identify the ones containing requirements related to the tools or practices covered in the survey and to determine which standards needed new or revised requirements. After FERC

issued its *Staff Assessment* of NERC's proposed reliability standards,[5] RTBPTF endeavored to address the issues raised in the assessment that were germane to the task force's scope.

In summarizing survey findings, the task force differentiated between the responses of RCs and those of other survey participants where possible and relevant. One reason for breaking out RC responses was to highlight any major differences between the reliability tool use and operating practices of RCs and those of other entities. Another reason was that all 17 RCs responded to the survey, so, in statistical terms, the total population of RCs was represented. However, only about one-third of registered TOPs and BAs (who are not also RCs) participated, so those responses represent non-random samples of the populations of TOPs and BAs.

RTBPTF looked for clear majorities in the responses to questions about tool usage and practices to identify prevalent practices, which help form the rationale for many of the recommendations in this report. The tables and statistics in the technical sections of this report are designed to illustrate how many respondents answered specific questions in particular ways. In writing their analyses, task force members attempted to summarize the conclusion supported by each set of statistics and tables.

Other guiding principles for summarizing survey results included: 1) quoting survey respondents' comments when quotes are appropriate and help make a point, 2) not self-censoring findings and recommendations because of anticipated controversies, 3) identifying areas in which most respondents seem to be doing well, 4) identifying areas where the industry in general needs improvement, and 5) identifying important issues where the data are insufficient to properly evaluate a tool or practice or are too inconclusive to justify action.

Criteria for RTBPTF Recommendations

RTBPTF's recommendations in this report are based upon several criteria that the task force established to determine which of the following four options were justified by the survey findings for each topic: 1) recommendation for new reliability standards (or revisions to existing standards), 2) recommendation for operating guidelines, 3) identification of areas requiring more analysis, or 4) identification of examples of excellence. These four options were derived from the task force's understanding of its assigned responsibilities as explained in the discussion of "best practices" in the Introduction to this report. The specific criteria for each option are described below.

---

[5] Federal Energy Regulatory Commission (FERC). 2006. *Staff Preliminary Assessment of the North American Electric Reliability Corporation's Proposed Mandatory Reliability Standards*. www.ferc.gov/indus-act/reliability/standards.asp.

Basis for Recommending New or Revised Reliability Standards

1. Recommendations for revisions to existing standards must support or provide clarification to the existing standards.
2. Recommendations for new reliability standards must pertain to tools or practices that materially affect bulk electric system reliability.
3. Recommended requirements must be measurable.
4. All recommendations must support the NERC Reliability and Market Interface Principles.[6]
5. Recommendations must be made by consensus of RTBPTF's active members.
6. Recommendations should support the needs and gaps identified by the NERC and Outage Task Force *Blackout Reports* and the FERC *Staff Assessment* of NERC standards.

Basis for Recommending Operating Guidelines

RTBPTF's criteria for recommending operating guidelines are based to some extent on the criteria for establishing "Best Practices" identified by the NERC Operating Committee's Best Practices Task Force in its report,[7] which was approved by the NERC Operating Committee in December 2005. A key recommendation of the Best Practices Task Force was that "Operating Guidelines" and "Examples of Excellence" should be established in lieu of "Best Practices." RTBPTF's criteria for recommending practices to be documented as operating guidelines are as follows:

1. Practice must be prevalent within the industry (employed by >50 percent of survey respondents).
2. Practice must support an existing or proposed standard.
3. Practice must be proven to be effective.
4. Practice cannot be considered to be essential to maintaining bulk electric system reliability (because operating guidelines are not mandatory).
5. Practice must be feasible to implement.
6. Practice must be applicable over a wide range of organizations that perform the practice for which the operating guideline applies.

---

[6] ftp://ftp.nerc.com/pub/sys/all_updl/tsc/stf/ReliabilityandMarketInterfacePrinciples.pdf

[7] *Best Practices Task Force Report: Discussions, Conclusions, and Recommendations*. 2005. December 1.

Basis for Identifying Areas Requiring More Analysis

1. Were the survey results inconclusive?
2. Was the tool or practice not adequately addressed in the survey?
3. Is the topic a significant “hole” in the overall reliability “fabric?”

Basis for Identifying an Example of Excellence

Because the Real-Time Tools Survey was completed prior to the Best Practices Task Force final report mentioned above, which recommended that "Operating Guidelines" and “Examples of Excellence" be established in lieu of "Best Practices," the survey results included “Best Practices” that were self-nominated by survey respondents. RTBPTF reviewed the nominations and attempted to identify the practices related to tools and/or operating practices that go beyond the minimum requirements of existing standards and are unique to individual organizations but may not be applicable throughout the industry.

The criteria used to differentiate the self-nominated practices and develop the examples listed in this section of the report are as follows:

1. Example must be nominated by either the individual entity or a task force member, and must be approved by both.
2. Example can be assumed to function as stated, i.e., task force will not verify functionality.
3. Recommendations that do not demonstrate an understanding of the tool or a practice discussed in the report will not be considered.
4. Example must be an existing practice, not a desired or planned practice for which empirical results have not been established.
5. Example must be considered not to be commonly used by the majority of the industry; however, the task force will not conduct a side-by-side comparison of each respondent’s practices.
6. Example must be an outstanding practice that the industry could strive to achieve.
7. From survey responses, the task force identified self-nominated “best practices.”
8. Identified best practices were correlated with examples of excellence from NERC readiness audits.

In lieu of conducting face-to-face interviews with the respondents who self-nominated an example of excellence, the task force conducted follow-up email surveys with those respondents. The follow-up surveys consisted of the following questions:

1. Have User fully describe the tool/practice:
    a. What does it do?

b. Who uses it?
c. What are the inputs/outputs?
d. What is the user interface?
e. What is/was the alternative practice?

2. How does it enhance reliability and/or situational awareness?
3. Which reliability standard(s) does it help meet or exceed?
4. What did it take to implement?
5. What does it take to maintain?

Appendix D
Real-Time Tools Survey

The RTBPTF Real-Time Tools Survey questionnaire and the survey results are available at http://www.nerc.com/~filez/rtbptf.html.

Appendix E
Examples of Excellence

Introduction

Real-Time Tools Survey participants were given an opportunity to document a potential example of excellence. RTBPTF reviewed each proposed example of excellence and in some instances requested additional information before deciding to include it in this report. Appendix E presents all the examples of excellence that RTBPTF recommends to the industry for further consideration.

A detailed description of each example of excellence follows, with cross reference to the section of the report in which the example is identified.

Examples of Excellence

EOE-1

Reference — Section 1.1, Telemetry Data
Submitted by — Northeast Power Coordinating Council (NPCC)

Description

RTBPTF has recommended modifications to existing NERC reliability standards with regard to monitoring of bulk electric system elements/parameters. Section 1.1, Telemetry Data, addresses the need to clarify the definition of the term “bulk electric system.” RTBPTF recommends that RCs produce a document called the Bulk Electric System Elements List to specify the elements/parameters monitored within a reliability area. RTBPTF cites the Northeast Power Coordinating Council (NPCC) as an example of excellence in establishing and facilitating a process/methodology for classifying bulk power system elements within the NPCC RRO. NPCC’s “Criteria for Classification of Bulk Power System Elements (A-10)” document (http://www.npcc.org/document/abc.cfm) is used to identify elements to which NPCC bulk power system criteria apply. NPCC’s A-10 Criteria document recognizes that each RC area has an existing list of bulk power system elements.

RTBPTF believes that NPCC’s methodology for classifying bulk electric system elements qualifies as an example of excellence and exemplifies the RTBPTF recommendation of producing a Bulk Electric System Elements List.

Examples of Excellence

EOE-2

Reference — Section 1.2, ICCP-Specific Data
Submitted by — ISO New England

Description

ISO New England and its transmission owners have implemented an automated trouble-tracking system that includes processes and procedures for reporting, notification, tracking, resolution, and escalation of ICCP data problems.

General Information

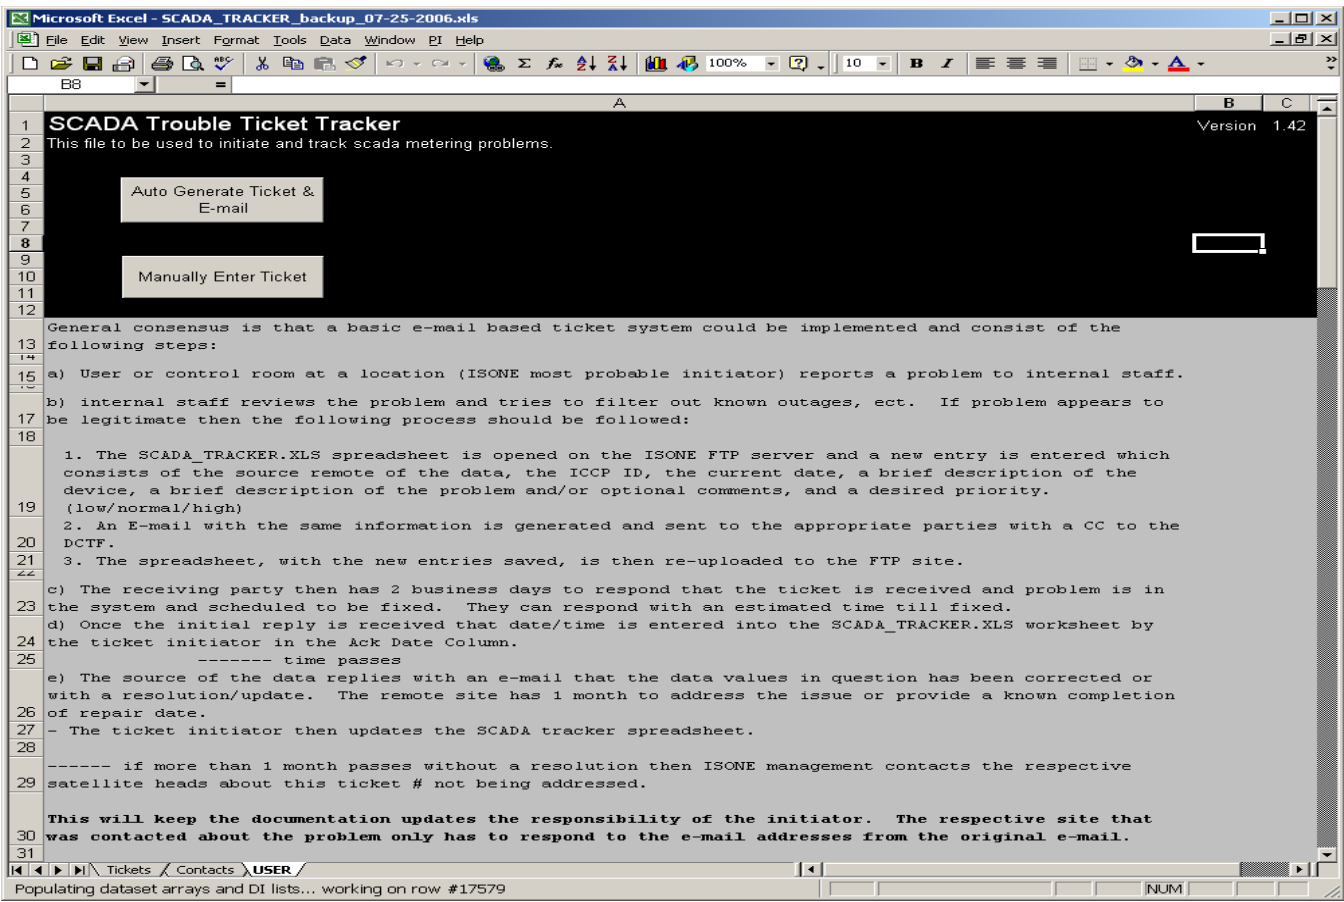
- Tool/Practice Name
  - SCADA TRACKER, a set of procedures, and an Excel spreadsheet system for reporting and tracking the resolution of SCADA data problems related to the New England ICCP network
- Organization Name
  - ISO New England
- NERC Registration (e.g., reliability coordinator)
  - reliability coordinator
  - balancing authority
  - transmission operator
- Contact Name
  - Brock Nubile
- Contact's Official Title
  - Lead EMS Support Specialist
- Contact's Telephone Number
  - 413-540-4210
- Contact's E-mail Address
  - bnubile@iso-ne.com

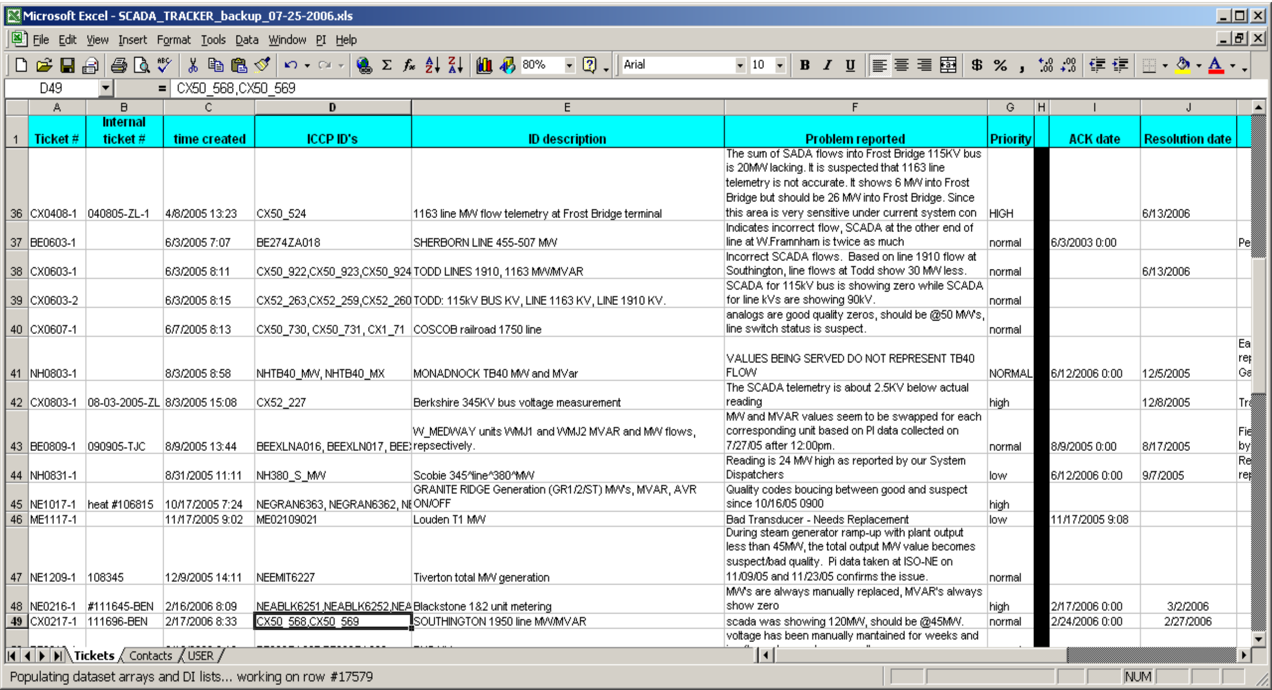
Description of the Tool/Practice

- What does it do?
  - Provides a standard format and procedures for creating trouble tickets related to ICCP SCADA data problems. The Excel spreadsheet contains the procedures, the tracking log, and a set of macros that automatically creates an e-mail message of the ticket to be sent to the appropriate transmission owner/SCADA site. This provides a mechanism for all sites on the network to report data problems that affect all sites on the network. It also provides a log to track resolution of all problems.
- Who uses it?
  - ISO and transmission owner/SCADA EMS support staff
- What are the inputs?

- o Detailed Information about the ICCP data ID with a description of the problem — ICCP ID, data owner, date, problem with the data, and priority rating

- What are the outputs?
  - o Spreadsheet tracking sheet, automatic e-mail message generated
- What is the user interface?
  - o Microsoft Excel spreadsheet; see screenshots below.
- What is/was the alternative practice?
  - o Individual e-mails or phone calls to IT personnel at each site





Microsoft Excel - SCADA_TRACKER_backup_07-25-2006.xls

Tickets / Contacts / USER

Populating dataset arrays and DI lists... working on row #17579

Reliability/Situational Awareness

- How does it enhance reliability and/or situational awareness?
  - o Improves repair times for SCADA data by getting the appropriate information to the correct staff in a timely fashion
  - o Broadcasts trouble report to all transmission owner sites so all parties are aware of the problem
  - o Provides a tracking mechanism to identify the current status of a data problem and helps identify data values with repeated problem
- Which reliability standard(s) does it help meet or exceed?
  - o IRO-003
  - o IRO-005
  - o TOP-006
  - o TOP-005
  - o COM-001

Support and Maintenance Issues

- What did it take to implement?
  - o Group agreement to parameters and procedures, appropriate contact lists developed, minor macro programming within Excel
- What does it take to maintain?
  - o Enhancements to tool made upon request and review of ISO-NE's Data Communications Task Force
  - o Each submitter must update log with acknowledgment and resolution date

Examples of Excellence

EOE-3

Reference — Section 1.2, ICCP-Specific Data

Submitted by — ISO New England

Description

ISO New England and its transmission owners have implemented an automated monitoring system that periodically compares data set time stamps to detect and alarm any data sets that have stopped updating for any reason.

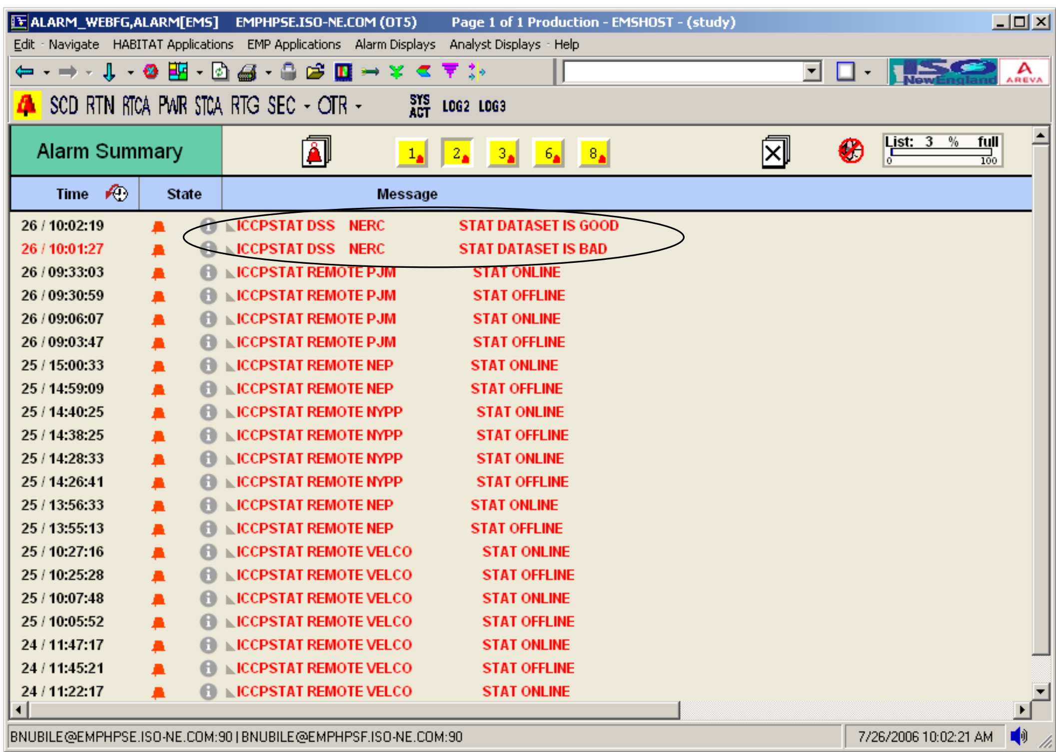
General Information

- Tool/Practice Name
  - DSMON (Data Set Monitor), an in-house designed and written PERL program that monitors all inbound and outbound ICCP server data sets on our vendor-based ICCP servers to confirm that they are transferring data
- Organization Name
  - ISO New England
- NERC Registration (e.g., reliability coordinator)
  - reliability coordinator
  - balancing authority
  - transmission operator
- Contact Name
  - Brock Nubile
- Contact's Official Title
  - Lead EMS Support Specialist
- Contact's Telephone Number
  - 413-540-4210
- Contact's E-mail Address
  - bnubile@iso-ne.com

Description of the Tool/Practice

- What does it do?
  - Every 90 seconds the program dumps a list of all ICCP database data sets and compares the last transfer set time to real time while accounting for the data-set transfer parameters. If delta exceeds a threshold, an alarm is issued to the operators on the EMS. This program detects and alarms any data sets that are interrupted because of:
    - Data-base modeling errors when remote sites perform updates (most common)
    - ICCP application software bugs, memory leaks, or extended run times
    - Severe network problems in which ICCP associations cycle frequently (a failed data set is usually the first symptom)

- Who uses it?
  - o Dispatchers and IT support staff
- What are the inputs?
  - o Vendor-based ICCP database, time-synchronized local ICCP server clock, user-entered run-time periodicity
- What are the outputs?
  - o GOOD/BAD status for each ICCP remote's data sets in the form of an ICCP server log file, vendor-based ICCP server data-base values, EMS-based operator alarms
- What is the user interface?
  - o Native EMS-based alarms
- What is/was the alternative practice?
  - o No alternative; this type of monitoring and alarming not offered by the vendor



Reliability/Situational Awareness

- How does it enhance reliability and/or situational awareness?
  - o Alerts operators and IT staff that large portions of data are not updating even though ICCPLINK is still connected and "UP"
  - o Allows IT staff to pursue correcting problem either locally or remotely
- Which reliability standard(s) does it help meet or exceed?
  - o IRO-003

    - IRO-005
    - TOP-005
    - TOP-006
    - COM-001

Support and Maintenance Issues

- What did it take to implement?
    - PERL programming, data-base additions on ICCP and EMS system, training for operators and support staff to respond to the new alarm
- What does it take to maintain?
    - No special maintenance required

Examples of Excellence

EOE-4

Reference — Section 2.2, Visualization Techniques
Submitted by — Northeast Power Coordinating Council (NPCC)

Description

Tool/Practice Name:	Facilitated Transaction Checkout (FTC)
NERC Registration:	Reliability Coordinator
Contact Name:	John M. Simonelli
Contact's Official Title:	Manager Operations Support Services
Contact's Telephone Number:	(413)535-4157

Overview

Historically, the accuracy associated with transaction checkout between those entities tasked with maintaining reliability has been an important industry issue as recognized by both the NERC Operating Committee and its Interchange Subcommittee. In recognition of the reliability concerns associated with transaction checkout and findings from the August 2003 Blackout, elected to undertake a region-wide effort towards improving transaction accuracy.

The NPCC FTC is a tool implemented by all balancing authorities within the NPCC region. PJM expects to implement FTC in the near future, and MISO expects to implement FTC during the fourth quarter of 2006. The tool is a message structure that enables neighboring reliability entities to query each other's transaction stacks and perform an automated comparison prior to performing verbal checkout. This is accomplished through programmatic data exchange using a standard set of protocols agreed to by the NPCC reliability entities. Because the tool is the communication behind the display, the results can be seamlessly integrated into existing EMS applications. The FTC process provides for the data to be easily integrated into existing displays to meet the unique needs of the different balancing authority operators. FTC does not require third-party intervention or support. The current real-time transaction checkout implementation focuses on transactions between entities using the required NERC e-tag as a common identifier. With slight variations to the standard message structure, the tool can and, in some current instances, is being used for Day Ahead/Day Prior transaction verification, after the fact schedule reconciliation, actual tie information and metered tie flow information for inadvertent checkout.

Detailed Description

Transaction Checkout is a common term for an inter-regional business process employed by neighboring BA operators in the northeast. During the Transaction Checkout process, neighboring BAs communicate in an effort to reconcile the pending net interchange between the individual BAs. The primary objective of the Transaction Checkout process is to reach agreement on a net interchange between BAs as well as the underlying list of individual transactions for the next hour. These transactions may be derived under the auspices of full financial markets or under the traditional physical bi-lateral systems. In either case, operators must cross-reference the transactions scheduled separately by each BA to ensure that for each transaction scheduled out of a given BA, there is a corresponding transaction scheduled into the neighboring BA.

For the majority of the industry, this is currently a manual business process accomplished via telephone communication by BA operators. Moreover, each operator has extremely limited (if any) visibility of other BA transactions. Cycling through lists of transactions and cross-referencing them with the neighboring BAs (ensuring that both sides have the same information) is a lengthy and labor-intensive process. Since the operator of one BA does not have any visibility into the other BA's transaction stack, the operator must review each transaction to ensure that it matches the transactions expected in the neighboring BA. Currently, operators must repeat this tedious and inefficient process every hour, 24 hours per day, 7 days per week. Moreover, with the recent efforts to reduce bidding and scheduling to 15-minute intervals, the current process may prove unsustainable.

Facilitated Transaction Checkout (FTC) is accomplished through programmatic data exchange using a standard set of protocols agreed to by the NPCC balancing authorities (BA). Each BA is responsible for providing a "service" that allows other BAs to programmatically request and receive transaction data in preparation for checkout procedures. It is important to point out that there is no standard FTC application or user interface. Each BA has the flexibility to incorporate the functionality into their existing BA tools as each sees fit.

The NPCC FTC solution provides tangible efficiency gains in the transaction checkout process. Advancing this solution from a concept to implementation required mutual cooperation and collaboration from neighboring Balancing Authorities in the northeast. Continued collaboration among NPCC members and its neighbors, PJM and MISO, was vitally important to collectively define, develop, and implement a robust FTC solution.

The proposed FTC solution is not intended to fully automate the process of checkout, nor is it aimed at eliminating the critical human function of the operator. Instead, it is designed to assist system operators by equipping them with the most complete, accurate and timely data possible. The purpose is to facilitate the checkout process such that it can be accomplished in less time and with greater accuracy. The fundamental high-level business process of reviewing transactions between BAs will remain the same; the FTC solution simply makes it easier to execute.

Looking beyond the implementation of FTC in the northeast, an additional direct and tangible benefit of the FTC effort has been programmatic flexibility. The technology developed to support FTC is now serving as the foundation in the development of several other NPCC-wide applications, such as after the fact Inadvertent Accounting and real-time tracking of Shared Activated Reserves. NPCC's development of new, automated "wide-area" tools continues to improve operator efficiency and overall system reliability.

Examples of Excellence

EOE-5
Reference — Section 2.2, Visualization Techniques
Submitted by — Southwest Power Pool (SPP)

Description

Tool/Practice Name:	PowerWorld Retriever
NERC Registration:	Reliability Coordinator
Contact Name:	Kevin Bates
Contact's Official Title:	EMS Engineer
Contact's Telephone Number:	(501)614-3288
Contact's E-mail Address:	kbates@spp.org

Overview

Southwest Power Pool utilizes PowerWorld Retriever to provide a system overview as well as alarm using pie charts and flashing lines. The contouring of voltage, state estimator versus SCADA, generation MW and Mvar availability has proven to be useful in reliability coordination as well as system performance from a technical staff perspective.

PowerWorld Retriever provides a geographical overview of the SPP Reliability system and its neighboring areas. Visualization effects include:

- Arrows depict direction and magnitude of line flow
- "Blinking" lines indicate real-time out-of-service elements
- Pie charts alarm for real-time overloads
- Voltage is contoured

Detailed Description

RCs use PowerWorld Retriever as a situational awareness tool in real-time operations as well as training situations. EMS engineers have also used PowerWorld Retriever for contouring differences between SCADA and the state estimator. Since the PowerWorld Retriever model is derived from the EMS model, PowerWorld Retriever has also been used for model verification.

The PowerWorld Retriever model is constructed using the EMS NETMOM model exported via the EMS modeling tool, Genesys. Programs residing on the EMS export SCADA data every 30 seconds and state estimator data every 1 minute from the EMS to text files. Because real-time status for elements is not available from all sources via ICCP, these elements (lines, transformers, generators) have real-time status points defined using real-time status of associated breakers and switches. These points and analogs are placed in flat text files along with a unique alias that identifies a value in the PowerWorld Retriever model. Configuration files loaded to PowerWorld Retriever upon initialization include subscriptions that provide the “links” between these aliases and the PowerWorld Retriever model data fields. These text files can be generated from any EMS system (production, backup, development, etc.), so PowerWorld Retriever can be utilized in training scenarios as well.

No data outputs are generated by PowerWorld Retriever other than update logs. The data inputs to the model are displayed on associated one-lines which may be geographic or schematic. The aforementioned features (blinking lines, line flow arrows, etc.) are displayed on one-lines that are associated with the underlying model. The text file inputs can be configured to link to any EMS system, therefore resulting in displays showing data from systems used for production, training, or testing.

The interface is typical pull-down menus and toolbars. The most common features used by RCs include navigation tools such as zoom, pan, find, etc. Because of the vast options available, saved views are used to easily navigate between desired displayed data on one-lines. These views have position and layers turned on/off so users are one click from desired views. Case Information tables provide model information and options for sorting, filtering, and exporting. Some substation one-lines are available.

All data displayed in PowerWorld Retriever are available using EMS displays. They are not depicted in a geographic overview but rather a bus/branch or tabular list. With this tool, RCs are made aware of voltage conditions, real-time flows, and outages for the SPP Region and adjacent regions, which enhances their situational awareness. PowerWorld Retriever helps SPP meet Standard IRO-003-0 by providing a wide-area view of the SPP RC Area and the areas of neighboring RCs.

PowerWorld Corporation was contracted to develop the initial model and overview one-line. SPP and PowerWorld staff integrated an export of the SPP EMS model to the PowerWorld Retriever model structure. Also developed with cooperation of PowerWorld staff were alias and subscription formats used in linking data from the EMS to the PowerWorld Retriever model. SPP also developed programs to export SCADA, state estimator, real-time contingency analysis, and outage scheduler data into text files for uploading to PowerWorld Retriever. Some clean-up and customization of the overview one-line was performed as well as of the view definitions.

Maintenance is performed with each upload of a new EMS model or as needed for modeling corrections. Text files with pertinent modeling information are exported using Genesys. Because PowerWorld Retriever's model structure uses bus numbers that do not correlate with a bus number from the EMS model, a Microsoft Access database is used to maintain consistency between models. This prevents renumbering of one-lines during bulk uploads of a new model. Only new or deleted devices need addressed on associated one-lines. This database also allows for export of aliases and subscriptions used for compiling configuration files used by PowerWorld Retriever.

Description

Tool/Practice Name: Wide-Area Overview
NERC Registration: Reliability Coordinator

Overview

MISO implemented an expansive wide-area overview display with underlying BA and one-line displays. MISO also incorporated the following into its visualization tools:

- A flowgate monitoring tool that uses LODFs calculated every 10 seconds. This display also includes a provision for dynamic ratings or operating guides.
- A set of reactive monitoring display "delta" tools that visualize sudden changes in generator output or transmission facility flow.

Examples of Excellence

EOE-7
Reference — Section 2.2, Visualization Techniques
Submitted by — American Transmission Company

Description

Tool/Practice Name:	Wide-Area Overview
NERC Registration:	Reliability Coordinator

Overview

ATC utilizes an application that interfaces directly with its EMS to provide system operators with a dynamic wide-area overview of ATC's network topology as well as state estimation of the neighboring systems. The one-line display (wide-area overview representation) is created automatically from the data within the network model (internal and external). When new equipment is added, the wide-area overview display automatically updates. The wide-area overview provides the operator with actual flows, indications of open lines, and visual indication for lines approaching thermal limits. ATC's operators can dynamically select what is displayed, zoom in or out, and pan across the system. In addition to displaying a wide-area overview, system operators can filter, sort, and query the data to better analyze the power system.

EOE-8

Reference — Section 2.5, State Estimator
Submitted by — Midwest ISO

Description

Tool/Practice Name: State Estimator
NERC Registration: Reliability Coordinator

Overview

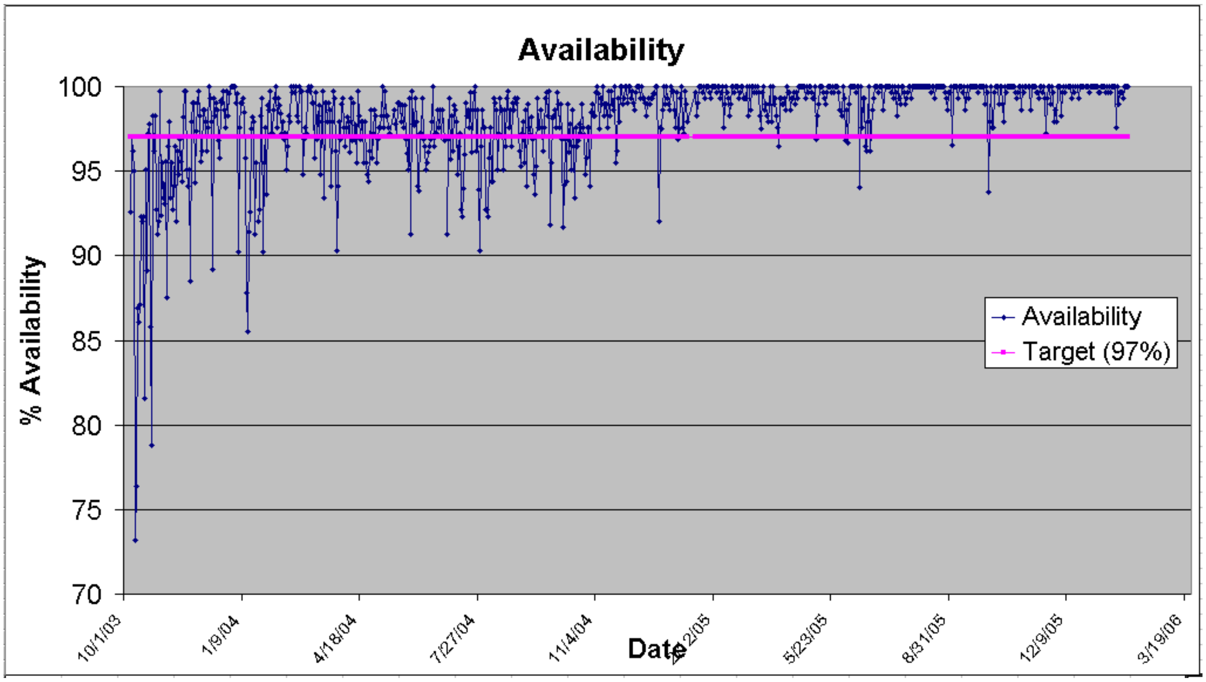
MISO has developed a state estimator solution summary spreadsheet that is used to track solution availability and solution-quality metrics such as solution mismatch, status, convergence, and error tracking for select branch flows, bus voltages, and tie-line flows.

Detailed Description

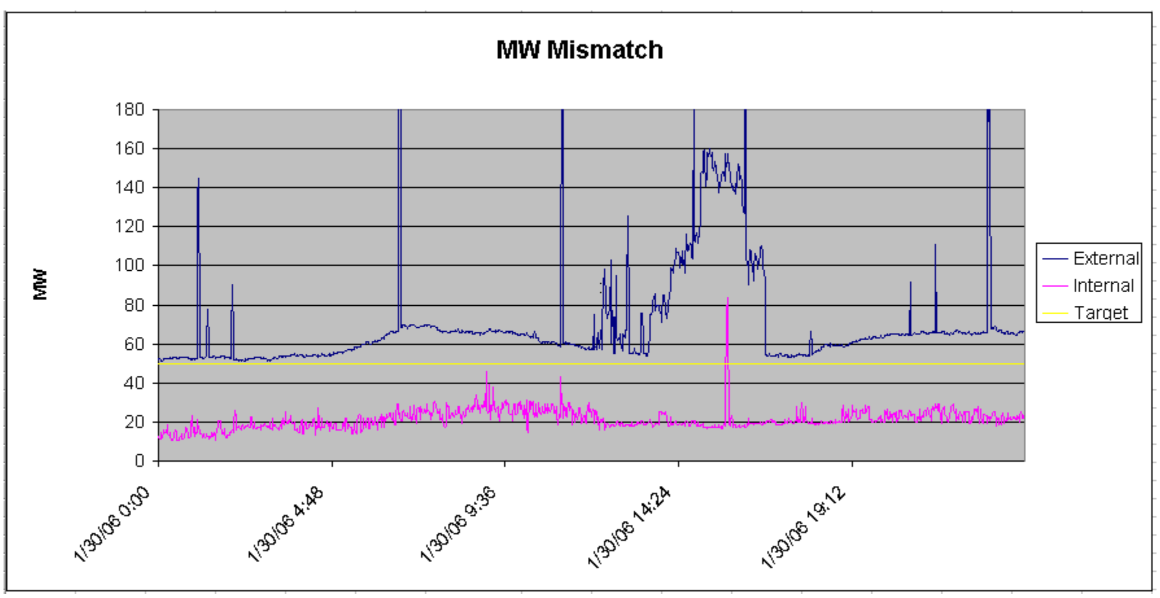
The “home page” of the summary is shown below and includes explanations of what each metric represents.

SE Solution Summary	**01-30-2006** **12:00:00 AM - 11:59:59 PM** Import Data Into Spreadsheet	
State Estimator Metrics Plots	**Plot Explanation**	
State Estimator Availability	**MISO and Transmission Owners require 97% availability. This metric describes the number of 5 minute periods in a day that had a state estimator solution. In a day there exists 288 5 minute periods, to reach 97% availability MISO needs to have state estimator solutions for 280 or more of those periods.**	SE Availability Plot
State Estimator Solution Mismatch	**MISO and Transmission Owners require < 50 MW mismatch for all companies within the MISO footprint. The mismatch data reported here illustrates solution mismatch for both internal and external companies.**	SE MW Mismatch Plot
State Estimator Solution Status	**Illustrates the solution status for each 5 minute period over a 24 hour period. A point of "1" indicates a valid solution period. A point of "0" indicates that no valid solution occurred during that five minute period.**	SE Solution Status Plot
State Estimator Voltage Convergence	**MISO tracks the state estimator voltage convergence on a solution basis. MISO and the Transmission Owners require the state estimator to run with voltage and/or angle convergence tolerances of 0.002, and maximum MW mismatch of 50 MW.**	Voltage Convergence
50 Flowgate, 10 Tie Line, 30 Bus Metrics	**MISO monitors a list of 50 flowgates, 10 external tie lines, and 30 critical bus voltages. These plots illustrate the % error of the solved value compared to the measured**	50 Flowgate, 10 Tie Line, 30 Bus Metrics

The SE availability plot is shown below. It reveals a dramatic increase in the availability of the state estimator as MISO made preparations for the opening of the market. Market applications depend on accurate and highly available solutions from the state estimator to support locational marginal pricing and congestion management.



The MW mismatch plot shown below illustrates how well the total mismatch for companies within the MISO footprint is kept within the target value.



The availability and solution quality metrics illustrated above as well as others that MISO has developed are excellent examples of the types of state-estimator performance metrics that should be monitored as part of the pilot program recommended above. MISO has clearly demonstrated that it is desirable and practical to develop such metrics.

EOE-9
Reference — Section 2.6, Contingency Analysis
Submitted by — Entergy Corporation

Description

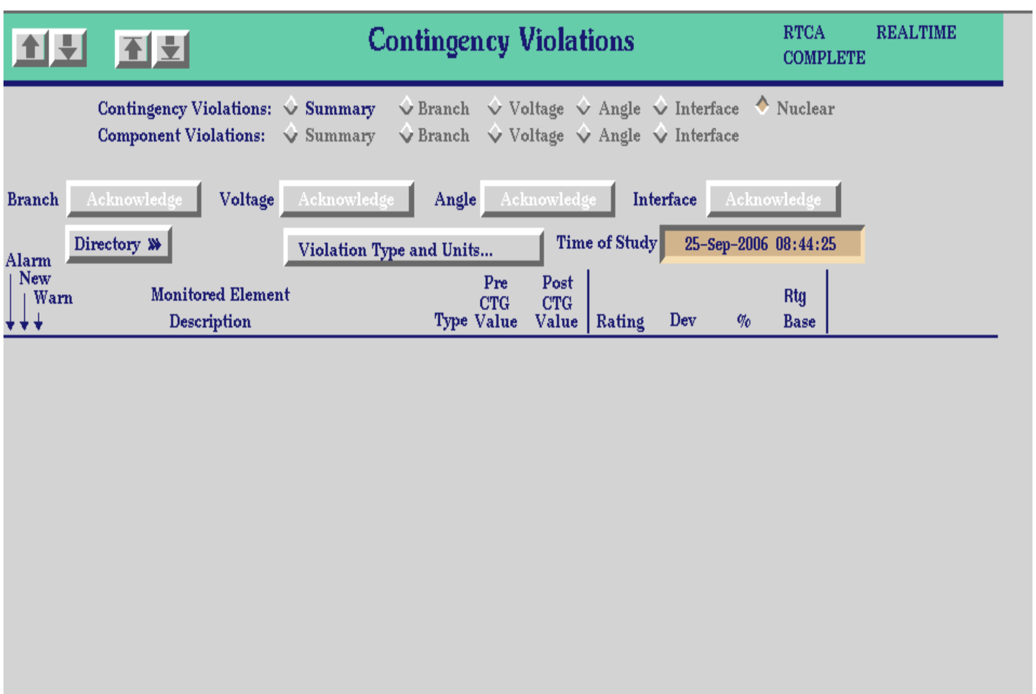
Tool/Practice Name	Utilization of RTCA in Nuclear Offsite Power Monitoring
NERC Registration	Reliability Coordinator, Transmission Operator, Balancing Authority

Overview

Entergy has a real-time contingency analysis application that accurately simulates the effects of loss of a nuclear power plant on switchyard voltage.

Detailed Description

The loss of a nuclear power plant results in the station service load being completely fed by offsite power. To simulate these events accurately, Entergy modified the contingency definitions to add plant load in the event of NPP trip. The real-time contingency analysis at Entergy's control center simulates approximately 1,700 contingencies. To isolate the violations related to NPP offsite power, Entergy also created a separate display that only shows the NPP violations. The following screenshot shows the customized display.



Entergy also developed detailed procedures and operating guides for reporting and acting on NPP offsite power violations. The procedures are summarized below:

Steps to Responding to Violations

Steps 1–3 should be performed within 30 minutes.

1. Verify the validity of the Real-Time Alarm or Post-Contingent Violation.
   a. It is extremely important that all violations are validated prior to continuing with this process.
2. Create State Estimator (RTNET) Save Case to document the violation. The case name should be: “Nuclear_Violation_mm_dd_yyyy_hh_mm”

3. Check the state of the transmission grid for a possible mitigation plan.
   a. Determine if there are any capacitors or reactors in the area that would help relieve the violation.
   b. Determine if there are any transmission equipment outages in the area that are having an impact on the violation.
   c. Determine if there are any generators (Other than the Nuclear Generator) that can be utilized to help relieve the violation. ***The Nuclear Generator can be called to assist with relieving HIGH Voltage, but should NOT be utilized to relieve LOW Voltage.
4. Develop and execute the mitigation plan. This mitigation plan should be capable of relieving the violation without having a negative affect on the reliability of the transmission system. Steps 1-3 must be completed within 30 minutes following the violation.
5. Report the violation to the respective nuclear plant using the following form (Regardless of whether or not the mitigation plan corrected the violation).

   This form should be faxed to the respective nuclear plant and followed up with a phone call to verify the receipt of the fax.

6. If the violation was NOT corrected, proceed to step 7. If the violation WAS corrected no further action will be required. However, be prepared to answer questions from nuclear personnel regarding the violation.

   Fax updated Online Notification Form to the Respective Nuclear Plants and follow up with a phone call to verify the receipt of the fax.

7. If the mitigation plan fails to relieve the violation within 30 minutes or a mitigation plan could not be determined within 30 minutes, contact the on-call support personnel, on-call Duty Chief and the Reliability Coordinator to make them aware of the situation.

   Fax updated Online Notification Form to the Respective Nuclear Plants and follow up with a phone call to verify the receipt of the fax.

8. **Nuclear Conference Call:** If a violation still exists, the nuclear plant will set up a conference call with nuclear and transmission. Once the system operation center (SOC) has been notified of the conference call time by nuclear, the SOC Shift Supervisor will be responsible for notifying the following transmission personnel of the conference call. ***To notify this group you will need to send a page to the "Nuclear Notification" Group using the following text: ***Name, Phone Number***. Nuclear Offsite Voltage Notification made on ***mm/dd/yyyy*** at ***HH:MM***. Conference call will begin at ***HH:MM***. Phone Number: **###-###-####**. Access Number: **#####**

    - Transmission Operational Planning Representative
    - SOC Duty Chief
    - Operations Director
    - System Security - Manager
    - Reliability Coordinator
    - Reliability Coordinator Support
    - TOC Manager for area of discussion

9. Following the conference call, the SOC Shift Supervisor will be responsible for the execution of any additional transmission actions as well as continuing to monitor the violation.

   Fax updated Online Notification Form to the Respective Nuclear Plants and follow up with a phone call to verify the receipt of the fax.

10. Once the violation has ended, the SOC Shift Supervisor will be responsible for sending the nuclear plant the completed Nuclear Notification form and notifying all transmission personnel involved of the end of the violation.

    The form should be faxed to the respective nuclear plant and followed up with a phone call to verify the receipt of the fax.

11. Create State Estimator (RTNET) Save Case to document the violation. The case name should be: "Nuclear_Violation_mm_dd_yyyy_hh_mm"

The process also requires operators to monitor availability of real-time contingency analysis and the state estimator. Entergy also established a procedure to notify nuclear power producers in the event of unavailability of real-time contingency analysis or the state Estimator. The procedure is outlined below. These procedures are only applicable for notifying nuclear plants.

Steps to take when the state estimator is unavailable:

1. Document the time that the state estimator became unavailable. Report the unavailability to EMS on call person.
2. Can the state estimator be restored in <1 Hour?

a. **YES:** Continue to monitor on how long the state estimator has been down. If the restoration time exceeds 1 Hour, proceed to step 2b.

b. **NO:**

  i. Contact the on-call Operations representative.

    1. Verify that the Offline Nuclear Monitoring System is available.
    2. Discuss any unplanned system changes that have occurred since the last time Operations ran the nuclear offline study.[8] If changes have occurred, request that Operations rerun the nuclear study to check for any issues.

  ii. Verify that the SOC EMS system is functioning.

    1. **If SOC EMS System is <u>NOT</u> functioning:** Contact each Transmission Operation Center (TOC) that has a nuclear plant within its system and request that it notify the SOC if any low-voltage alarms are received at any substation near the nuclear plant. Proceed to iii.
    2. **If SOC EMS System <u>IS</u> functioning:** Continuing to monitor for any nuclear voltage alarms. Proceed to iii.

  iii. Notify each nuclear plant using the following form.

  This form should be faxed to the respective nuclear plant and followed up with a phone call to verify the receipt of the fax.

3. After the state estimator has retuned to service and the SOC EMS is functioning correctly.

  a. If the nuclear plants were previously contacted in the above step, notify each nuclear plant using the same form as above.

  The form should be faxed to the respective nuclear plant and followed up with a phone call to verify the receipt of the fax.

  b. If the SOC EMS System was not functioning correctly and the TOCs were requested to monitor real-time voltage alarms around the nuclear plants, contact the TOCs and inform them that the SOC EMS System is now functioning correctly.

[8] Entergy has also implemented an offline process to monitor the nuclear power plant offsite power for next day.

EOE-10
Reference — Section 2.7, Critical Facility Loading Assessment
Submitted by — PJM

Description

Tool/Practice Name: Thermal Tracking
NERC Registration: Reliability Coordinator

Overview

The Thermal Tracking (TT) critical facility loading assessment nominated by PJM was originally supplied as a standard part of their EMS vendor software but has been subsequently enhanced by PJM. TT is used to screen for transfer interface violations and a number of potentially serious double-contingency violations. Of particular value is the enhanced capability for this application to advise operators of the generation redispatch options to alleviate reported overloads. This tool also acts as a backup should the first-line security analysis functions abort or otherwise degrade.

Examples of Excellence

EOE-11
Reference — Section 2.9, Study Real-Time Maintenance (SRTM)
Submitted by — PJM

Description

Tool/Practice Name:	Study Real-Time Maintenance
NERC Registration:	Reliability Coordinator

Overview

PJM Regional Transmission Operator (RTOP) can host up to three users of the SRTM function simultaneously in the production EMS environment. The function is typically performed by support staff, not operators. To avoid conflicts, each user of the SRTM function is completely independent of the production real-time system and of any other SRTM users. Each SRTM user interface looks and feels exactly like the production network applications. However, instead of the red window border used to indicate the production real-time system, a green window border is used to clearly distinguish that the user is actually in SRTM mode.

Historical real-time state estimator saved cases are archived automatically every 5 minutes. All non-converged state estimator solutions are archived automatically when they occur. An SRTM user can be initialized from a historical saved case or the current real-time state estimator solution within seconds. All real-time network applications including NTP, CFLA, flowgate distribution factor calculation, state estimator, contingency analysis, and voltage stability are initialized from the saved case or the current real-time solution. All real-time network applications can be run exactly as they were in the real-time production EMS environment; therefore, all problems and results can be reproduced for debugging purposes. An SRTM case can be archived by the user and retrieved at a later time to complete work. An SRTM case can be used to initialize a study power-flow user, in the same manner as from a real-time state estimator case, to simulate the study network applications.

It is important to note that an old case archived from a previous version of the network model may not be compatible with the current version of the network model depending on the number and type of model changes. To avoid this problem, PJM debugs problems as soon as possible after they occur and prior to updating the network model on the production system if possible. If the model has to be updated prior to resolving a problem, the case is used on a non-production EMS system with the previous version of the network model to complete the work. The PJM practice is to debug and resolve all non-converged state estimator solutions, all non-converged contingency analysis solutions, and all non-converged voltage stability solutions using SRTM as quickly as possible.

In addition, any other network application problems identified by PJM staff are debugged and resolved as quickly as possible using SRTM.

SRTM allows PJM to quickly and easily recreate, debug, and resolve network application problems without impacting the real-time network applications and has increased the overall availability of the real-time network applications. The PJM SRTM was provided by the PJM EMS vendor with some customization. Significant initial testing was required to insure that the initialization software was operating correctly to insure that SRTM results exactly matched the production system. The PJM EMS network applications support staff are the primary users of the SRTM. The PJM system operators, reliability engineers and other engineering support staff also use the SRTM. Because SRTM is fully integrated with the production EMS system, it requires little additional maintenance.

Submitted by — PJM

Description

Tool/Practice Name:	Real-time Voltage Stability Application
NERC Registration:	Reliability Coordinator

Overview

PJM is working on an enhanced real-time voltage stability application to provide control actions to avoid collapse and increase stability margins.

Examples of Excellence

EOE-13
Reference — Section 2.14, Other Tools (Current and Operational)
Submitted by — Bonneville Power Administration

Description

Tool/Practice Name:	Congestion Management Application
NERC Registration:	Balancing Authority, Transmission Operator

Overview

The Bonneville Power Administration (BPAT) uses a curtailment wizard in its implementation of a congestion management application. This wizard is an effective and key component of BPAT's congestion management tool for the interties. Schedule adjustments are communicated and coordinated among the affected parties via the e-tag. For the network, BPAT has an "interim" curtailment calculator, which targets specific generation and loads. This curtailment calculator can be used on two of the network flowgates. This is an "in-hour" tool and it works effectively by targeting specific generators and loads. However, it lacks a prospective view of upcoming flows and does not support preventing transmission sales that would further exacerbate the congestion. BPAT is currently planning to integrate e-tag curtailments with these "interim" curtailment calculators while pursuing tools to provide a full capability to manage capacities and congestion on their network.

Examples of Excellence

EOE-14

Reference — Section 2.14, Other Tools (Current and Operational)
Submitted by — FirstEnergy (FE) and MISO

Description

Tool/Practice Name:	Real Power-Voltage Stability Analysis Tool
NERC Registration:	Reliability Coordinator, Transmission Operator

Overview

Excerpted from survey comments by an FE representative:

> An operator must maintain an awareness at all times of where the system is operating relative to all limits. FE, in conjunction with the Midwest Independent Transmission System Operator (MISO), utilizes a real power-voltage (P-V) stability analysis tool that determines system operating limits in three critical areas of the FE transmission system. NERC commended the FE/MISO approach to voltage stability analyses as an Example of Excellence in their November 2, 2005 Reliability Readiness Audit and Improvement Program**.**
>
> P-V analysis is used to determine the health of the system by determining the rate of voltage decay at a system bus as the level of real power changes due to system loads or transfers across the system. The “nose” of the P-V curve represents the maximum real power load that can be served or the amount of power that can be transferred beyond which the rate of voltage decay dramatically increases toward voltage collapse. The difference between the real power quantity being monitored in real time and the real power limit at the nose of the curve is the real power operating margin. The MISO reliability coordinators and FE transmission operators monitor the flow on the three critical interfaces in real time to the lower of the voltage collapse limit, the steady-state voltage limit, and the thermal ratings limit. To provide a sufficient operating margin, MISO and FE apply a ten percent power flow safety margin in the next-day analysis and a five percent margin for the current-day analysis in determining the voltage collapse limit the operators will use. Additional analysis is conducted any time a critical facility in the FE area is out of service. For forced or emergency outages, a MISO operations engineer position is staffed around the clock to perform the analysis.

Examples of Excellence

EOE-15
Reference — Section 3.5, Load-Shed Capability
Submitted by — Dominion Virginia Power

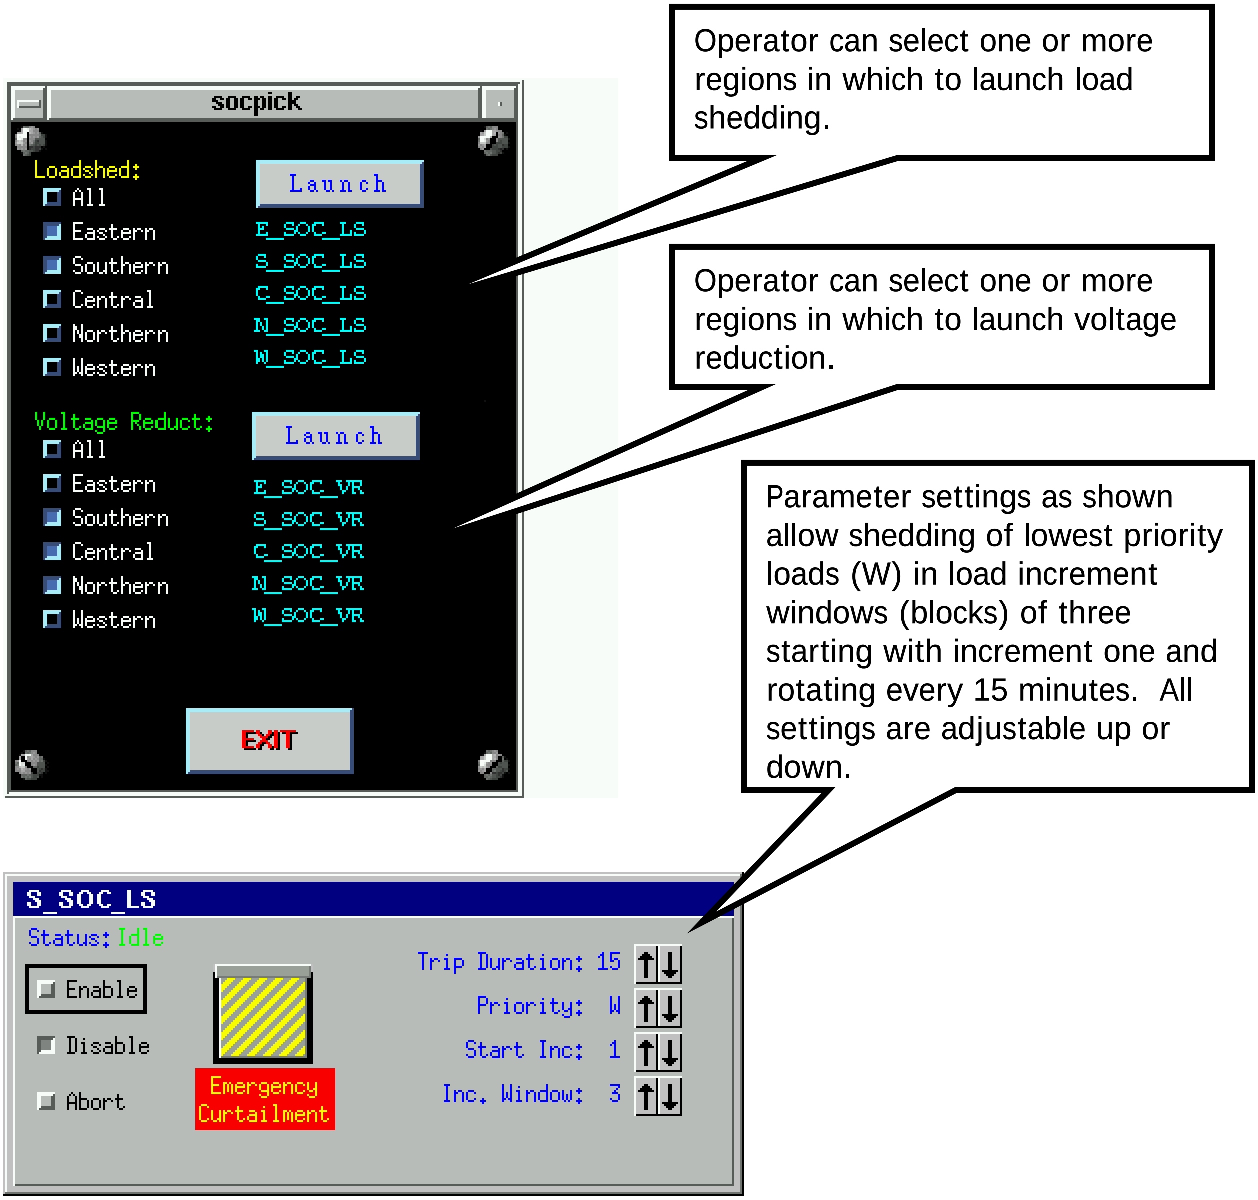
Description

Tool/Practice Name:	Load Shedding/Rotation and Voltage Reduction
NERC Registration:	Transmission Operator

Overview

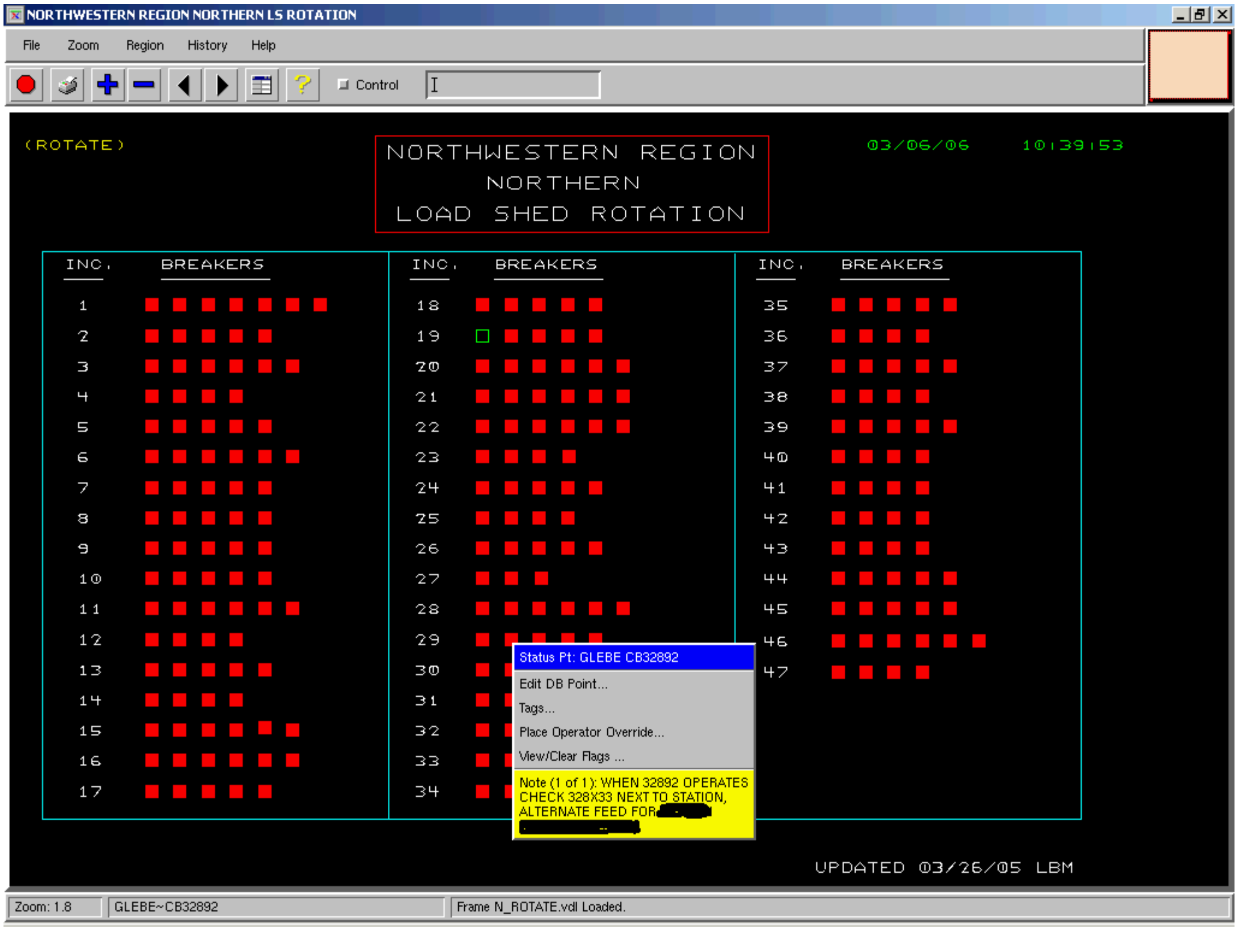
In order to quickly activate the Dominion Virginia Power Load Curtailment Plan, a control application was developed by Dominion to implement load shedding/rotation and voltage reduction. This application runs on the Distribution Management System (DMS), which was developed in house. The application is available to the transmission system operators at the SOC and is also available to the operators at the regional Distribution Operations Centers (DOCs). The program that allows the SOC to implement load curtailment is called SOCpick, and the program that allows the DOC to implement load curtailment is called Loadpick. The main difference between the two programs is the operator interface.

The transmission system operators at the SOC are responsible for implementing load shedding and voltage reduction at the direction of the RC. They can perform this function from their user interface at the SOC or they can request assistance from the regional operators in the three DOCs. The following screen shots show the SOCpick user interface for launching a system-wide or regional load-shed operation or voltage reduction and the user interface for adjusting the load-shed program parameters including trip duration, load priority (W — the lowest, X, Y, or Z — the highest), starting load increment, and load increment window.

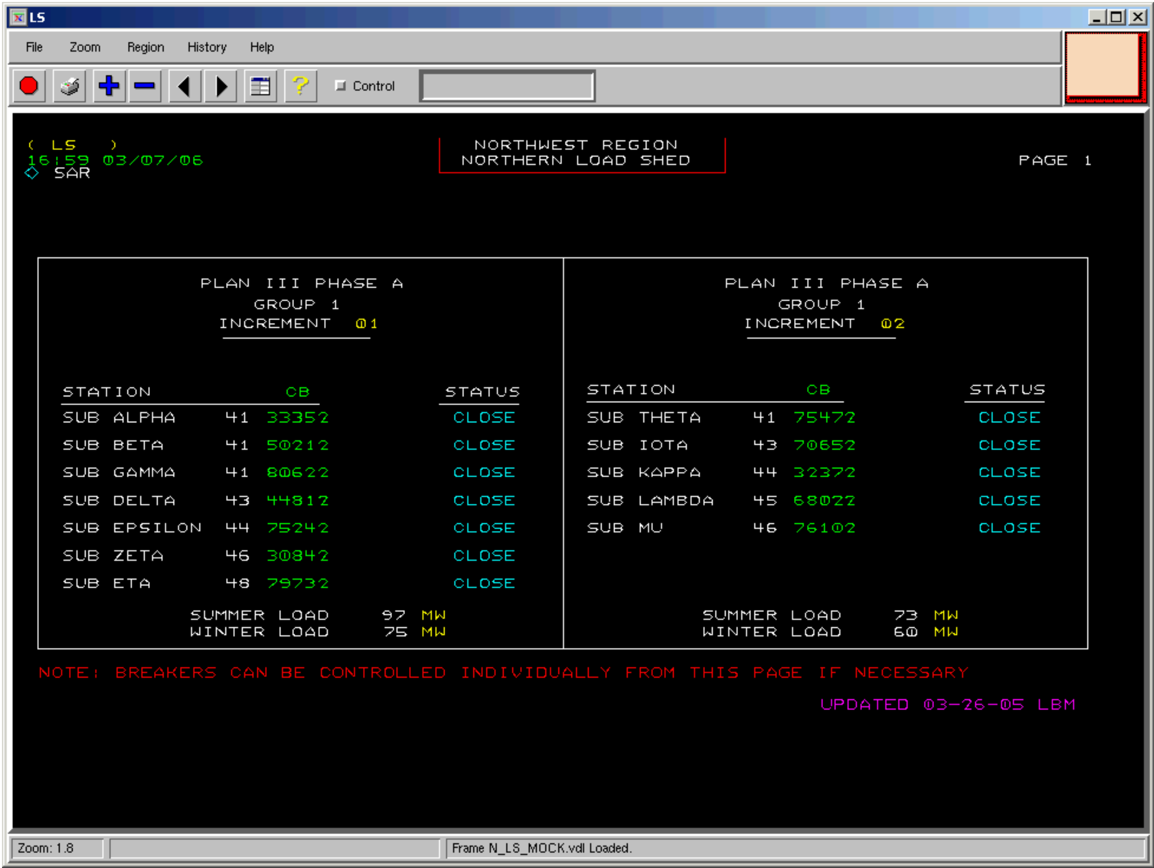


The following screen shot shows the status of each distribution breaker in each load-shed increment (block) in the northwestern region. There are a total of 47 increments in this particular region. In addition to showing the open/close (green/red) status of each breaker, placing the cursor over the breaker symbol generates a pop-up window that identifies the associated substation, breaker number, and other specific information related to the status of the circuit. Any breaker that has a tag on it will have a “T” appear next to it on this screen, and any breaker with a special note associated with it with will have an “N” appear next to it. In the example below, the “N” next to the breaker for circuit 32892 at the Glebe substation is obscured by the pop-up window that identifies the breaker. The pop-up also includes an operating note (redacted for security reasons) highlighted in yellow.

Not only can the status of individual circuits be monitored at any time from this screen, but once load shed is implemented, the progress of load-shed rotation can be monitored as well.

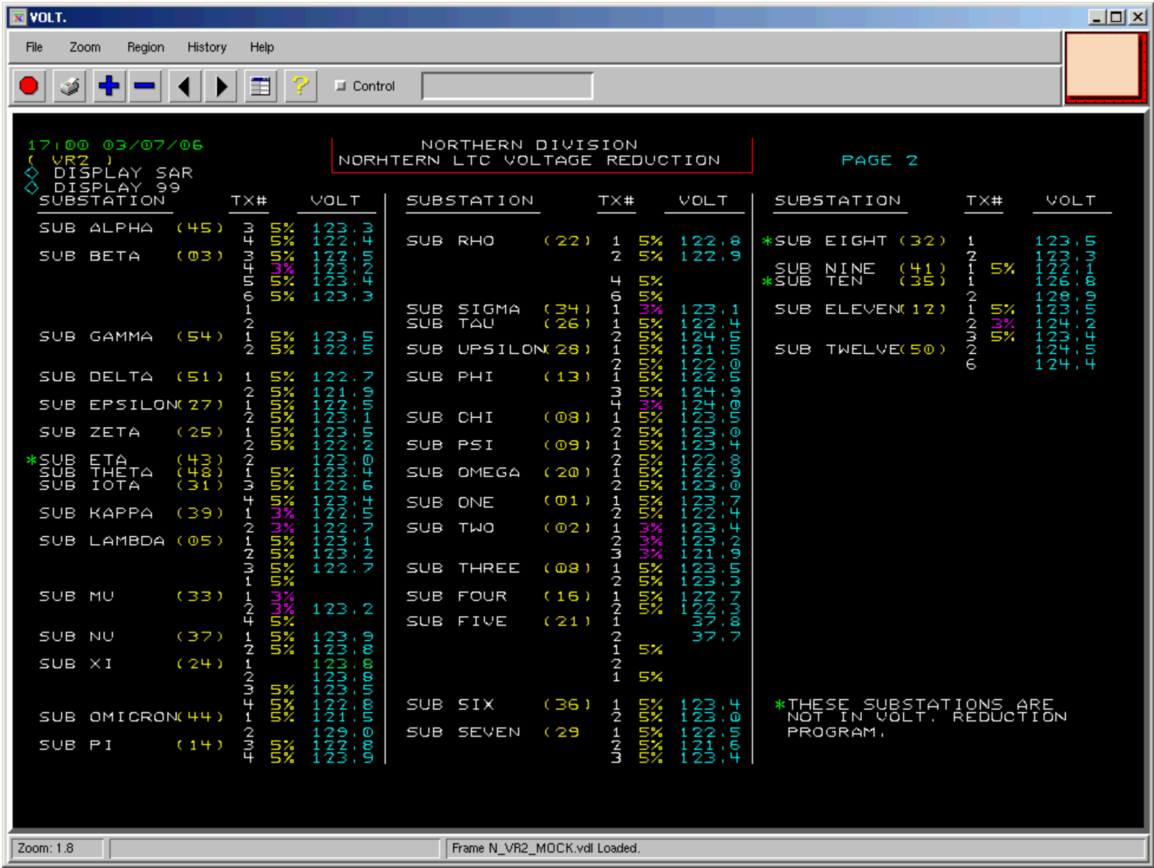


The next example screen shows another view of the individual circuits in the load-shed increments. The circuits that are part of increments 1 and 2 in the northwestern region are shown on this page along with their status and the substations in which they are located. The actual substation names have been replaced with aliases for security reasons. Also shown is the estimated load in each increment that is subject to being shed. These load estimates are based upon historical seasonal peaks.

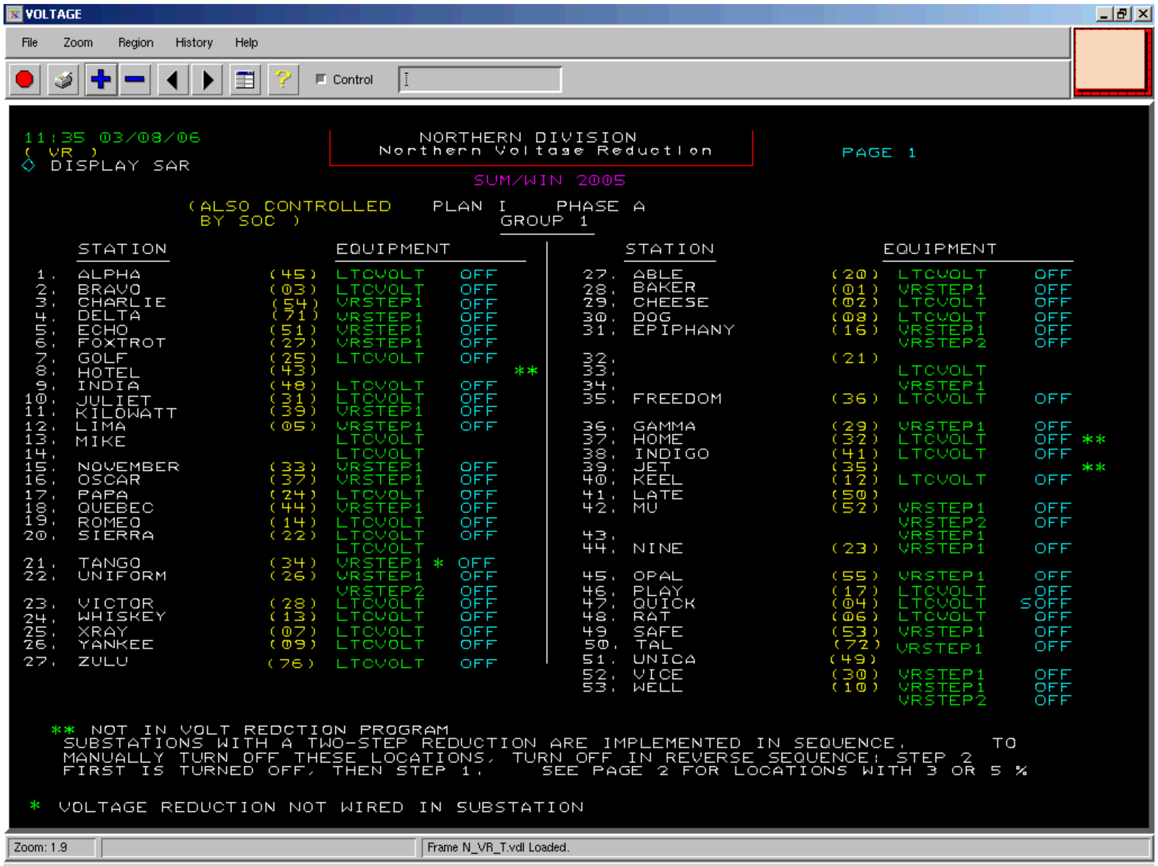


Prior to the development of this application, the previous practice for operator-controllable load-shed was to have the SOC operator (and the DOC operator at the direction of the SOC) use the SCADA systems to send individual circuit breaker trip and close commands to the various substations with circuits eligible for controlled load shedding as identified in the load curtailment plan. This was very time consuming, involved many different substation displays, and made load-shed rotation extremely difficult. Having the load-shed application enhances reliability and situational awareness by allowing quick response to a load-shed directive and overview monitoring of load-shed facility availability and expected response.

The following screen example shows all of the transformers at substations in Dominion's northern division that are controllable for voltage reduction. The actual substation names have been replaced with aliases for security reasons. This screen shows the reduction percentage (3 percent or 5 percent) that is available from each transformer along with the real-time voltage on the associated bus potential transformer secondary (the approximate single-phase voltage that the customers see).



The following screen example shows the status of the voltage reduction equipment at each substation in Dominion's northern division. The actual substation names have been replaced with aliases for security reasons. Equipment statuses preceded by an "S" such as is shown for substation "Quick" on the screen example means that a special order tag has been placed on the equipment. Special order tags usually indicate that some restriction has been placed on the operation of the equipment.



The in-house development of the software to facilitate load shedding and voltage reduction was based upon Dominion's operating needs for implementing its load curtailment plan. System operators provided critical input and feedback during the development. In addition to routine software maintenance of the application performed by the IT staff that supports the DMS, there is an annual, end-to-end load curtailment equipment test to verify correct operation.

Examples of Excellence

EOE-16
Reference — Section 3.6, System Reassessment and Re-posturing
Submitted by — VACAR Subregion of SERC

Description

Tool/Practice Name:	VACAR Guidelines For Addressing Situations Outside of Established Procedures
NERC Registration:	Reliability Coordinator, Transmission Operator, Balancing Authorities

Overview

The VACAR Subregion of SERC has developed documented guidelines to address events on the transmission system that are outside the scope of established operations. These guidelines, which are part of the *VACAR-South Reliability Coordinator Handbook*, are intended for use by the RC working in close coordination with the BAs (TOPs) within the reliability area. These guidelines contain several excellent examples of what to include in a procedure for reassessing and re-posturing the system following an event or events that leave the system in an insecure or unstudied state.

Particularly noteworthy is the section describing a generic approach to problem solving. This approach encompasses assessing the situation, diagnosing the problem, planning corrective actions, implementing the plans, and assessing after the fact the appropriateness of the actions taken. It also stresses communications and coordination among affected parties

The document follows in its entirety.

Procedure Name: Guidelines for Addressing Situations
Revision Date: 1/24/2005
Outside of Established Procedures

VACAR GUIDELINES FOR ADDRESSING SITUATIONS OUTSIDE OF ESTABLISHED PROCEDURES

Purpose

This guideline provides a framework for the reliability coordinator (RC) to use in addressing situations outside of established procedures. The RC shall rely heavily on system expertise that the Control Area (CA) operators have relative to the local area operation of their own systems with regard to problems that may result in the use of this procedure.

Conditions

Various types of conditions may become apparent to the RC that are not addressed in the current Emergency Operating Procedures (EOP). These may include:

• **Over voltage** conditions on a Member system: The RC shall coordinate with the CAs and other RCs to check the status of capacitor banks, voltage control devices, regulated volt-ampere reactive (VAr) reserves. If necessary, the RC will coordinate the removal of lightly loaded Extra High Voltage (EHV) facilities from service or insertion of reactive devices within the affected CA or neighboring CAs.

• **Under voltage** conditions on Member systems: The RC shall coordinate with the member CAs and other RCs to check the status of capacitor banks, voltage control devices, and regulated VAr reserves. If the condition still persists following the validation of the status of all VAr resources, the RC may need to review sales/wheeling schedules for their impact on voltage. It may also be necessary for the CA to consider redispatch of generation.

• **For first contingency transmission overloads** on the bulk transmission network that need to be relieved within a thirty **(30) minute** time frame, the appropriate procedures will be implemented to relieve the overloaded facility. This may include any available local operating procedure or NERC Transmission Loading Relief Procedure (TLRP).

• **For transmission overloads** on the bulk transmission network that need to be relieved immediately, methods listed below will be used to relieve the overloaded facility.

- Removing from service other transmission facilities in the area, which will off-load the overloaded facility.
- Removing from service the overloaded facility itself.
- Return to service any available outaged facilities that will help off-load the overloaded facility.
- Redispatch generation.
- Curtail energy and transmission schedules
- Curtail interruptible customers

• **Stability** of the interconnected network may become a concern of the RC and CA(s). If this is identified as a problem, the RC and the affected CA and other RCs should:

- Verify network topology
  - Determine if local conditions are contributing to the stability problem,
  - If local conditions are not a contributing factor, notify neighboring sub-regional and regional RCs

- Verify the status of Power System Stabilizers (PSSs) in the area.

Problems in other Reliability Coordinator's Security Areas

The problems discussed above (over- and under-voltage, contingency, and stability) may exist in other RC's Reliability Areas and resolution will require coordination between VACAR and these other areas. To the extent that VACAR CAs impact these external problems, the VACAR RC will work, in the manner described above, with those CAs and other RCs to rectify the situation.

Generic Approach to Problem Solving

Should all the above fail to correct problems on the bulk interconnected network under the responsibility of the VACAR RC or problems which the VACAR RC has been requested to help alleviate, the VACAR RC should attempt to solve the problem utilizing a generic approach to problem solving, which will continue to utilize contact with the affected CAs and other RCs. This approach involves five (5) steps. This diagnostic process can aid the RC and system operators in addressing problem situations in a systematic manner. The RC should rely heavily on system expertise that the CAs and other RCs have relative to the local area operation of their own systems with regard to problems that may result in the use of this procedure.

- **Assessment of Situation:** This involves assembling data that is available to the RC, gathering additional data from remote sites and/or systems, and evaluating the evidence. From the large amount of data available, the RC must focus on the data that is critical to the problem. Throughout the process, the RC should remain alert for new data and be prepared to integrate all evidence received. As part of the immediate assessment of the situation, the RC must decide the urgency of the problem and the need for decision or action.

- **Diagnosis of Cause of Problem:** This step involves formulating alternative interpretations of the event, gathering additional information as needed to support or refute the interpretations, and finally determining the most probable cause of the problem. The RC should retain an open mind in reviewing the evidence and examining different possible causes of the problem. Knowledge of previous incidents and of system/equipment history should be used in formulating explanations. A team brainstorming approach including RC and CA resources can be helpful in maintaining the openness at this point in the problem solving process. Once explanations have been formulated, additional information that would help select the explanation can be sought. At this point, the search for information is clearly focused and the questions should be closed rather than open-ended. With further evidence the RC should now be ready to select a working explanation to use in planning a corrective strategy. However, the RC should constantly monitor the system data that may necessitate a change in direction.

- **Planning Corrective Strategy:** When planning a corrective strategy, the RC should identify a workable solution, evaluate the potential consequences of the strategy, communicate the strategy, and plan for contingencies. The strategy should be one that responds to the cause of the problem as identified in the diagnosis. The selected strategy should meet two general guidelines. The strategy should respond to all the identified causes and minimize any potential adverse consequences. In many situations some trade-off of reliability versus economy is involved. In all cases, the RC should plan for contingencies both during and after implementation of the strategy. Once a strategy has been selected, all those involved in its implementation should be informed. All those involved in implementing the strategy and monitoring its effectiveness should be aware of the overall strategy and their role in it. If changes are made, they should also be clearly communicated to all those involved.

- **Implementation of Corrective Strategy:** Implementation of the strategy involves performing the required actions and monitoring the results. All steps of the strategy should be clearly communicated among the affected parties. Confirmation of the steps taken and corresponding results of this strategy should be provided to the RC by the CA(s). The RC should continuously remain alert for new data that may indicate the need for a shift in strategy.

- **After the Fact Analysis:** After the immediate problem has been resolved, the incident should be analyzed to determine whether appropriate actions were taken. After resolution, additional evidence may become available. Real time response to the event should be evaluated and appropriately documented.

EOE-17

Reference — Section 5.1, Display Maintenance Tool
Submitted by — California Mexico Reliability Coordinator (CMRC)

Description

Tool/Practice Name:	Display Maintenance Tool Application
NERC Registration:	Reliability Coordinator

Overview

By using an equivalent display maintenance tool application, CMRC has taken a slightly different approach to ensure that its EMS displays are functioning properly (i.e., showing correct information, linked correctly) to maintain situational awareness for CMRC's operators.

All of CMRC's network application one-lines are derived from auto-generated simplified displays. Most external stations are left in the simplified form. Displays for internal stations are edited to include detailed switching and bus arrangement detail. Elements added to a display are automatically updated in the network model database using the display maintenance tool (through a visual display). This has prevented extended periods of downtimes for certain EMS failures.

Examples of Excellence

EOE-18

Reference — Section 5.2, Change Management Tools and Practices
Submitted by — PJM

Description

Tool/Practice Name: ChPro Change Management Tool

NERC Registration: Reliability Coordinator

Overview

RTBPTF notes that each entity has taken a slightly different approach to ensure that software modifications do not compromise the availability and integrity of critical real-time applications that support operator situational awareness. However, RTBPTF notes that PJM has a feature management system that resides only on their development environment. PJM also has a server identified as the source master server for that environment. Each code change that is made needs to be logged through the feature management system called "ChPro" on the development system. "ChPro" provides audit logging and version control capabilities. Once the code change is logged it can be moved to other environments for testing. Typically these changes are installed and tested on their process control test (PCT) environment, which receives real-time data from their production (PRD) environment to simulate results in the PRD environment. Once tested on the PCT environment, the feature must be logged in a change management system called REMEDY. These features need manager approval as well as operator notification and approval prior to being installed in the PRD environment unless the change is considered an emergency. Emergency changes can be installed immediately upon operator notification and approval to fix a problem. If the change is an emergency change, a REMEDY request must still be submitted for approval by a manager at a later time. Any change installed on the PRD environment is immediately re-tested to insure application integrity and availability. After the change is tested and approved on the PRD environment, it is moved to all other environments to insure synchronization of all systems. The PJM software maintenance tools and processes successfully comply with SAS 70 Type 2 audit standards.

Examples of Excellence

EOE-19

Submitted by — American Electric Power (Central and Southwest)

Description

Tool/Practice Name:	Facilities Monitoring Application
NERC Registration:	Balancing Authority and Transmission Operator

Overview

Using equivalent facilities monitor applications, entities have taken slightly different approaches to ensure that critical equipment and facilities are functioning properly to maintain situational awareness for their operators. Central and Southwest (CSWS) interfaces its facilities monitoring application (called “Big Brother”) with its critical applications monitoring application. This interface provides CSWS with an extremely flexible tool for monitoring and notification (paging) for numerous aspects of it system.

Examples of Excellence

Reference — Section 5.4, Critical Applications Monitoring
Submitted by — Tennessee Valley Authority

Description

Tool/Practice Name:	Critical Applications Monitoring
NERC Registration:	Balancing Authority and Transmission Operator

Overview

Tennessee Valley Authority (TVA) uses a tool that monitors all critical and non-critical processes on their SCADA system. If a process fails, TVA's Network Operations Center can restart the process from a visual display. This has prevented extended downtimes during certain EMS failures.

Examples of Excellence

EOE-21
Reference — Section 5.4, Critical Applications Monitoring
Submitted by — International Transmission Company

Description

Tool/Practice Name:	Critical Applications Monitoring
NERC Registration:	Transmission Operator

Overview

International Transmission Company uses a tool that monitors the status of its state estimator and ICCP data applications. The tool generates text messages to a cell phone, which are automatically sent to an on-call operations engineer when the state estimator aborts and does not converge. When the data flow rate on the ICCP data links stalls, the tool sends text messages to a cell phone, which automatically goes to on-call IT support personnel and an on-call operations engineer.

Examples of Excellence

EOE-22
Reference — Section 5.4, Critical Applications Monitoring
Submitted by — American Transmission Company

Description

Tool/Practice Name:	Critical Applications Monitoring
NERC Registration:	Transmission Operator

Overview

American Transmission Company has created overview displays that not only show system performance but also EMS health checks. These overview displays allow the system operator to determine whether the EMS is operational and functioning properly. System operators are required to display these overview visuals and to notify the on-call EMS contact if a problem appears.

Examples of Excellence

EOE-23
Reference — Section 5.4, Critical Applications Monitoring
Submitted by — American Electric Power (Central and Southwest)

Description

Tool/Practice Name:	Critical Applications Monitoring
NERC Registration:	Transmission Operator

Overview

Central and Southwest (CSWS) interfaces its EMS Facilities Monitoring application (aptly called “Big Brother”) with its critical applications monitor. This interface is an extremely flexible tool for monitoring of and notification (paging) regarding numerous aspects of the CSWS system.

Examples of Excellence

EOE-24
Reference — Section 5.5, Trouble-Reporting Tool
Submitted by — Florida Power and Light

Description

Tool/Practice Name:	Trouble Report System
NERC Registration:	Transmission Operator and Balancing Authority

Overview

Florida Power and Light's (FPL) Trouble Report System (TRS) is a web-based application developed in house to facilitate logging, communication, and tracking of user problems with tools and systems maintained by the computer support group at FPL's System Control Center. Users are primarily operators. In addition to allowing entries of new trouble reports, the application performs administrative functions and can produce different query-based summary reports. The process flow and other functionalities are described below.

New Trouble Report Entry

Whenever a user encounters a problem with a tool or application, s/he can call computer support personnel or initiate a trouble report entry. Even if the user opts to call to report the problem, FPL considers it good practice to initiate a trouble report through TRS to ensure tracking. TRS also has an interface to FPL's e-mail system, so users can track trouble report status and eventual resolution. Trouble reports can be initiated by users or by support personnel that receive a call. When support personnel enter the report, they do so on behalf of the user reporting the problem. Once the user saves the entry, the trouble report status becomes PENDING.

Initial Evaluation

Support group personnel are assigned to periodically scan the TRS for reports with PENDING status and select the appropriate functional area to investigate and resolve each report. When the report is assigned, its status changes to ANALYZE, and an e-mail is automatically issued to the supervisor of the selected functional area notifying him/her of the new trouble report that has been assigned to his/her group.

If information provided by the user is insufficient for personnel to assign a report, the report status can be changed to MORE INFO, which automatically issues an e-mail to the user requesting more information. Once the user provides more information and saves the entry, the status returns to PENDING, and the process begins again.

Functional Area Process

The functional area supervisor, when notified by e-mail of a report, analyzes the problem. (The report can be accessed simply by clicking on the URL link provided in each e-mail issued by TRS.) The supervisor will then do one of the following:

- Assign the trouble report to appropriate personnel — This changes the status of the report to WORK ASSIGNED and generates an e-mail notifying both the staff member assigned to the report and the user that the report has been assigned. The supervisor determines the severity of the problem and assigns a priority to the report: high, medium, or low. The “Trouble Area” and “Application” fields of the report should also be filled in at this time. This information is useful for classifying problems in summary reports.
- Reassign the report to another functional area — The report status remains ANALYZE, and an e-mail is sent to the supervisor of the new functional area.
- Ask for more information regarding the problem — The supervisor can change the status of the report to MORE INFO, which generates an e-mail to the user requesting more information. Once the user provides more information and saves the entry, the status returns to ANALYZE, and an e-mail is issued to the functional area supervisor.

Trouble Resolution

The analyst assigned the trouble report reviews the severity of the problem and determines, based on workload, when to begin work on the problem. During the resolution stage, any of the following may occur:

- Problem is corrected — Once the analyst resolves the problem, s/he changes the report status to FIXED and describes the resolution. If the resolution requires code changes, the “Code Change Req” flag is selected, and modules that have been modified are specified in the resolution description. TRS automatically issues an e-mail to the user who reported the problem and to the functional area supervisor indicating that the problem has been fixed.
- No action could be taken to resolve the problem — This may be a result of an inability to duplicate the problem or determination that resolution of the problem would constitute a system enhancement, which requires that it go through a change management process. In this case, the analyst updates the status of the report to NO ACTION. TRS automatically issues an e-mail notifying the user who reported the problem and the functional area supervisor of the status change.
- Need more information from the user — The analyst can change the status of the report to MORE INFO. This generates an e-mail to the user requesting more information. Once the user provides more information and saves the entry, the status returns to WORK ASSIGNED, and an e-mail is sent to the analyst.

User Feedback

The user who initiated the report should verify that the problem has been corrected or agree that the problem is an enhancement that requires initiation of a change request. In both cases the user should update the status of the trouble report to CLOSED. If s/he disagrees with the resolution, a description of the disagreement is entered, and the status should be changed to NOT FIXED, which generates an e-mail back to the analyst.

Administrative Functions

TRS will e-mail weekly reports to each functional area supervisor listing all outstanding trouble reports assigned to their groups. These reports are copied to management. Outstanding trouble reports are those with a current status of ANALYZE, MORE INFO, WORK ASSIGNED, or NOT FIXED. TRS provides the following statistics on a per-trouble-report basis:

- Time elapsed from a report’s first entry to the system to its assignment to a functional area
- Time elapsed from assignment to a functional area to assignment to an analyst
- Time elapsed from assignment to an analyst to resolution
- Total time spent on a trouble report (from initial entry to completion)
- Total number of times that a trouble report was returned by user as not fixed

Standards Announcement

Comment Period Open
June 10–July 11, 2009

Now available at: http://www.nerc.com/filez/standards/Project2009-02_Real_Time_Tools.html

Standard Authorization Request (SAR) for Real-time Tools (Project 2009-02)

The Standards Committee has posted a proposed SAR for a 30-day comment period **until July 11, 2009**.

Please use this electronic form to submit comments. If you experience any difficulties in using the electronic form, please contact Lauren Koller at Lauren.Koller@nerc.net.

The status, background, and supporting documents for this project — including an off-line, unofficial copy of the questions listed in the comment form — are posted at the following site: http://www.nerc.com/filez/standards/Project2009-02_Real_Time_Tools.html

Project Background:

According to the *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations,* dated April 2004, a principal cause of the August 14 blackout was a lack of situational awareness, due in part to inadequate reliability tools. Recommendation 22 of the report states, "Evaluate and adopt better real-time tools for operators and reliability coordinators." NERC's Operating Committee formed the Real-time Tools Best Practices Task Force (RTBPTF) to evaluate real-time tools and their usage within the industry. The Task Force produced a report, *Real-Time Tools Survey Analysis and Recommendations*, in March 2008 that included recommendations for the functionality, performance, and management of real-time tools: http://www.nerc.com/docs/oc/rtbptf/TOC_ExecSumm_Intro_2_1_08.pdf.

The SAR addresses selected recommendations in the RTBPTF Report as determined by the Real-time Best Practices Standards Study Group: Project 2009-02. The SAR proposes developing requirements for the functionality, performance, and management of real-time tools for reliability coordinators, transmission operators, and balancing authorities for use by their system operators in support of reliable system operations, with a focus on alarming, telemetry, and network analysis.

Standards Development Process

The Reliability Standards Development Procedure contains all the procedures governing the standards development process. The success of the NERC standards development process depends on stakeholder participation. We extend our thanks to all those who participate.

For more information or assistance,
please contact Shaun Streeter at shaun.streeter@nerc.net or at 609.452.8060.

No
ATC believes that this should be addressed in the certification process, and if necessary a re-certification process. If that effort fails to achieve the overall goal of this SAR, (Minimum types of Real-time tools) then we would be more open to a standards develop project.
No
Please see our comment to question 1.
Yes
This approach should be incorporated into the certification/re-certification process.
Yes
Please see our comment to question 1.
No
If this SAR is continued then the team needs to provide more information about the proposed performance metrics. (i.e. Definition(s), Calculation(s), Exclusion(s) and Goal(s)) In addition, the team should gather and provide information that can support the establishment of a minimum performance level. Setting a performance level will require strong technical support.
A new definition will likely be needed if this project moves into a standards development phase;

otherwise the existing definition may be suitable. (The certification / re-certification may not need to define Real-time but only identify minimum tools required for certification.)
Certification Process
and re-certification process
Not aware of anything that applies.

self
Yes
Yes
Yes
Yes
Yes
No
Wordsmithing the definition of real time is a huge waste of (real) time. Everyone knows that real time data is between two and five seconds old (maybe even longer) depending on the scan rate. There has been some type of sabotage reporting rule or requirement for over 30 years because it was the sexy and politically correct thing to do even though there was no way that a System Operator, with his office in the middle of a corn field, knew if the line trip was due to sabotage or not. Even when the troubleman arrived at the scene of the outage, he still may not be able to determine if the tower fell down because it was a sabotage event or a local farmer removing some of the tower's bracing in order to use the bracing to hold up his corn crib.
Yes
Although these GOP requirements should be part of the interconnection agreement between the Generator and the Transmission Provider, it may be more straight forward to have these requirements addressed in this SAR.
Reliability Standard
I am not sure what is meant by the certification process. I thought that the certification process was a one time deal. If the certification process is conducted annually, you may be able to not have this as a reliability standard. However if an entity loses their certification what happens to then and more important what happens to reliability.
There shouldn't be any.
Individual
Scott Vidler
Hydro One
Yes
From my travels and contacts I've witnessessed extreme variances in tool capability among control centres. A lack of standards has allowed companies to cut corners while others strive for excellence.
Yes
I agree if items such as wide area displays, identificaion of equipment outages (tagging, colours) which are crucial for visualization are being considered in other standards.
Yes
It is the end result that counts - how you get there will within reason be driven by the standards.
Yes
Network analysis is so broad that many functions can be included in this category i.e. dynamic

equipment ratings, short circuit analysis, breaker duty cyclee etc that this SAR can be as broad as required.
No
One thing not indicated under performance metrics is actual performance i.e. alarm bursts, state estimator solve time or frequency of run, contingency analysis completeion time. If a SE only runs every 30min and takes 10min to solve how effective is it?
No
It is a good discussion point but it is splitting hairs a bit. Real Time is what you see now whether it took 5 minutes to get all the information or SE to solve. If the concept is to define how long it takes to refresh the data i.e. a 2 second refresh then that will drive home performance.
Yes
A lack of situation awarness, alarms and telemetry that ends up with a generator(s) contingency will have an impact on the reliability of an area so it is as important.
Reliability Standard
Group
WECC Reliability Coordination
Yes
Our only concern is that the standard may outpace the available technology. Also, only tools that are applicable to all interconnections should be inlcuded in the standard.
Yes
It appears that there may be a dollar and resource impact associated with the new and revised standards, so a phased approach may be required.
Yes
Although it appears that in the survey results that some items are specifically mandated.
No
The survey results focus on additional items not listed above and do include data requirements such as day ahead study data requirments, path limts requirement and special protection schemes monitoring applicability.
Yes
The word quality needs to be clearly defined and measurable.
Yes
Yes
Reliability Standard
none at this time
We have an overall concern that an implementation process needs to be coordinated to minimize the impact to organizations that do not have the current resources or dollars to immediately implement the proposed changes. Also, it appears the SAR requires specific procedures rather than guidelines for event mitigtion, which does not provide the operator or RC leaway to assess all the variabiles in the interconnection. The role and responsibility for each requirement also needs to be clearly defined.
Group
NERC RTOSDT
Yes
The RTOSDT technically takes no position on the reliability need for requirements that state which specific tools are required, as we believe this to be the answer to the "how" question as opposed to the "what" question which is the nature of a true reliability requirement.
Yes

Again, the RTOSDT takes no position on the scope.
Yes
The RTOSDT agrees, however, it seems unlikely to be achievable in this case. Discussions surrounding analytical capabilities seemingly always devolve to specific tools.
Yes
The RTOSDT takes no position on this issue.
Yes
The RTOSDT agrees that a set of metrics is useful. Further, the RTOSDT believes that NERC must grapple with the concept that no information system is perfect. That is, requirements that involve information systems should only specify a "designed" level of performance, not the actual level of performance. It is nonproductive to investigate and fine an entity for failing to have two scans of an RTU, for example. The intent of a requirement related to information systems should always allow for reasonable failover times if redundancy is required and should allow for something less than 6 sigma performance, especially considering that communication networks outside of the control of reliability entities may have at best 2 sigma performance.
Yes
The RTOSDT takes no position on this at this time. However, unintended consequences may occur. This needs a lot more explanation to the industry.
Yes
The RTOSDT can see no reason to preclude the adding of the GOP at the SDT phase of the project.
Certification Process
Discussions at the RTOSDT have generally yielded consensus that these are basically one-time requirements, at certification time, and which specify the "designed-in" level of performance, while not focusing on the actual performance in absolute terms. That is, any actual performance requirements should be statistically sound. For example, it is patently absurd to believe that BAL-005-0.1b R8, which requires ACE calculation at least every 6 seconds, is actually possible with real computer systems. On a design basis, this means that a hot backup with failover within a couple of minutes is required. On an actual performance basis, this is far better than the up-time required of space shuttle computers. Something like 2 sigma or 3 sigma performance for actual results is quite possibly all that is needed for the uptime for these tools.
N/A
FERC Order 693, paragraphs 1659 to 1665, mandate the addition of a requirement in the TOP standards for a minimum set of analytical tools for carrying out TOP reliability functions and that relay closing phase angle data be presented to operations staff: Tools and capabilities are a very broad, yet specialized topic that demands industry input of a more focused nature than that possible in current Project 2007-03 (Real-time Operations) upon which the RTOSDT is working. The RTOSDT believes that the Subject Matter Experts (SMEs) that will be gathered in support of this SAR will be better qualified to address this issue, and to elicit industry input, than the operational SMEs supporting Project 2007-03. The RTOSDT is basing its response to FERC for this matter on this item being vetted and supported by Project 2009-02 as appropriate.
Individual
Alice Murdock
Xcel Energy
No
Several standards (IRO-002, TOP-006, TOP-008) already address the issues identified in this SAR. Rather than develop a new standard, we recommend evaluate or incorporate into an existing project for these standards.
No
There is concern that the SAR may be expecting research and development of tools. This is not an appropriate use of a SAR.
Yes
No
It is not clear as to how far reaching standards for these functions would be. For example, we would not be in support of anything that would infer the need to install duplicate instruments to provide information to a Reliability Coordinator (as in most cases this data is acquired by the TOP and BA

and then passed to the RC).
No
Any requirements created to impose metrics should allow for exceptions for extended outages of equipment for uncontrollable reasons. As written in the recommendation report, an outage on a real time tool for as short as a few hours could create significant non-compliance events, while not having any impact to the reliability of the system.
No
Use of industry groups such as the Transmission Owners and Operators Forum, and EPRI should be considered in development of best practices and tools for use in real time operations.
Group
Southern Company
Yes
In the absense of a certification process with re-certification, new standards should be established only if the same end can't be reached by revising existing standards. The RTBPTF's report gave several examples where real-time tools were mentioned but not well defined in existing standards. The SAR team should begin developing new standards only after they have determined that the same results can't be obtained by revising existing standards.
Yes
This SAR covers the concerns spelled out in the Real-time Tools Survey Analysis and Recommendations report.
Yes
Yes
No
Availability and quality would be acceptable measureable metrics. Change management, maintenance coordination, and failure notification are processes and would have to be measured through documentation.
No
If a NERC Glossary term used in other standards is re-defined than the meaning of those standards has been changed without revision. The IRO standards use real-time as a description of a planning horizon or describing the data being used. Personnel operating the bulk power system understand that real-time data can be several seconds to several minutes old. The team may want to define the limits of near real-time data.
Yes
Certification Process
These requirements need to be included in an entity's certification process that includes periodic re-certification. This would require entities to certify that they have the tools needed to perform these functions and mechanisms in place to continue to perform the functions.
Individual
John Brockhan
CenterPoint Energy
No
CenterPoint Energy does not agree there is a reliability-related need for these proposed standards. The Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations reports on page 19 First Energy (FE) had state estimation and contingency analysis tools. The "…tools were not used to assess system conditions, violating NERC Operating

Policy 5, Section C, Requirement 3, and Policy 4, Section A, Requirement 5. FE personnel did not ensure that their Real-Time Contingency Analysis (RTCA) was a functional and effective EMS application as required by NERC Policy 2, Section A, Requirement 1." CenterPoint Energy agrees that real-time monitoring and network analysis tools are necessary however, CenterPoint Energy believes the appropriate forum to evaluate an entities tools and their use would be during the certification process for a RC, BA, or TOP. Items such as functionality, performance, and management of the available tools as well as availability and quality of the entity's tools and how the entity uses the tools in their operation could be measured as well.
No
See response to Q1.

James H. Sorrels, Jr.
American Electric Power
No
AEP fully supports the need for entities to have an adequate tool set to operate in a reliable manner. However, it is AEP's belief that that reliability issues that this SAR intends to address are not resulting from a void in the reliability standards, but instead in the current certification processes. For example, some RTOs require that there are qualified systems in place prior to operating, while others require that individuals be certified. We would support that both elements are necessary, that is the right tool set verified and individuals having NERC certification, and that this occur in advance. Using the NERC certification process of functional entities to ensure that the right tool set is in place and operating correctly is preferable to allowing, by administrative registration alone, to begin operating and then, afterwards, try to invoke standards to address operating issues that could have been avoided up-front. The certification process will need to also be modified beyond a single verification to a periodic process to ensure tools remain in place and are operating as expected.
No
AEP believes that these actions are largely covered in the existing standards, including those shown below (Table 1) in the related SAR functions format. Repetition of requirements across multiple standards may create ambiguity if alternative requirements or methods are defined from one to the other. It also establishes the possibility of compounding violations for a single infraction. To the extent that new requirements are needed to address operational gaps, these could be made in the next revision of the applicable existing standards, which is to be done on a periodic basis. TABLE I - Existing NERC Reliability Standards addressing Alarming, Telemetry, Network Analysis, Related Performance Metrics (Availability and Quality), and Processes and Procedures supporting Real-Time Tools (Change Mgt., Maintenance Coordination, and Failure Notification) : Alarming COM-001-1.1, does have some language related to the alarming of vital telecommunications facilities for voice and data. TOP-006-2 stress the importance of monitoring equipment to be used to 'alarm' or bring to the attention of operating personnel important deviations in operating conditions and to indicate, if appropriate, the need for corrective action. IRO-002-2, gives direction on the alarming management and awareness systems that need to be in place for the RC. Telemetry BAL-001-0,

dealing with the ACE equation along with Control Performance Standards (CPS1 and CPS2) BAL-004-0, addressing Time Error Corrections BAL-005-0.1b, focuses on the telemetry components necessary for calculating the ACE equation BAL-006-1.1, tasks the Balancing Authorities to calculate and record hourly Inadvertent Interchange IRO-004-1, details the information that needs to be sent to the RC for reliability studies to be performed IRO-005-3, breaks down most of the parameters that a RC would need to receive for monitoring the BES TOP-002-2, highlights that changes in transmission facility status, along with ratings should be monitored and conveyed to the RC and BA TOP-005-2 is the Operational Reliability Information standard that lays out all of the data that needs to be updated at least every ten minutes TOP-006-2 is another standard focused on monitoring system conditions. VAR-001-1 also is offering details on what data should be pipelined back to the operating control centers from the BES. Network Analysis IRO-004-1, discusses the ability for the RC, TO, and BA to conduct next-day reliability analyses to ensure that the BES can be operated reliably. TOP-002-2, looks at the performance of current-day, next-day, and studies operational studies in conjunction with neighboring BA(s) and TO(s). TOP-002-2, also address the thermal and voltage contingency analysis that needs to be performed. IRO-002-2, details the analysis that needs to take place via state estimation and other visualization tools. Performance Metrics for Availability and Quality Availability Availability BAL-005-0.1b, R8 looks at SCADA availability to gather data and calculate ACE. This requirement also address the availability of Frequency Metering equipment (99.95%). COM-001-1.1, stresses the diversity and redundancy of communication paths for the available exchange of Interconnection and operating information, internally and externally to AEP. EOP-008-0, emphasizes the development of a plan to ensure the monitoring and control of transmission, distribution and generation assets even with the loss of the Control Center. Quality BAL-005-0.1b, R17 breaks down the accuracy of the metering devices for time error and frequency measurements BAL-006-1.1, requires adjacent balancing authorities to have common megawatt-hour meters at the interconnection point. IRO-005-3, discusses the importance of operating to the most limiting element if there is a discrepancy between various entities monitoring the same facilities. TOP-006-2 generically states that sufficient metering of suitable range, accuracy and sampling rate (if applicable) to ensure accurate and timely monitoring of operating conditions. Processes and Procedures supporting Real-Time Tools: Change Mgt., Maintenance Coordination, and Failure Notification Change Management FAC-009-1, obligates the communication to RC(s), PA(s), TP(s), and TO(s) for new facility ratings on the Bulk Electric System. TOP-002-2, implies that there should be a facility change notification system in place for neighboring entities to use uniform line identifiers when referring to interconnected facilities. BAL-004-0, addressing Time Error Corrections Maintenance Coordination FAC-009-1, it is implied that these changes will be applied to the real time computer model with alterations to facility ratings on the Bulk Electric System. TOP-002-2, talks about each BA and TO maintaining accurate computer models for analyzing and planning system operations. Failure Notification IRO-005-3, highlights the responsibility to identify significant issues with ACE that can attribute to other errors, such as frequency error and Time error.
No
While we do agree that "what," not "how," is the correct approach to describe the required real time tools, we believe it should be established in the certification process as described in item #1 above. While it is easy to say we will confine ourselves to "what," it's difficult to prevent establishing criteria that inadvertently leads to a particular "how." Should "how" occur, it limits opportunities for improvements and innovation, and could hamper better results. AEP agrees with this approach of describing "what" needs to be done, as opposed to "how" to do it, as this preferred approach encourages new technology development in achieving the intent of the standard.
No
As described in item #2 above, we believe that these areas of focus are already covered in the existing standards (Table I). NERC is actively involved in consolidating standards in the revision process as witnessed in Project 2006-03. Creating new standards unnecessarily would be counter productive to this trend.
No
AEP believes that these actions are largely covered in the existing standards, including those shown previously (Table 1) in the related SAR functions format. Repetition of requirements across multiple standards may create ambiguity if alternative requirements or methods are defined from one to the other. It also establishes the possibility of compounding violations for a single infraction. To the extent that new requirements are needed to address operational gaps, these could be made in the next revision of the applicable existing standards. In any case, if this SAR proceeds, it must be

limited to the “what” issues of “availability” and “quality”, and NOT on the “How” issues of "change management", "maintenance coordination", and "failure notification."
No
Real-time is a precisely NERC defined term. In addition the Real-time term is highly integrated in the existing standards. Re-defining the term could have a significant impact on a wide-range of existing standards.
No
AEP does not believe that it is necessary to include the GOP as an applicable function for this SAR, as data requirements are specified in existing standards. As mentioned in Item #1, using the NERC certification process of functional entities to ensure that the right tool set is in place and operating correctly is preferable to allowing, by administrative registration alone, to begin operating and then, afterwards, try to invoke standards to address operating issues that could have been avoided up-front.
Certification Process
It is AEP’s belief that that reliability issues that this SAR intends to address are not resulting from a void in the reliability standards, but instead in the current NERC functional entities certification processes. A participant should have, upfront, at least the tool set to operate at an adequate level. The certification process is the appropriate forum for checking the systems. Furthermore, the NERC functional entities certification process could provide periodic checks to maintain certification by ensuring that the tool set remains in place. The upfront verification becomes a must as one considers that potentially thousands of non-traditional generation facilities may be interconnected in the near term.
There should not be differences in the required tool sets, based on regional differences, if the requirements stay at the “what” level.
No further comments at this time.

Cityof Tallahassee (TAL)1
No
While it should be mandatory for the RC’s to have these reliability tools, it is a “best practice” for many of the TO’s. For many other TO’s it would be overkill to have to establish these programs for a relatively small area that is fed from only a couple of lines. How does the applicability change for the size of the organization? Standards should be the MINIMUM needed to operate reliably, not a culmination of the industries “best practices”.
No
This should be targeted to the RC’s initially. Let’s get it up and running for them before we make it mandatory for the TO’s and BA’s. Many TO’s and BA’s will pursue them during the interim because they will know it is coming and can begin the long trek to get there.
No
While I can appreciate NERC trying to avoid mentioning specific brand names, there is no point in not saying you have to have a Contingency Analysis Program if that is what you want us to have. The continued interpretation of what NERC wants becomes a guessing game and we don’t find out that we guessed wrong until we are audited.
No
See response to question 1. Network Analysis does not need to be a requirement for smaller TO’s. Until we can provide some way of avoiding the large expense without a measurable increase in reliability, we should not be pushing this function onto the TO. The TO’s SHOULD be responsible for providing the data needed to the RC so his model works properly.
No
The SAR identifies 2 performance metrics, Availability and Quality. The remaining three functions are not metrics; they will be requirements to ensure the entities have them. The use of metrics for enforcement will become contentious. If I say I am sending data to the RC over my data link, but he says he is not getting it, who gets charged with the non-availability or reduced quality? If the problem is with a third party communication (Sprint, AT&T, etc) why should I get penalized for the “network” failure? There are too many things beyond the control of the entity to make it a “mandatory and enforceable” metric.

Yes
Yes
Generator data is an important set of data for real time modeling.
While I still disagree with a need for it to be a standard, IF it is moved to the Certification process, how will you monitor it on an ongoing basis? How will you ensure the currently registered entities have the tools?
- I must reiterate that a fully functional Network Analysis tool (Contingency Analysis) is a "Best Practice" and not a requirement for many TO's and BA's. I know of a case where the TO is not allowed to vote on Standard development because they do not own enough miles of transmission lines, but they would have to have a CA program by this SAR. The following comments are directly related to the Real-Time Tools Survey Analysis and Recommendations (Final Report) but do apply to the SAR. - Too wide of a "wide area view" may be detrimental to many TO/BA's also. If the RC is watching over the entire RC area, and the TO/BA is watching over a smaller portion with a large portion equivalized, and the RC's model goes down because of bad telemetry in another part of the RC area, the TO/BA's model may still be functional because it is not reliant upon the bad data for proper operation. - On page 27 of the Executive Summary, the RTBPTF identifies the need to address the definition of the Bulk Electric System. This should be done before any additional standards requiring the use of the definition are allowed to proceed. There is still not a good understanding of what it needs to be to ensure that it is reliable. Lets get this hurdle crossed before we make more references to it. - On page 17, Situational Awareness Practices: The first sentence "The task force concludes that documented conservative operations practices are a key element of situational awareness practices and thus includes conservative operations plans in its recommendations." This recommendation appears contrary to the desires of FERC to operate closer to the edge to allow maximum trade to occur based on the ATC standards undergoing revision/review. We should not have competing standards. - On page 25, Awareness of Load-Shed Capability: This "awareness" does no good if the operator does not pull the trigger. THIS is the major cause of the August 14, 2003 blackout and a recurrent theme of recent blackouts. The "word on the street" (from Compliance) is that if you have to shed load (an event), you will be investigated for compliance violations because you must have done something wrong to get to that condition. What message is that sending to the operators? - On page 29, Issue #6: Adequate Funding for Staffing for Real-Time Tools and Support Should be Ensured. This area could not be analyzed by the RTBPTF. However, it did not preclude them from making numerous recommendations to enact the Real-Time tools. I do not like creating standards or requirements without any idea of how it will financially impact entities. This WILL cost a significant amount of money to enact. While many entities (as evidenced by the participation in the survey") are already engaged in pursuing these standards, or want to, the financial burden created by making it mandatory and enforceable will have deleterious effect on reliability. The money is going to come from somewhere. Be it from rate increases or diversion of funds from other projects, delaying the construction needed to fix what is going to be shown on the CA program. The managers of the Reliability Entities are fully aware of the importance of supporting NERC Standards.

No
Most Transmission Operators (TOP) and Reliability Coordinators (RC) typically operate out of one control facility with information that expands beyond that provided by facilities under their direct control. There are protocols for coordinating operations of multiple facilities operated by different entities. Most Generator Operators (GOP) operate out a control room that contains information ONLY on facilities directly under that GOP's control. They are no protocols for coordinated operation of generating facilities. GOPs are to follow directives of the TOP and RC. Also, the federal/state codes/standards of conduct may prohibit dissemination of certain information between the RC/TOP and GOP entities. We strongly believe that placing new compliance requirements in this SAR on all generators is beyond the scope of what GOPs should be functionally doing in almost all generation locations on the bulk electric system and hence advancement of this standard with the inclusion in GOP applicability will actually create unnecessary complexity in operating the bulk electric system.
Certification Process
Individual
Greg Rowland
Duke Energy
Yes
However we are very concerned that the action to revise existing standards or develop new standards could be overly prescriptive. The requirements should remain at a high level, and focus on the "what", as opposed to the "how". The Introduction to the "Real-Time Tools Survey Analysis and Recommendations Final Report" contains 40 recommendations related to new or revised reliability standards; and we believe that many of these recommendations are too prescriptive to be placed in a reliability standard. This SAR should not become a project to implement all 40 of those recommendations. Additionally, we believe that many of these items more properly belong in an entity certification process and not in a Standard. The certification process should address core functionality tools. Standards should be used to address the operational application of these tools. See response to question #8.
No
We believe that the scope is too large to be manageable, and should be broken up into multiple projects.
Yes
See our comment to question #1 above. We are concerned that if requirements are overly prescriptive, they are describing "how" instead of "what".
Yes
No
These are good metrics, but they don't belong in a reliability standard. Performance metrics should be implemented and enforced as part of the certification process.
Yes

Yes
Certification Process
We believe that the high level requirements for functionality should be in the reliability standards, and that the certification process should contain performance metrics and procedures related to change management, maintenance coordination and failure notification. See response to question #1.
None
The drafting team should be very careful not to replicate requirements in multiple standards. For example TOP-008-1 Requirement R4 currently states: "The Transmission Operator shall have sufficient information and analysis tools to determine the cause(s) of SOL violations. This analysis shall be conducted in all operating timeframes. The Transmission Operator shall use the results of these analyses to immediately mitigate the SOL violation."

Smaller entities operating within the bulk electric system may bear a higher burden than larger ones. The benefits of providing real-time network analysis for these smaller entities may be far less than the costs.
No
"Quality" should not be included. "Quality" is fundamentally subjective and cannot be measured
Yes

There will be an inherent delay in the processing of applications, processing of data and the identification of contingency measures related to real time analysis for as much as 15 minutes. On the other hand, typical telemetry updates of data to the user display are around 2-4 seconds.
No
Generator Operators provide alarming and telemetry for their own facilities and only a small amount of this data is typically available to assist in determining the security of the bulk power system. In addition, Generator Operators do not normally perform network analysis.

Yes
Agree that it is very important that a standard or certification process for validating Real Time Tools does not direct the applicable entities to use specific tools. Exelon endorses the "what", not the "how" approach as emphasized in the SAR.
Yes
Exelon suggests historical data (storage and retrieval) should also be considered as an appropriate function. Also, while these may be the right functions for Real Time Tools, a total systems approach should be emphasized as opposed to focusing on "silos" of information and functions, RTU data, hardware, software etc.
No
Exelon agrees performance metrics are important but we seek clarification concerning how quality, maintenance coordination, failure notification and especially change management are to be measured.
No
Exelon does not endorse a re-definition of Real-time.
No
Exelon sees no value in including the Generator Operator in the standard applicability. Data exchange and communication requirements are covered in other standards such as the COM and IRO standards. Additionally, RTO's, BA's and Transmission Owners and Operators typically specify in Interconnection Guidelines, Operating or Reliability Agreements and Manuals, what data must be shared between the Reliability Entities and the Generator Operators so as to support Real-time operational analysis.
Certification Process
Exelon believes the Certification Process as specified in the ROP, Organization Registration and Certification Manual, Appendix 5, would be the best way to verify that entities performing the reliability functions are adequately equipped to do so.
Not aware of the need for either.
Exelon appreciates the opportunity to comment on this SAR and commends the Real-Time Tools Best Practices Task Force for the work done to produce the Real-Time Tools Survey Analysis and Recommendations Final Report.

Ameren
Yes
Yes
Yes
This is the correct approach. Tools will change over time. Defining the “what” should be the focus. Leave the technical “how” to those developing solutions.
No
The SAR should include all aspects of the “Reliability Toolbox” as defined in the RTBPTF report.
Yes

Yes
Clarification of this term could be beneficial. “Real Time” can indicate significantly different time periods depending on the point of view. With the advent of new technologies such as phasor measurement units with a much higher sample rate, real time takes a very different meaning as compared to the traditional “seconds” based sample rates utilized in most current EMS/SCADA systems.
No
It states that there would be a focus on Alarming to alert on events and conditions affecting the state of the BES, Telemetry to provide status and analog values in real time (status of what?), and Network Analysis for simulating impact of what-if events. For Alarming, what action would a GOP take in response to an alarm, that would be independent of what GOP would be directed to do by TO or BA or RC? GOP is already subject to plenty of other NERC Reliability Standards that state that the GOP has to do what the BA/TO/RC tell him/her to do in order to preserve the BES integrity. For Telemetry, regarding status (if assume of Transmission Components) inreal-time operation, doesn’t that violate FERC Code of Conduct, since GOP is not supposed to know about Transmission information that may give him/her an advantage in the market? And as for Network Analysis, that has nothing to do with a GOP.
Whether the eventual approach is determined to be new or updated Reliability Standards or changes to the Certification Process the decision should be left up to the SAR drafting team.

See comments for Question 8
Certification Process
Certified entities have been determined as capable of meeting the all applicable requirements. A new standard setting forth requirements for the tools employed by registered entities to meet existing requirements is redundant. Moreover, having NERC establish either functional or technical specifications for real-time systems will stifle innovation and unnecessarily lead many entities, who are currently meeting existing requirements, to invest resources in altering and not necessarily improving their existing real-time tools. It is better to leave the development of functional and technical specifications of rapidly changing technology to buyers and responding vendors. A failure on the part of registered entities to employ adequate real-time systems will in all likelihood lead to non-compliance with one or more existing requirements. It is nonsensical to describe a system that enables its owner/operator to meet BES reliability requirements as in any way insufficient.
Individual

RRI Energy
No
For the RC, TOP and BA "Yes" in some fashion but the SAR should not be applicable to a GOP. The GOP is not a system operator at the same level as a RC, TOP and BA. We do not have the information on the real time status of the BES. We do not know transformer loadings (other than our GSU), transmission line loadings, generator status (other than our own) and details of demand (local load and projected load). GOP's by statute are prohibited from knowing this information. A standard is not needed to mandate that we have real time tools. The GOP's EMS has the necessary

tools for the GOP to comply with the direction given them by the RC, TOP and BA. The GOP is required by the IA and market rules to follow the direction of the RC, TOP and BA. GOP is included as a System Operator but we believe that the definition should be modified. We plan to submit a SAR to request this change.
No
See comments from Question 1. This SAR should not include GOP in the applicability section.
Yes
Provided that the lack of the how will not cause an issue during an audit.
No
The SAR's focus on "alarming, telemetry and network analysis" I believe supports dropping GOP from the applicability. Our EMS contains the alarms and telemetry needed to comply with standards and market rules. What level of network analysis does the SAR contemplate a GOP performing? Further, if a GOP feels that it needs to have unit AVR mode telemetry to insure compliance to VAR-002 then the GOP will add that alarm to its EMS. An additional standard requirement is not needed for the GOP to have the necessary real time tools to support ALR of the BES.
No
I was unable from the SAR to understand why their was a need to redefine Real-time.
No
See previous comments.
Certification Process
Group
Northeast Power Coordinating Council
Yes
No
The scope of the SAR is too "invasive" to operations. The SAR should address the "output" requirements for the hardware and software-- operators must be provided with the information "results" they need to know to determine how the system is behaving real time, and also for possible system configurations (e.g. contingency analysis). Even though in the Brief Description section of the SAR it states "The intent is to describe 'what' needs to be done but not 'how' to do it." the performance and management of tools falls into the 'how' category. While NPCC suports the material in the RTBPTF Real-time Tools Survey Analysis and Recommendations report, the Standard should be limited to stating the reliability objectives of the Real-time Tools, leaving to each Registered Entity that must comply with the Standard the decision on how they are going to meet these objectives.
No
NPCC agrees that the SAR needs to emphasize the "what" that needs to be done to ensure the reliable and effective functionality, performance, and management of Real-time tools, not the "how" to do it. General categories of types of tools, such as state estimators, contingency analysis programs, etc. can be mentioned. How the results or outputs from those tools are generated, or the management of those tools outside the operating floor, are outside the scope of a standard. The results and of those tools and how they are used (and ease of use), are the most important issues.
No
NPCC agrees that the functions stated are correct, but not all inclusive. The SAR needs to clarify that all of the functions contained in the Real Time Tools Report are not being addressed at this time due to the expansiveness of the RTBPTF report. There should be a fourth required functionality identified as Control. Control would include the application of and methods to ensure control capability is maintained at a control center and remote substations.
No
The statement in Question 5 should be worded "The SAR details the need for performance metrics for alarming, telemetry, and network analysis functionalities, with the considerations of availability,

quality, change management, maintenance coordination, and failure notification." What is meant by the term "change management"?
Yes
NPCC agrees that the current definition that exists in the NERC Glossary of Terms where Real-Time is defined as "Present time as opposed to future time" is inadequate and needs to be redefined. Suggested rewording is: Real-time: 1. Existing or presently occurring. 2. In an information gathering or analysis environment, real time data and a time window allowed for its processing.
Yes
Reliability Standard
From the NERC Reliability Standards Development Procedure, ""Reliability Standard" means a requirement to provide for reliable operation of the bulk power system…". The ideas proposed in this SAR meet that definition, and belong in a reliability standard. NPCC believes that the certification of a function is only a snapshot in time. With technology continuously changing, there needs to be a process that will continuously capture these changes. NPCC is of the opinion that the NERC Standards are living documents and are the best mechanism available to the industry for capturing these changes by the continuous updating of the standard's requirements included within.
It is to too early in the process to identify whether there will be a need for a regional variance or business practice to consider with this SAR. NPCC believes that it is premature to either determine or conclude that an impact will exist in the future.
NPCC believes that this SAR serves as only a beginning for addressing Real Time Tools and should not be construed as all encompassing. What is the intention for addressing the input devices for these tools (i.e.--current transformers, potential devices, transducers)?
Group
Public Service Enterprise Group Companies
Yes
PSEG agrees that these items require a standard. However, creating a new standard for telemetry or other items may duplicate or conflict with what is in standards COM-001 & COM-002. The scope of this SAR should be expanded to include potential revisions to COM-001 and COM-002 to ensure that all three standards are complementary and consistent.
No
The scope of this SAR should be expanded to include potential revisions to COM-001 and COM-002 to ensure that all three standards are non-duplicative, complementary and consistent.
Yes
The SAR should be limited to the "what" and not include the "how." There are multiple equally effective ways of accomplishing the "how" and the decision as to which to use should be left to the impacted registered entities.
No
If the scope of this SAR is expanded to include potential revisions to COM-001 and COM-002 to ensure that all three standards are non-duplicative, complementary and consistent, then PSEG concurs that alarming, telemetry and network analysis are the right set of functions.
Yes
No
If "real-time" is redefined in the NERC glossary, it will be necessary to analyze the impact of this definitional change in each of the over 100 usages of this term throughout the full body of standards. If there is a particular concern about the speed/accuracy of "real-time" for this standard, then the specific requirement should be specified in this standard and not as a general definitional change.
No
Generator Operators do not fit within the scope of this standard. They do not have direct involvement in the matters covered by this SAR. Any necessary GOP actions or requirements would be covered in the interconnection or operating agreements between generators and the applicable entities.
Reliability Standard

While PSEG is not aware of the specific need for a regional variance or business practice, the SAR should specify that the drafting team should consider and give deference to the long-standing requirements of RTOs and ISOs (as RC, BA, and TOP) that have maintained exemplary high levels of reliability in their areas. These RTOs and ISOs have a primary obligation to maintain reliability, and through extensive experience have mandated what real time tools are necessary to this end in their areas. For instance, PJM Manual 1 Control Center and Data Exchange Requirements provides examples of many existing requirements for real time tools, including telemetry, alarms, assurance of date integrity, etc. The drafting team should be encouraged to make use of these existing resources and ensure that the new standard does not conflict with what has proven in practice to work well.

See comments to Questions 5 & 8.
Yes
No
The SERC OC Standards Review Group supports placing any requirements related to this SAR in the Certification process. As such, this conversation is premature at this time, and should be held with the industry when the final location of these requirements is decided. It is unclear at this time how performance metrics would be tracked or enforced if the requirements become certification requirements.
No
NERC should proceed only with extreme caution when "redefining" a commonly understood industry term. If there is a need to define a new concept that is somewhat close to the meaning of Real-time, NERC should label that concept something other than Real-time. Because the term "Real-time" is commonly understood in the industry, the definition for Real-time in the NERC Glossary could be deleted. As auditing staff attempts to assess compliance with requirements during a future audit, it should not have to determine the vintage of a definition that helps explain the intent of a requirement.
No
If a need later develops to make the GOP applicable, then a SAR could be generated to cover the GOP at that time
Certification Process
First and foremost, the requirements developed as a part of this SAR must focus on capability, not specific technologies. The BES must not follow the path of the nuclear industry which suffers today from having specific technologies designated in the plant design basis. Technologies are progressing faster than a requirements process can follow. Embedding a specific tool in certification also creates measurement difficulty as the state of the art advances, which further supports our assertion that specifying capability rather than technology is the correct approach.
Neither is applicable. The reliability of the BES is only as good as the weakest link, therefore, no variances should be allowed.
Individual
Kathleen Goodman
ISO New England Inc.
No
The specific tools used in Operations must be designed for and by the entity using those tools to meet NERC standards. NERC standards define the system performance expected of the entity. The standards should NOT also impose constraints on the tools and the characteristics and performance requirements of those tools that are used by the entity to meet the expected system performance.
No
The SAR scope while limiting itself to Alarming, Telemetry and Network Analysis does not excuse the fact that operational tools and their characteristics should NOT be mandated by NERC standards. Mandating tools and their characteristics will stifle innovation and will overlook the local characteristics that must be addressed by the affected entities; and can impact Market structures and integration of renewal resources and adoption of smart grid devices.
No
The IRC does agree with the principle that NERC standards should define "What" not "How". However, by defining the characteristics of alarms, of telemetry and of Network Analysis, this SAR will be defining the HOW of an entity alarming, metering and analyzing its system. It seems obvious that analytic tools used to analyze a small co-op would be quite different from the analytic tools needed used to analyze a large RTO. The tools needed to analyze a stable/fixed load area would be quite different from a system with highly varying loads. The proposed standards will either create large inefficiencies for the smaller entity, or the standards will create inadequate

requirements for the larger entity.
No
See responses above.
No
Metrics of tool performance may sound like a great idea, however such standards will create a environment where tool characteristics become a goal unto itself, as opposed to an environment where ensuring transmission system reliability is the goal. NERC standards should be written to drive proper behavior and stipulate specific performance level of an entity to perform the tasks associated with the function it registers as. Those standards do not excuse that entity because the primary tool the entity uses is not available. Today's standards impose an implied obligation to have redundant / back-up tools to ensure that system reliability is maintained, regardless of tool's capability and availability in use. Tool metrics will create needless penalties, and are not drivers for proper behavior to ensure reliability. If a tool does not perform as this proposed SAR mandates, then the entity will be assessed non-compliant EVEN THOUGH the entity is meeting the primary goal of maintaining reliability. Tool unavailability is not the same as transmission performance problems. Bad tools do not equate to a bad behavior or system performance. The SRC would also note that there are currently requirements to ensure that tools are maintained and properly managed (see CIP-007 and IRO-002 R9). This suffices to ensure that the responsible entity has the needed tool capability to perform its tasks.
No
This proposal will more likely cause unintended consequences. The SAR requestor states that the redefinition is needed because of inherent time-delays in data. The outcome of a strict definition could be that all data must be sampled at the same universal time. The result of such a noble idea would be to impose unjustified costs on every entity in North America. These costs will result because not every point can be obtained at the exact same time unless the requesting entity has a huge capability to gather data simultaneously. A likely result of such standards will be unbundling responsibility into smaller entities. That in turn will result in less than wide-area analysis. That in turn will result in a less reliable bulk power system.
This question is unclear because the GOP is an applicable entity for NERC standards. Does a GOP need to do Network Analysis? If that is the question, the answer is NO; a GOP must operate a Generator, the TOP / RC must do the transmission analysis. Equally inappropriate would be to impose a mandate that the analysis tools on nuclear units have the same characteristics as the analysis tools on a CT.
Certification Process
First of all, we do not agree with creating a standard for tool characteristics or performance levels. If monitoring, alarming and analysis capabilities of an entity need to be specified and complied with, then we'd suggest that the certification process be used with the certification scope and requirements so clearly stipulated that the entity must demonstrate it has acquired such capabilities to perform the assigned tasks. The capability requirements are "one of" assessment. As such, they should be a part of the certification process, not an on going assessment of proper behavior or performance level of an entity which are is more suited in a standard.
There are numerous existing requirements for the RC, TOP, and BA to perform analysis and studies. Having these studies performed with what works best for the individual entity is important for reliability, not how they performed the study and analysis. The goal of a solid NERC Standard should be focused on the outcome.

Reliability Standard
The Final report from the given link is missing the detailed data sections (everything after the introductions page 36). This requires minimum standards for tools - this is GOOD to have and the tools should be used. There should be a recognition of the effort to keep some of the tools working. Some of the requirements are overly prescriptive - not necessary with respect to external Interchange data. Not enough discrimination between primary entity EMS communication and ICCP exchange with external entities, which are mostly indirect reliability issues. There should be allowance for maintenance of the equipment: primary and secondary. The ICCP is sometimes handled over communications paths not under maintenance control of the TOP/BA. Sometimes equipment may break in unusual ways and take longer to diagnose and repair than the proposed criteria allowances would allow. Diagnosing the state estimator failure takes more time than the proposed criteria allows. The criteria is unrealistic in not recognizing that, as well as the orders of magnitude for a number of additional telemetered points required to reduce it. It's good to have frequent solutions, but it's not necessary to "measure it" and to penalize if it doesn't while diagnosing the trouble. This requires an increase in 24/7 staff to manage to the proposed criteria, but still takes time to diagnose/correct failed solutions. The contingency criteria is dependent on the state estimator, so there could be double jeopardy on proposed violations.

Yes
Yes
Yes
It is very important that we focus on the "what" and not the "how". Smaller systems can easily meet the functionality requirements of an eventual standards without the need for expensive additional software.
No
The proposed functions do not seem to address the "visualization" over a wide geographic area aspect of blackout recommendations. "Visualization" probably ought to be added as a function applicable to Reliability Coordinators.
No
The proposed metrics are primarily very IT system focused metrics that may not be directly correlated with the reliability of the Bulk Electric System. The metrics ought to be focused more on what is important to reliable operations, such as accuracy of information, timeliness of information, etc. If you think of it, in order to have accurate and timely information, an IT systems will need to be available, maintenance will have to have been coordinated, etc. The metrics proposed lean towards "how" and not "what".
Yes
The definition would go hand in hand with a key metric for the standard that probably ought to be added, timeliness of information. E.g., if a Transmission Owner is using a 10 minute rating for a line and it takes 5 minutes for the operator to even receive information that the line is beyond its normal rating, then the operator really only has about 5 minutes to make a decision and take action to reduce the loading on the line. Obviously, the more time the operator has to make decisions and take action in a deliberate fashion, the more reliable the power system. One key way to do this is to define "real-time" with a reasonable time delay maybe 3 minutes.
No

Why would a GOP have need for this? Most GOPs are radial to the interconnection point, so a contingency analysis will reveal nothing. The TOPs and RC will already be including the loss of generation or other contingencies in their contingency analysis. The only real involvement with the GOP is their metering and RTUs if the TOPs, BAs and RCs are depending on the GOPs information as data points in the control systems. There could be a requirement that the GOPs provide data to the TOPs / BAs / RCs through metering, RTUs and communication links to the TOPs / BAs / RCs criteria, but that should be the extent of what is required of GOPs, and, if that is a requirement of GOPs, then we would seriously need to consider LSEs and DPs as applicable entities to receive accurate load, losses and power factor information. This sort of requirement, however, probably belongs in the COM standards.
Reliability Standard
Not aware of any.
Please do not confuse the roles of TOPs, BAs and RCs. A BA should not be required to have a contingency analysis tool of transmission lines since that is not their function. A TOP should not be required to monitor supply and demand balance since that is not their function. Clearly delineate what is required of each entity.

Yes
Yes
We agree with this approach and we encourage the SAR and subsequent effort of the SDT to focus on the minimum requirements (tools) needed to provide an Adequate Level of Reliability (ALR). The standard(s) should be careful to avoid prescriptive language that mandates the use of what could be considered cutting edge technologies that would cause inefficient use of limited resources.
Yes
Yes
Yes
We agree with the SAR's recommendation to revisit the definition of Real-time. However, if revised, the SDT should carefully consider any unintended impacts a change in definition may have on other existing reliability standards that reference the existing term.
Yes
An SDT should always have the freedom to consider new or revised applicability in standards projects in an effort to enhance the Adequate Level of Reliability of the BES. However, in the case of this project, applicability to requirements related to real-time operating tools should only be considered for Generator Operators (GOP) with centrally located dispatch or control centers with control over multiple generation plants. The requirements must not apply to GOP located within a control room having responsibility for only a unit(s) located at a single plant location. Also, if the GOP is retained as a reliability function within the scope of this SAR, the SAR's Purpose statement should be revised to include a reference to and discussion regarding the intent of adding the GOP as an applicabe entity. Furthermore, there should be no expectation that a GOP would be performing network analysis of the BES and the standard(s) should be clear that those tools remain with the RC and TOP.
Reliability Standard
We are not aware of any.
1. This SAR should be careful to avoid development of redundant requirements that describe the tasks performed by responsible entities that rely upon the real-time tools. There are a number of existing standards with requirements already aimed at addressing alarming, telemetry, and network analysis within the BAL, COM, IRO, and TOP family of standards. To the extent the drafting team considers putting end-result expectations within new real-time tools standard(s) as proposed

by this SAR, these existing requirements should also be reviewed to consider moving them to the new standard(s). Alternatively, in lieu of creating new standard(s), the existing standards mentioned above could be considered for revision to describe the minimum technical expectations and management of the real-time tools as proposed by this SAR. 2. This SAR appears to be sharply focused on addressing aspects of alarming, telemetry and network analysis. The SAR DT should consider the May 5, 2009 report provided by the Chair of the NERC Operating Committee (OC), Gayle Mayo, titled "Operating Committee Report to Board of Trustees Technology Committee: Management of NERC Reliability Tools". The OC's report describes real-time tools that NERC manages that are relied upon by registered entities and the potential conflict of NERC managing the tools while also having responsibility for enforcing compliance enabled by the tools. The interim proposed solution recommended to establish a joint industry/NERC management group as an independent arm of NERC reporting to the NERC BoT. To the extent any of the reliability tools described in the OC's report have bearing on the focus of this SAR, it may be necessary to include requirements within the proposed standard(s) to adequately cover the OC's vision and responsibility of the proposed independent real-time tools management group. Additionally, the SAR DT should consider if applicability changes are needed within the proposed standard(s) to address the OC's proposal.
Individual
Julie Reichle
NorthWestern Energy
No
NorthWestern Energy agrees that there is a reliability-related need for proposed guidelines pertaining to alarming, telemetry, and network analysis. However, a proposed standard should only come after guidelines and criteria have been tested during a trial period. This way the feasibility or functionality of the established guidelines, for Real-time tools, can be tested and proven to be effective before a sanction standard is put in place.
No
NorthWestern Energy agrees that the scope of the SAR has merit for establishing guidelines, but not for developing a new standard. The functionality, performance, and management of Real-time tools for Reliability Coordinators, Transmission Operators, and Balancing Authorities need guidance and direction. However, the proposal for a new standard should be prolonged until reliability entities can implement real time practices, put forth from guidelines, and truly test the feasibility, functionality, performance, and management of Real-time tools
No
NorthWestern Energy agrees with this approach but not for the proposal/request of a standard. Guidelines that describe what needs to be done for the functionality, performance, and management of Real-time tools should be established for Reliability Coordinators (RC) first. Once a test and evaluation period is complete, then a new standard should be proposed for Transmission Operators (TOP) and Balancing Authorities (BA) with proper guidelines for implementation. RCs have the highest authority and wide area view of Interconnections, so it seems logical that new guidelines in this area should begin at the RC level first.
No
NorthWestern Energy agrees with the focus on alarming and telemetry for all three of the reliability entities mentioned (Reliability Coordinators, Transmission Operators, and Balancing Authorities). The focus on network analysis should only apply to RCs first and then to TOPs and BAs. Northwestern Energy would also recommend having alarming for telemetry data only. Northwestern energy would not recommend replacing real-time alarming values with state estimated values. Again here NorthWestern Energy believes that the focus on alarming, telemetry, and network analysis should begin with guidelines and criteria before a standard is proposed/requested.
No
Northwestern Energy agrees with the performance metrics; however the whole set will be applicable only for alarming and telemetry purposes. Furthermore, the metrics need to be tested and evaluated before a standard can be requested.
Yes
Northwestern Energy believes that a new definition which explains more about what is expected out of “Real Time” is needed. The current definition is vague and broad, a more defined timeframe would provide better operating criteria and guidelines to Reliability Coordinators, Transmission

Operators and Balancing Authorities
Yes
NorthWestern Energy agrees that a potential Standards Drafting Team should have the freedom to consider the GOP as an applicable entity. However, close consideration should be given to the NERC Functional Model to ensure that the focus of the proposed standard truly applies to a GOP or any NERC Registered Entity. Furthermore, the final decision on this matter should still reside with NERC.
Reliability Standard
Northwestern Energy would recommend putting it as a Reliability Standard only after it has been tested and proven to be effective, then the requirements can be recognized as a Reliability Standard.
Business Practice
Northwestern Energy would recommend implementing this only for RCs to test the feasibility and functionality of the established guidelines on a trial period. If the guidelines prove to be effective then it can be implemented for TOPs and BAs with detailed operational guidelines.
As mentioned in the Real-Time Tools Survey Analysis and Recommendations Final Report (dated March 13, 2009), "RTBPTF believes that mandatory requirements for real-time tools for reactive reserve monitoring would be highly desirable; however, before such recommendations can be formulated, NERC must define technically justified and feasible-to-implement requirements for determining the appropriate amount and location of acceptable reactive reserves and clarifying how reliability coordinators should monitor these reserves." NorthWestern Energy believes that the same should hold true for alarms, telemetry, and network analysis. First guidelines, in these areas, should be established by NERC; then once implemented and proven effective by Reliability Coordinators these guidelines can be passed down to Transmission Operators and Balancing Authorities.
Individual
Brian Evans-Mongeon
Utility Services LLC
No
Standards will likely end up complicating the work of the real time operators. It will be impossible to devise tools that can deal with every possible scenario a RT operator will encounter. RT operators have been trained to assess the conditions at the time of the event or disturbance and to take all appropriate actions necessary to correct the condition.
No
Yes
When appropriate, standards should never prescribe how.

Based on the NERC BOT approval of PER-005-1, System Personnel Training, with a purpose of "To ensure that System Operators performing real-time, reliability-related tasks on the North American Bulk Electric System (BES) are competent to perform those reliability-related tasks. The competency of System Operators is critical to the reliability of the North American Bulk Electric System". The need for awareness as described by the RTBPTF in their 13 March 2008 report will be satisfied by RCs, TOPs, and BAs using a systematic approach to training to establish a training program for the BES company-specific reliability-related tasks performed by its System Operators. By using PER-005's systematic approach to training, the process of ensuring system operator training needs never stops. All tasks will be required to be evaluated. In the detailed Description of the SAR it is proposed that Alarming, Telemetry and Network analysis is developed into a standard. These three functions are what system operators are already performing on a daily basis as described in the following Commission approved NERC Standards. IRO-002-1, R2 states, "Each RC shall determine the data requirements to support its reliability coordination tasks…" IRO-002-1, R5 states, "Each RC shall have detailed real – time monitoring capability…" IRO-002-1, R6 states, "Each RC shall monitor Bulk Electric System elements…" TOP-006-1, R1 states, "Each TOP, BA shall know the status of all generation and transmission resources available for use." TOP-006-1, R2 states, "Each RC, TOP, and BA shall monitor applicable transmission line status, real and reactive power flows, voltage, load tap changer settings, and status of rotating and static reactive resources". TOP-006-1, R4 states, "Each RC, TOP, and BA shall have information, including weather forecasts and past load patters, available to predict the system's near tern load pattern". TOP-006-1, R5 states, "Each RC, TOP, and BA shall use monitoring equipment to bring to the attention of operating personnel important deviations in operating conditions and to indicate, if appropriate, the need for corrective action". TOP-008-1, R2 states, "Each TOP shall operate to prevent the likelihood that a disturbance, action, or inaction will result in an IROL or SOL violation…". TOP-008-1, R4 states, The TOP shall have sufficient information and analysis tools to determine the cause(s) of SOL violations".
No
Is the scope of this SAR to make operators aware of the alarms? Keep close to the practices of the recommendations of the Blackout report. Some type of caution should be expressed in that entities should not be told how to operate or address their alarms. A guideline would be more appropriate for this proposed standards action. The operating environment should focus on reliable system operation and focus for the system operation staff. For example the size of the entity's system or how the entity is structured will vary the type of the tools used and would make it difficult to make a one-size fits all standard. There is concern that the SAR may be expecting research and development of tools. This is not an appropriate use of a SAR.
Yes
This approach is stated on page 29 of NERCs "Drafting Team Guidelines". The Drafting Team must follow the guideline of establishing the "what" criteria for each requirement.
No
Each RC, TOP, and BA will have a different set of needs based on System Operator experience. This is why alarming, telemetry and network analysis should be training requirements, not a new standard. When a RC, TOP, and BA follow the systematic approach to training, these items should be part of the company's reliability - related task list. It is also not clear as to how far reaching standards for these functions would be. For example, MRO NSRS would not be in support of

anything that would infer the need to install duplicate instruments to provide information to a Reliability Coordinator (as in most cases this data is acquired by the TOP and BA and then passed to the RC).
No
Are the above metrics for the functions of Alarming, Telemetry, and Network analysis? A metrics is simple standard of measure. MRO NSRS understands that a metrics can be used in a measurement of a quantitative action, but how it would be used during "current operations" is not apparent. Perhaps this SAR should be more System Operator training based. If metrics were to be developed, any requirements created to impose metrics should allow for exceptions for extended outages of equipment for uncontrollable reasons. As written in the recommendation report, an outage on a real time tool for as short as a few hours could create significant non-compliance events, while not having any impact to the reliability of the system.
No
The current definition as listed in the NERC glossary is adequate. Real-Time is an understood concept within the industry.
No
A GOP follows dispatch instructions from a BA or prior committed schedule and will be held accountable if those instructions are not followed. There is no need to have GOPs within this SAR.
Certification Process
Please describe what the certification process is? Would this be for entities who wish to be registered as a BA, RC or TOP? Perhaps NERC could formulate a training program concerning these issues and give it to "all" entities to incorporate into their training programs. It would make a bigger impact vice having this SAR (and later proposed standard) be pushed around for many years before the Commission ever see it. If this is an Event recommendation, and it has taken 4 years to get a SAR, we have one slow process. Hire a contractor, put together a program based on the RTBPTF recommendations and allow All NERC Registered entities to train on it.
Business Practice

Derek Bleyle
South Carolina Electric and Gas
Yes
Yes
Yes
Yes
Yes
While we agree that the performance metrics should be part of the Standard, these metrics must allow for some level of equipment failure, communication failure, etc. and should not be a 100% performance requirement.
Yes
However, it should be noted in the Standard that there is an inherent delay in data acquistion, data processing, and data analysis. As such, things are not measured or calculated in real time per se, but are done as close to real time as practically possible. It should also be noted that caution should

be used if this term is re-defined as this is a commonly used and understood industry term.
No
The difference between a reliability standard and certification process needs to be clarified by NERC before this question can be answered.
Individual
Catherine Koch
Pugets Sound Energy
Yes
Yes
The SAR indicates it address selected recommendations in the RTBPTF Report. It appears the focus from the report is on 1. Reliability Toolbox and not recommendations listed in 2. Enhanced Operator Situational Awareness or 3. Address Six Major Issues to enhance the effectiveness of real-time tools which we would agree with at this time.
Yes
PSE suggests caution in defining "what" needs to be done if it leads to "how much" needs to be installed. An over abundance of telemetry data and alarms can create complexity when responding to an event and must be displayed effectively to be valuable.
Yes
No
Availability and quality appear to be performance metrics. Change management, maintenance coordination, and failure notification do not seem to be performance metrics as stated. These may also overlap significantly with the CIP standards and should be aligned effectively.
Yes
Suggest aligning with the Real Time Operations Time Horizon for which each requirement is assessed relative to a violation. This would ensure no confusion.
Yes
However, we suggest considering application of any of these standards is relative to the existance of a control center as defined or intended by the CIP standards. This would not impose an unnecessary burdan.
Reliability Standard
Individual
Jason Marshall
Midwest ISO
Yes
Midwest ISO supports the proposed standard to develop "requirements for the functionality, performance and management of Real-Time tools for Reliability Coordinators".
Yes
Yes
The Midwest ISO agrees the SAR should focus on "what" and not "how".
Yes
Yes
We largely agree with the need for the performance metrics; however, we caution the drafting

team to avoid duplicating already existing similar requirements. IRO-002 R9 already requires the RC to have approval for tool outages. CIP-007 already requires a change management process.
No
There does not appear to be any compelling reason to change the definition. It is likely any changes will only cause confusion.
No
There is no need to include the GOP. The GOP clearly has no need for network analysis capabilities.
Reliability Standard
The Midwest ISO believes the drafting team may need to develop both Reliability and Certification standards. Unfortunately, both options could not be selected.
The Midwest ISO believes this SAR and resulting standard should address what is required in terms of backup tools or more conservative operations when a tool is unavailable because no tool has 100% availability.
Group
IRC Standards Review Committee
No
The specific tools used in Operations must be designed for and by the entity using those tools to meet NERC standards. NERC standards define the system performance expected of the entity. The standards should NOT also impose constraints on the tools and the characteristics and performance requirements of those tools that are used by the entity to meet the expected system performance.
No
The SAR scope while limiting itself to Alarming, Telemetry and Network Analysis does not excuse the fact that operational tools and their characteristics should NOT be mandated by NERC standards. Mandating tools and their characteristics will likely stifle innovation and will overlook or otherwise fail to consider the variations in the local characteristics that must be addressed by the affected entities; and can impact Market structures, integration of renewable resources, and adoption of smart grid devices.
No
The IRC does agree with the principle that NERC standards should define “What” not “How”. However, by defining the characteristics of alarms, of telemetry and of Network Analysis, this SAR will be defining the HOW of an entity alarming, metering and analyzing its system. It seems obvious that analytic tools used to analyze a small co-op would be quite different from the analytic tools needed to analyze a large RTO. The tools needed to analyze a stable/fixed load area would be quite different from a system with highly varying loads. The proposed standards will either create large inefficiencies for the smaller entity, or the standards will create inadequate requirements for the larger entity.
No
See responses above.
No
Metrics of tool performance may sound like a great idea, however such standards will unintentionally create a environment where tool characteristics become a goal unto itself, as opposed to an environment where ensuring transmission system reliability is the goal. NERC standards should be written to drive proper behavior and stipulate specific performance level of an entity to perform the tasks associated with the function for which it is registered. Those standards do not excuse that entity because the primary tool the entity uses is not available. Today’s standards impose an implied obligation to have redundant / back-up tools to ensure that system reliability is maintained, regardless of tool’s capability and availability in use. Tool metrics will create needless penalties, and are not drivers for proper behavior to ensure reliability. If a tool does not perform as this proposed SAR mandates, then the entity will be assessed non-compliant EVEN THOUGH the entity is meeting the primary goal of maintaining reliability. Tool unavailability is not the same as transmission performance problems. Bad or malfunctioning tools, in themselves, do not equate to a bad behavior or system performance. The IRC would also note that there are currently requirements to ensure that tools are maintained and properly managed (see CIP-007 and IRO-002 R9). This suffices to ensure that the responsible entity has the needed tool capability to perform its tasks.

No
This proposal will more likely cause unintended consequences. The SAR requestor states that the redefinition is needed because of inherent time-delays in data. The outcome of a strict definition could be that all data must be sampled at the same universal time. The result of such a noble idea would be to impose unjustified costs on every entity in North America. These costs will result because not every point can be obtained at the exact same time unless the requesting entity has a huge capability to gather data simultaneously. A likely result of such standards will be unbundling responsibility into smaller entities. That in turn will result in less than wide-area analysis. That in turn will result in a less reliable bulk power system.
This question is unclear because the GOP is an applicable entity for NERC standards. Does a GOP need to do Network Analysis? If that is the question, the answer is NO; a GOP must operate a Generator, the TOP / RC must do the transmission analysis. Equally inappropriate would be to impose a mandate that the analysis tools on nuclear units have the same characteristics as the analysis tools on a CT.
Certification Process
First of all, we do not agree with creating a standard for tool characteristics or performance levels. If monitoring, alarming and analysis capabilities of an entity need to be specified and complied with, then we'd suggest that the certification process be used with the certification scope and requirements so clearly stipulated that the entity must demonstrate it has acquired such capabilities to perform the assigned tasks. The capability requirements are "one of" assessment. As such, they should be a part of the certification process, not an on going assessment of proper behavior or performance level of an entity which is more suited in a standard.
None
There are numerous existing requirements for the RC, TOP, and BA to perform analysis and studies. Having these studies performed with what works best for the individual entity is important for reliability, not how they performed the study and analysis. The goal of a solid NERC Standard should be focused on the outcome.
Individual
Dan Rochester
Independent Electricity System Operator
No
Tools used in Operations should be designed for and by the entity using those tools to meet NERC standards. NERC standards should stipulate the requirements that drive proper behavior and system performance expected of the entity. The standards should NOT also impose constraints on the tools and the characteristics and performance requirements of those tools that are used by the entity to meet the expected system performance.
No
Mandating tools and their characteristics will stifle innovation and will overlook the local characteristics that must be addressed by the affected entities, and can impact market structures and integration and management of other emerging issues such as renewal resources and adoption of smart grid devices.
No
We support the principle that NERC standards should define the "What" not the "How". However, by defining the characteristics of alarms, of telemetry and of Network Analysis, this SAR will be defining the HOW of an entity will alarm, meter and analyze its system. The "what", in our view, will be an entity's capability to monitor and analyze the power system and respond to alarmed situations. We do not think that a standard that stipulates the characteristics and performance level of tools is necessary.
No
We do not agree with the need for such a standard.
No
NERC standards should be written to drive proper behavior and stipulate specific performance level of an entity to perform the tasks associated with the function it registers as. Such standards should not excuse that entity for non-compliant because the primary tool the entity uses is not available. Today's standards impose an implied obligation to have redundant / back-up tools to ensure that system reliability is maintained, regardless of tool's capability and availability. Tool metrics will create unnecessary requirements and penalties, and are not drivers for proper behavior to ensure

reliability. If a tool does not perform the requirements that this proposed SAR mandates, then the entity will be assessed non-compliant even though the entity may be meeting the primary goal of maintaining reliability. We would also note that there are currently requirements to ensure that tools are maintained and properly managed (see CIP-007 and IRO-002 R9). This suffices to ensure that the responsible entity has the needed tool capability to perform its tasks.
No
This proposal will more likely cause unintended consequences. The SAR suggests that a redefinition is needed because of inherent time-delays in data. The outcome of a strict definition could be that all data must be sampled at the same universal time. The result of such a noble idea would be to impose unjustified costs on every entity in North America. These costs will result because not every point can be obtained at the exact same time unless the requesting entity has a huge capability to gather data simultaneously. A likely result of such standards will be smaller entities. That in turn will result in less than wide-area analysis. That in turn will result in a less reliable bulk power system. Real time operation is generally understood to be now and the next several minutes up to an hour. Any attempt to redefine the term Real Time to suit the purpose of tool characteristics or requirements will introduce problems or serious implications to the requirements governing real time operations.
This question is unclear because the GOP is an applicable entity for NERC standards. Does a GOP need to analyze the network performance? If that is the question, the answer is NO; a GOP needs only operate a generator, the TOP / RC must conduct network analyses.
Certification Process
First of all, we do not agree with creating a standard for tool characteristics or performance levels. If monitoring, alarming and analysis capabilities of an entity need to be specified and complied with, then we'd suggest that the certification process be used with the certification scope and requirements so clearly stipulated that the entity must demonstrate it has acquired such capabilities to perform the assigned tasks. The capability requirements are "one of" assessment. As such, they should be a part of the certification process, not an on going assessment of proper behavior or performance level of an entity which are more suited in a standard.
No
There already exist a number of standard requirements for the RC, TOP, and BA to conduct analyses and studies. Having these studies performed with what works best for the individual entity is essential for reliability, not how they performed the study and analysis.
Individual
Michael Gammon
Kansas City Power & Light
No
No. It is not the place for requirements and standards to dictate tools to operating entities. Standards and requirements are to specify what should be done for reliability not how to do it. The report is excellent as a best practices for the industry and should be left at that.
No
Yes
No
Operational situational awareness is a very complex mix of tools and displays of graphical and tabular information. It will be an extraordinarily difficult effort for a standard to capture that mix. The current standards and requirements that require sufficient monitoring, outage coordination, outage evaluation, mitigation plans for extreme operating conditions, etc. taken all together form a comprehensive assemblage of reliability principles that are sufficient to address the concerns of the August 14 black-out report.
No

Consideration of Comments on Project 2009-02 — SAR for Real-time Reliability Monitoring and Analysis Capabilities

The Real-time Reliability Monitoring and Analysis Capabilities SAR Drafting Team (RTT SAR DT) thanks all commenters who submitted comments on the first draft SAR. The SAR was posted for a 30-day public comment period from June 10, 2009 through July 11, 2009. The stakeholders were asked to provide feedback on the documents through a special Electronic Comment Form. There were 42 sets of comments, including comments from more than 100 different people from over 60 companies representing 9 of the 10 Industry Segments as shown in the table on the following pages.

The SDT has made numerous changes to the content of the SAR in an attempt to provide clarity to the SDT's position. This SAR is not about the Real-time Tools Best Practices Task Force Report nor is it about tools in general. It is about capabilities that functional entities must have in order to do their appointed tasks. The SAR DT does not contemplate naming specific tools or in telling functional entities how to do their jobs; the SAR is about the performance and capability of any tools utilized in the process of doing that job. The changes to the SAR are designed to bring those points across. Indeed, the SAR has been re-named to avoid any confusion with tools.

Due to the number of comments received and the apparent confusion about the intent of the SAR, the SAR DT has revised the language of the SAR to provide clarity and is requesting a second posting of this SAR.

This report includes all comments, re-sorted to make them easier to interpret; stakeholders can go the following location where they can read the submitted comments on the original Comment Forms.

http://www.nerc.com/filez/standards/Project2009-02_Real_Time_Tools.html

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process! If you feel there has been an error or omission, you can contact the Vice President and Director of Standards, Gerry Adamski, at 609-452-8060 or at gerry.adamski@nerc.net. In addition, there is a NERC Reliability Standards Appeals Process.[1]

[1] The appeals process is in the Reliability Standards Development Procedures: http://www.nerc.com/standards/newstandardsprocess.html.

1. Do you agree that either there is a reliability-related need for the proposed standards action?

Summary Consideration: There were three main themes expressed in the comments: (1) certification vs. standards; (2) tools vs. functionality or 'what vs. 'how'; and (3) new standards vs. revision of existing standards.

1. Industry was divided on whether there was a reliability related need for the proposed standards action. Some commenters responded that they thought certification was a preferable approach versus standards. The SAR DT has discussed this at length and provided sound reasoning why certification may not be an acceptable solution as detailed in the individual responses below.
2. The SAR never cites a specific tool but focuses on the functionality required for Real-time monitoring and analysis. An entity could use any tool that it has at its disposal as long as it meets the functionality, performance, and management requirements to be determined by an eventual standard. The SAR explicitly focuses on 'what' and not 'how'.
3. The SAR has been expanded to allow the eventual SDT to make the decision as to whether to write new standards or revise existing standards.

The SAR is not the Real-time Tools Best Practices Task Force (RTBPTF) Report. Many of the recommendations of the RTBPTF Report were not included in the SAR. A study group handled the disposition of the recommendations in the RTBPTF Report and crafted the SAR to handle only those recommendations that were deemed appropriate for standards activity. The eventual SDT is not bound to replicate the recommendations of the RTBPTF; it will be bound by the language of the SAR.

Organization	Yes or No	Question 1 Comment
SERC OC Standards Review Group	No	See comments to Question 8.
E. On U.S.	No	See comments for Question 8
Entergy Services	No	Entergy supports the SERC OC comments.
Response: Please see response to question 8 comments.		
MRO NERC Standards Review Subcommittee	No	Based on the NERC BOT approval of PER-005-1, System Personnel Training, with a purpose of "To ensure that System Operators performing real-time, reliability-related tasks on the North American Bulk Electric System (BES) are competent to perform those reliability-related tasks. The competency of System Operators is critical to the reliability of the North American Bulk Electric System". The need for awareness as described by the RTBPTF in their 13 March 2008 report will be satisfied by RCs, TOPs, and BAs using a systematic approach to training to establish a training program for the BES company-specific reliability-related tasks performed by its System Operators. By using PER-005's systematic approach to training, the process of ensuring system operator training needs never stops. All tasks will be required to be evaluated.

Organization	Yes or No	Question 1 Comment
		In the detailed Description of the SAR it is proposed that Alarming, Telemetry and Network analysis is developed into a standard. These three functions are what system operators are already performing on a daily basis as described in the following Commission approved NERC Standards. IRO-002-1, R2 states, “Each RC shall determine the data requirements to support its reliability coordination tasks” “IRO-002-1, R5 states, “Each RC shall have detailed real “ time monitoring capability”“ IRO-002-1, R6 states, “Each RC shall monitor Bulk Electric System elements”“ TOP-006-1, R1 states, “Each TOP, BA shall know the status of all generation and transmission resources available for use.” TOP-006-1, R2 states, “Each RC, TOP, and BA shall monitor applicable transmission line status, real and reactive power flows, voltage, load tap changer settings, and status of rotating and static reactive resources”. TOP-006-1, R4 states, “Each RC, TOP, and BA shall have information, including weather forecasts and past load patters, available to predict the system’s near tern load pattern”. TOP-006-1, R5 states, “Each RC, TOP, and BA shall use monitoring equipment to bring to the attention of operating personnel important deviations in operating conditions and to indicate, if appropriate, the need for corrective action”. TOP-008-1, R2 states, “Each TOP shall operate to prevent the likelihood that a disturbance, action, or inaction will result in an IROL or SOL violation”“. TOP-008-1, R4 states, The TOP shall have sufficient information and analysis tools to determine the cause(s) of SOL violations”.
Response: The SDT does not see where the first paragraph contains any relevance to this SAR. An entity could have a training program but you could be missing essential functions. The SAR doesn’t mention training. The standards cited in paragraph 2 are being revised and many of the requirements cited are suggested for retirement with the understanding that this project (Project 2009-02) will take on that responsibility.		
IRC Standards Review Committee	No	The specific tools used in Operations must be designed for and by the entity using those tools to meet NERC standards. NERC standards define the system performance expected of the entity. The standards should NOT also impose constraints on the tools and the characteristics and performance requirements of those tools that are used by the entity to meet the expected system performance.
ISO New England Inc.	No	The specific tools used in Operations must be designed for and by the entity using those tools to meet NERC standards. NERC standards define the system performance expected of the entity. The standards should NOT also impose constraints on the tools and the characteristics and performance requirements of those tools that are used by the entity to meet the

Organization	Yes or No	Question 1 Comment
		expected system performance.
IESO	No	Tools used in Operations should be designed for and by the entity using those tools to meet NERC standards. NERC standards should stipulate the requirements that drive proper behavior and system performance expected of the entity. The standards should NOT also impose constraints on the tools and the characteristics and performance requirements of those tools that are used by the entity to meet the expected system performance.
Response: The SAR never cites a specific tool but focuses on the functionality required for Real-time monitoring and analysis. An entity could use any tools that they have at their disposal as long as they meet the functionality, performance, and management requirements to be determined by an eventual standard.		
American Transmission Company	No	ATC believes that this should be addressed in the certification process, and if necessary a re-certification process. If that effort fails to achieve the overall goal of this SAR, (Minimum types of Real-time tools) then we would be more open to a standards develop project.
Response: Certification is a one time process. New certification criteria do not apply to entities that have already been certified. There is no re-certification process nor are there any plans that the SAR DT is aware of to expand the certification process to include re-certification. Certification only proves that an entity had the functionality at a single point in time. There is no operational history associated with certification; therefore, certification criteria that deal with Real-time operations or data are only evaluated by the certification team to determine if the entity has adequate functionality to go operational. Certification relies on the Compliance Monitoring and Enforcement Program (CMEP) to prove compliance for this functionality on an on-going basis. However, CMEP can only evaluate compliance to requirements defined in the Reliability Standards. Therefore, the SAR is necessary to allow the creation of standard requirements to address the issues raised in the SAR so they will be evaluated by CMEP. Furthermore, there are 2 directives in FERC Order 693 relating to tool capability that need to be addressed. The existing projects that would have handled these issues (Project 2006-02 for IRO-002 and Project 2007-03 for TOP-006) have clearly indicated that they expect this SAR (Project 2009-02) to address the issues raised by FERC. It is difficult to perceive how any additions or changes to the certification process could come up with a solution that would satisfy and sustain a mandatory and enforceable status for those directives. Therefore, this SAR needs to move forward or the existing projects need to take back the responsibility for addressing the directives. The approach taken by the Standards Development Program is not to write new requirements that assess basic capabilities used to achieve performance measured through other requirements within the Reliability Standards. The SAR DT has researched the standards and concluded that other requirements do not presently exist to adequately cover the issues raised in the SAR. This SAR is the logical place and method for starting this process.		
CenterPoint Energy	No	CenterPoint Energy does not agree there is a reliability-related need for these proposed standards. The Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations reports on page 19 First Energy (FE) had state estimation and contingency analysis tools. The "tools were not used to assess system conditions, violating

Organization	Yes or No	Question 1 Comment
		NERC Operating Policy 5, Section C, Requirement 3, and Policy 4, Section A, Requirement 5. FE personnel did not ensure that their Real-Time Contingency Analysis (RTCA) was a functional and effective EMS application as required by NERC Policy 2, Section A, Requirement 1." CenterPoint Energy agrees that real-time monitoring and network analysis tools are necessary however, CenterPoint Energy believes the appropriate forum to evaluate an entities tools and their use would be during the certification process for a RC, BA, or TOP. Items such as functionality, performance, and management of the available tools as well as availability and quality of the entity's tools and how the entity uses the tools in their operation could be measured as well.
Response: Certification is a one time process. New certification criteria do not apply to entities that have already been certified. There is no re-certification process nor are there any plans that the SAR DT is aware of to expand the certification process to include re-certification. Certification only proves that an entity had the functionality at a single point in time. There is no operational history associated with certification; therefore, certification criteria that deal with Real-time operations or data are only evaluated by the certification team to determine if the entity has adequate functionality to go operational. Certification relies on the Compliance Monitoring and Enforcement Program (CMEP) to prove compliance for this functionality on an on-going basis. However, CMEP can only evaluate compliance to requirements defined in the Reliability Standards. Therefore, the SAR is necessary to allow the creation of standard requirements to address the issues raised in the SAR so they will be evaluated by CMEP. Furthermore, there are 2 directives in FERC Order 693 relating to tool capability that need to be addressed. The existing projects that would have handled these issues (Project 2006-02 for IRO-002 and Project 2007-03 for TOP-006) have clearly indicated that they expect this SAR (Project 2009-02) to address the issues raised by FERC. It is difficult to perceive how any additions or changes to the certification process could come up with a solution that would satisfy and sustain a mandatory and enforceable status for those directives. Therefore, this SAR needs to move forward or the existing projects need to take back the responsibility for addressing the directives. This SAR is the logical place and method for starting this process. .		
Xcel Energy	No	Several standards (IRO-002, TOP-006, TOP-008) already address the issues identified in this SAR. Rather than develop a new standard, we recommend evaluate or incorporate into an existing project for these standards.
Response: The SAR DT is not convinced that the cited standards truly address the issues of the SAR. It is possible that the eventual SDT could decide that the best method of solving the issue is to revise existing standards versus writing a new standard(s). To provide the eventual SDT with the greatest flexibility, the SAR DT has also checked the box for 'Existing Standard' as well as 'New Standard'.		
American Electric Power	No	AEP fully supports the need for entities to have an adequate tool set to operate in a reliable manner. However, it is AEP's belief that that reliability issues that this SAR intends to address are not resulting from a void in the reliability standards, but instead in the current certification processes. For example, some RTOs require that there are qualified systems in place prior to operating, while others require that individuals be certified. We would support that both elements are necessary, that is the right tool set verified and individuals having NERC certification, and that this occur in advance. Using the NERC certification process of functional entities to ensure that the right tool set is in place and operating correctly is preferable to allowing, by administrative registration alone, to begin operating and then, afterwards, try to invoke standards to address operating issues

Organization	Yes or No	Question 1 Comment
		that could have been avoided up-front. The certification process will need to also be modified beyond a single verification to a periodic process to ensure tools remain in place and are operating as expected.
Response: Certification is a one time process. New certification criteria do not apply to entities that have already been certified. There is no re-certification process nor are there any plans that the SAR DT is aware of to expand the certification process to include re-certification. Certification only proves that an entity had the functionality at a single point in time. There is no operational history associated with certification; therefore, certification criteria that deal with Real-time operations or data are only evaluated by the certification team to determine if the entity has adequate functionality to go operational. Certification relies on the Compliance Monitoring and Enforcement Program (CMEP) to prove compliance for this functionality on an on-going basis. However, CMEP can only evaluate compliance to requirements defined in the Reliability Standards. Therefore, the SAR is necessary to allow the creation of standard requirements to address the issues raised in the SAR so they will be evaluated by CMEP. Furthermore, there are 2 directives in FERC Order 693 relating to tool capability that need to be addressed. The existing projects that would have handled these issues (Project 2006-02 for IRO-002 and Project 2007-03 for TOP-006) have clearly indicated that they expect this SAR (Project 2009-02) to address the issues raised by FERC. It is difficult to perceive how any additions or changes to the certification process could come up with a solution that would satisfy and sustain a mandatory and enforceable status for those directives. Therefore, this SAR needs to move forward or the existing projects need to take back the responsibility for addressing the directives. This SAR is the logical place and method for starting this process.		
City of Tallahassee	No	While it should be mandatory for the RC's to have these reliability tools, it is a "best practice" for many of the TO's. For many other TO's it would be overkill to have to establish these programs for a relatively small area that is fed from only a couple of lines. How does the applicability change for the size of the organization? Standards should be the MINIMUM needed to operate reliably, not a culmination of the industries "best practices".
Response: The SAR doesn't mention specific tools but functionality. Applicability can be constrained by an eventual SDT but not by a SAR DT. If applicability should be constrained, it probably wouldn't be exclusively by size but on the importance to the reliability of the BES. Standards are neither a minimum nor a culmination of best practices but rather what is needed to reliably operate the BES.		
RRI Energy	No	For the RC, TOP and BA "Yes" in some fashion but the SAR should not be applicable to a GOP. The GOP is not a system operator at the same level as a RC, TOP and BA. We do not have the information on the real time status of the BES. We do not know transformer loadings (other than our GSU), transmission line loadings, generator status (other than our own) and details of demand (local load and projected load). GOP's by statute are prohibited from knowing this information. A standard is not needed to mandate that we have real time tools. The GOP's EMS has the necessary tools for the GOP to comply with the direction given them by the RC, TOP and BA. The GOP is required by the IA and market rules to follow the direction of the RC, TOP and BA. GOP is included as a System Operator but we believe that the definition should be modified. We plan to submit a SAR to request this change.
Response: The SAR DT understands that not all elements of the SAR would apply to a Generator Operator. By checking the box for Generator Operator, the SAR		

Organization	Yes or No	Question 1 Comment
DT is providing the eventual SDT with the flexibility to include a Generator Operator as an applicable entity if necessary. If the Generator Operator isn't checked off as an applicable entity in the SAR, the SDT does not have the flexibility to add them back in later if they are needed. However, if the Generator Operator is cited in the SAR and the SDT doesn't feel that they are needed in a standard, they can leave them off the list of applicable entities. For these reasons, the SAR DT feels that Generator Operators should continue to be listed as potential applicable entities in the SAR.		
NorthWestern Energy	No	NorthWestern Energy agrees that there is a reliability-related need for proposed guidelines pertaining to alarming, telemetry, and network analysis. However, a proposed standard should only come after guidelines and criteria have been tested during a trial period. This way the feasibility or functionality of the established guidelines, for Real-time tools, can be tested and proven to be effective before a sanction standard is put in place.
Response: The eventual SDT has the flexibility to ask that any standard or standard revision go through a field test prior to implementation. Any field testing would be appropriate after the requirements have been drafted and prior to implementation.		
Utility Services LLC	No	Standards will likely end up complicating the work of the real time operators. It will be impossible to devise tools that can deal with every possible scenario a RT operator will encounter. RT operators have been trained to assess the conditions at the time of the event or disturbance and to take all appropriate actions necessary to correct the condition.
Response: The SAR doesn't mention specific tools but functionality. An entity could have a training program but you could be missing essential functions.		
New Brunswick System Operator	No	NBSO does not believe that there is a reliability-related need for a standard specificaly for real time tools. Presently IRO and TOP standards address SOL and IROL awareness, detection and mitigation.
Response: The SAR doesn't mention specific tools but functionality. The standards cited are being revised and many of the requirements cited are suggested for retirement with the understanding that this project (Project 2009-02) will take on that responsibility.		
Kansas City Power & Light	No	No. It is not the place for requirements and standards to dictate tools to operating entities. Standards and requirements are to specify what should be done for reliability not how to do it. The report is excellent as a best practices for the industry and should be left at that.
Response: The SAR doesn't mention specific tools but functionality. The SAR only gets into 'what' and specifically and explicitly stays away from telling you 'how'. The SAR is not the report.		
Manitoba Hydro		While this project has value, it should fall very low on the list of priorities. Other standards with greater risk to the reliability of the BES should be reviewed and revised before starting any new project.
Response: The Standards Committee sets the priorities for standards projects. They will determine when this SAR moves to standard status if at all.		

Organization	Yes or No	Question 1 Comment
Duke Energy	Yes	However we are very concerned that the action to revise existing standards or develop new standards could be overly prescriptive. The requirements should remain at a high level, and focus on the "what", as opposed to the "how". The Introduction to the "Real-Time Tools Survey Analysis and Recommendations Final Report" contains 40 recommendations related to new or revised reliability standards; and we believe that many of these recommendations are too prescriptive to be placed in a reliability standard. This SAR should not become a project to implement all 40 of those recommendations. Additionally, we believe that many of these items more properly belong in an entity certification process and not in a Standard. The certification process should address core functionality tools. Standards should be used to address the operational application of these tools. See response to question #8.
Response: The SAR DT does not intend that any standard coming out of this effort be overly prescriptive but the eventual SDT will actually be writing the standard(s). The SAR clearly states that it is dealing with 'what' and not 'how'. The SAR is not dealing with all 40 recommendations of the report, just the items that are explicitly called out in the SAR. Certification is a one time process. New certification criteria do not apply to entities that have already been certified. There is no re-certification process nor are there any plans that the SAR DT is aware of to expand the certification process to include re-certification. Certification only proves that an entity had the functionality at a single point in time. There is no operational history associated with certification; therefore, certification criteria that deal with Real-time operations or data are only evaluated by the certification team to determine if the entity has adequate functionality to go operational. Certification relies on the Compliance Monitoring and Enforcement Program (CMEP) to prove compliance for this functionality on an on-going basis. However, CMEP can only evaluate compliance to requirements defined in the Reliability Standards. Therefore, the SAR is necessary to allow the creation of standard requirements to address the issues raised in the SAR so they will be evaluated by CMEP. Furthermore, there are 2 directives in FERC Order 693 relating to tool capability that need to be addressed. The existing projects that would have handled these issues (Project 2006-02 for IRO-002 and Project 2007-03 for TOP-006) have clearly indicated that they expect this SAR (Project 2009-02) to address the issues raised by FERC. It is difficult to perceive how any additions or changes to the certification process could come up with a solution that would satisfy and sustain a mandatory and enforceable status for those directives. Therefore, this SAR needs to move forward or the existing projects need to take back the responsibility for addressing the directives. The approach taken by the Standards Development Program is not to write new requirements that assess basic capabilities used to achieve performance measured through other requirements within the Reliability Standards. The SAR DT has researched the standards and concluded that other requirements do not presently exist to adequately cover the issues raised in the SAR. This SAR is the logical place and method for starting this process.		
Public Service Enterprise Group Companies	Yes	PSEG agrees that these items require a standard. However, creating a new standard for telemetry or other items may duplicate or conflict with what is in standards COM-001 & COM-002. The scope of this SAR should be expanded to include potential revisions to COM-001 and COM-002 to ensure that all three standards are complementary and consistent.
Response: The SAR DT does not believe that COM-002 is relevant to this SAR. However, COM-001 may be applicable. The SAR has been expanded to allow the		

Organization	Yes or No	Question 1 Comment
eventual SDT to make the decision as to whether to write new standards or revise existing standards.		
WECC Reliability Coordination	Yes	Our only concern is that the standard may outpace the available technology. Also, only tools that are applicable to all interconnections should be inlcuded in the standard.
Response: The SAR deals with functionality, not specific tools or technology. An eventual standard needs to cover more than just interconnections.		
Southern Company	Yes	In the absense of a certification process with re-certification, new standards should be established only if the same end can't be reached by revising existing standards. The RTBPTF's report gave several examples where real-time tools were mentioned but not well defined in existing standards. The SAR team should begin developing new standards only after they have determined that the same results can't be obtained by revising existing standards.
Response: The SAR has been expanded to allow the eventual SDT to make the decision as to whether to write new standards or revise existing standards. Certification is a one time process. New certification criteria do not apply to entities that have already been certified. There is no re-certification process nor are there any plans that the SAR DT is aware of to expand the certification process to include re-certification. Certification only proves that an entity had the functionality at a single point in time. There is no operational history associated with certification; therefore, certification criteria that deal with Real-time operations or data are only evaluated by the certification team to determine if the entity has adequate functionality to go operational. Certification relies on the Compliance Monitoring and Enforcement Program (CMEP) to prove compliance for this functionality on an on-going basis. However, CMEP can only evaluate compliance to requirements defined in the Reliability Standards. Therefore, the SAR is necessary to allow the creation of standard requirements to address the issues raised in the SAR so they will be evaluated by CMEP. Furthermore, there are 2 directives in FERC Order 693 relating to tool capability that need to be addressed. The existing projects that would have handled these issues (Project 2006-02 for IRO-002 and Project 2007-03 for TOP-006) have clearly indicated that they expect this SAR (Project 2009-02) to address the issues raised by FERC. It is difficult to perceive how any additions or changes to the certification process could come up with a solution that would satisfy and sustain a mandatory and enforceable status for those directives. Therefore, this SAR needs to move forward or the existing projects need to take back the responsibility for addressing the directives. The approach taken by the Standards Development Program is not to write new requirements that assess basic capabilities used to achieve performance measured through other requirements within the Reliability Standards. The SAR DT has researched the standards and concluded that other requirements do not presently exist to adequately cover the issues raised in the SAR. This SAR is the logical place and method for starting this process.		
NERC RTO SDT	Yes	The RTOSDT technically takes no position on the reliability need for requirements that state which specific tools are required, as we believe this to be the answer to the "how" question as opposed to the "what" question which is the nature of a true reliability requirement.

Organization	Yes or No	Question 1 Comment
Hydro One	Yes	From my travels and contacts I've witnessessed extreme variances in tool capability among control centres. A lack of standards has allowed companies to cut corners while others strive for excellence.
Midwest ISO	Yes	Midwest ISO supports the proposed standard to develop “requirements for the functionality, performance and management of Real-Time tools for Reliability Coordinators”.
Electric Market Policy	Yes	
Northeast Power Coordinating Council	Yes	
Pugets Sound Energy	Yes

Response: Thank you for your response.		

2. Do you agree with the scope of the proposed standards action?

Summary Consideration: The SAR DT has changed the title and wording of the SAR to clarify the intent. The SAR has also been revised to allow for the possibility of revising existing standards as opposed to writing new standards.

Organization	Yes or No	Question 2 Comment
Northeast Power Coordinating Council	No	The scope of the SAR is too "invasive" to operations. The SAR should address the "output" requirements for the hardware and software-- operators must be provided with the information "results" they need to know to determine how the system is behaving real time, and also for possible system configurations (e.g. contingency analysis). Even though in the Brief Description section of the SAR it states "The intent is to describe "what" needs to be done but not "how" to do it." the performance and management of tools falls into the "how" category. While NPCC suports the material in the RTBPTF Real-time Tools Survey Analysis and Recommendations report, the Standard should be limited to stating the reliability objectives of the Real-time Tools, leaving to each Registered Entity that must comply with the Standard the decision on how they are going to meet these objectives.
Response: The SAR DT believes that the SAR does address output requirements and reliability objectives. However, the wording may not be as clear as it could be. Therefore, the SAR DT has changed the language of the SAR text to bring greater clarity to this task. The SAR is explicit in stating 'what' and not 'how'.		
Public Service Enterprise Group Companies	No	The scope of this SAR should be expanded to include potential revisions to COM-001 and COM-002 to ensure that all three standards are non-duplicative, complementary and consistent.
Response: The SAR DT does not believe that COM-002 is relevant to this SAR. However, COM-001 may be applicable. The SAR has been expanded to allow the eventual SDT to make the decision as to whether to write new standards or revise existing standards.		
MRO NERC Standards Review Subcommittee	No	Is the scope of this SAR to make operators aware of the alarms?Keep close to the practices of the recommendations of the Blackout report. Some type of caution should be expressed in that entities should not be told how to operate or address their alarms. A guideline would be more appropriate for this proposed standards action. The operating environment should focus on reliable system operation and focus for the system operation staff. For example the size of the entity's system or how the entity is structured will vary the type of the tools used and would make it difficult to make a one-size fits all standard. There is concern that the SAR may be expecting research and development of tools. This is not an appropriate use of a SAR.
Response: The SAR DT has changed the title and wording of the SAR to make the intent clearer. This revised wording should alleviate your concerns. The SDT will have the flexibility to constrain solutions to specific entities based on defined criteria so that one size doesn't fit all. There was no intent to mandate research and		

Organization	Yes or No	Question 2 Comment
development of tools, indeed, the SAR does not mention tools at all but emphasizes functionality.		
IRC Standards Review Committee	No	The SAR scope while limiting itself to Alarming, Telemetry and Network Analysis does not excuse the fact that operational tools and their characteristics should NOT be mandated by NERC standards.Mandating tools and their characteristics will likely stifle innovation and will overlook or otherwise fail to consider the variations in the local characteristics that must be addressed by the affected entities; and can impact Market structures, integration of renewable resources, and adoption of smart grid devices.
ISO New England Inc.	No	The SAR scope while limiting itself to Alarming, Telemetry and Network Analysis does not excuse the fact that operational tools and their characteristics should NOT be mandated by NERC standards.Mandating tools and their characteristics will stifle innovation and will overlook the local characteristics that must be addressed by the affected entities; and can impact Market structures and integration of renewal resources and adoption of smart grid devices.
IESO	No	Mandating tools and their characteristics will stifle innovation and will overlook the local characteristics that must be addressed by the affected entities, and can impact market structures and integration and management of other emerging issues such as renewal resources and adoption of smart grid devices.
Response: The SAR does not mention tools or their characteristics but emphasizes functionality.		
American Transmission Company	No	Please see our comment to question 1.
CenterPoint Energy	No	See response to Q1.
Manitoba Hydro		See comment for Question 1.
Response: Please see response to comments in question 1.		
Xcel Energy	No	There is concern that the SAR may be expecting research and development of tools. This is not an appropriate use of a SAR.
Response: There was no intent to mandate research and development of tools, indeed, the SAR does not mention tools at all but emphasizes functionality.		
American Electric Power	No	AEP believes that these actions are largely covered in the existing standards, including those shown below (Table 1) in the related SAR functions format. Repetition of requirements across multiple standards may create ambiguity if alternative requirements or methods are defined from one to the other. It also establishes the possibility of compounding violations for a single infraction. To the extent that new requirements are needed to address operational gaps, these could be made in the next

Organization	Yes or No	Question 2 Comment
		revision of the applicable existing standards, which is to be done on a periodic basis. TABLE I - Existing NERC Reliability Standards addressing Alarming, Telemetry, Network Analysis, Related Performance Metrics (Availability and Quality), and Processes and Procedures supporting Real-Time Tools (Change Mgt., Maintenance Coordination, and Failure Notification) : Alarming COM-001-1.1, does have some language related to the alarming of vital telecommunications facilities for voice and data. TOP-006-2 stress the importance of monitoring equipment to be used to 'alarm' or bring to the attention of operating personnel important deviations in operating conditions and to indicate, if appropriate, the need for corrective action. IRO-002-2, gives direction on the alarming management and awareness systems that need to be in place for the RC. Telemetry BAL-001-0, dealing with the ACE equation along with Control Performance Standards (CPS1 and CPS2) BAL-004-0, addressing Time Error Corrections BAL-005-0.1b, focuses on the telemetry components necessary for calculating the ACE equation BAL-006-1.1, tasks the Balancing Authorities to calculate and record hourly Inadvertent Interchange IRO-004-1, details the information that needs to be sent to the RC for reliability studies to be performed IRO-005-3, breaks down most of the parameters that a RC would need to receive for monitoring the BES TOP-002-2, highlights that changes in transmission facility status, along with ratings should be monitored and conveyed to the RC and BA TOP-005-2 is the Operational Reliability Information standard that lays out all of the data that needs to be updated at least every ten minutes TOP-006-2 is another standard focused on monitoring system conditions. VAR-001-1 also is offering details on what data should be pipelined back to the operating control centers from the BES. Network Analysis IRO-004-1, discusses the ability for the RC, TO, and BA to conduct next-day reliability analyses to ensure that the BES can be operated reliably. TOP-002-2, looks at the performance of current-day, next-day, and studies operational studies in conjunction with neighboring BA(s) and TO(s).

Organization	Yes or No	Question 2 Comment
		TOP-002-2, also address the thermal and voltage contingency analysis that needs to be performed. IRO-002-2, details the analysis that needs to take place via state estimation and other visualization tools.Performance Metrics for Availability and Quality AvailabilityAvailability BAL-005-0.1b, R8 looks at SCADA availability to gather data and calculate ACE. This requirement also address the availability of Frequency Metering equipment (99.95%). COM-001-1.1, stresses the diversity and redundancy of communication paths for the available exchange of Interconnection and operating information, internally and externally to AEP. EOP-008-0, emphasizes the development of a plan to ensure the monitoring and control of transmission, distribution and generation assets even with the loss of the Control Center. Quality BAL-005-0.1b, R17 breaks down the accuracy of the metering devices for time error and frequency measurements BAL-006-1.1, requires adjacent balancing authorities to have common megawatt-hour meters at the interconnection point. IRO-005-3, discusses the importance of operating to the most limiting element if there is a discrepancy between various entities monitoring the same facilities. TOP-006-2 generically states that sufficient metering of suitable range, accuracy and sampling rate (if applicable) to ensure accurate and timely monitoring of operating conditions. Processes and Procedures supporting Real-Time Tools: Change Mgt., Maintenance Coordination, and Failure NotificationChange Management FAC-009-1, obligates the communication to RC(s), PA(s), TP(s), and TO(s) for new facility ratings on the Bulk Electric System. TOP-002-2, implies that there should be a facility change notification system in place for neighboring entities to use uniform line identifiers when referring to interconnected facilities. BAL-004-0, addressing Time Error Corrections Maintenance Coordination FAC-009-1, it is implied that these changes will be applied to the real time computer model with alterations to facility ratings on the Bulk Electric System. TOP-002-2, talks about each BA and TO maintaining accurate computer models for analyzing and planning system operations.Failure Notification IRO-005-3, highlights the responsibility to identify significant issues with ACE that can attribute to other errors, such as

Organization	Yes or No	Question 2 Comment
		frequency error and Time error.
Response: The SAR DT has revised the SAR to include the possibility of revising existing standards based on your research and comments. However, the SAR DT has only included TOP, IRO, and COM standards. The SAR DT does not believe it is necessary to include any other standards. The SAR DT researched the BAL, FAC, VAR, and EOP standards mentioned and has determined that they do not need to be included as they are not directly addressing the issues in the proposed scope of this SAR.		
City of Tallahassee	No	This should be targeted to the RC's initially. Let's get it up and running for them before we make it mandatory for the TO's and BA's. Many TO's and BA's will pursue them during the interim because they will know it is coming and can begin the long trek to get there.
Response: The SAR DT believes that Transmission Operators and Balancing Authorities are just as important to the reliability of the BES as are the Reliability Coordinators and thus should be included in this SAR from the outset.		
Duke Energy	No	We believe that the scope is too large to be manageable, and should be broken up into multiple projects.
Response: The SAR DT believes that the topics covered in the SAR are too closely related to be split up into different projects.		
RRI Energy	No	See comments from Question 1. This SAR should not include GOP in the applicability section.
Response: See response to question 1.		
NorthWestern Energy	No	NorthWestern Energy agrees that the scope of the SAR has merit for establishing guidelines, but not for developing a new standard. The functionality, performance, and management of Real-time tools for Reliability Coordinators, Transmission Operators, and Balancing Authorities need guidance and direction. However, the proposal for a new standard should be prolonged until reliability entities can implement real time practices, put forth from guidelines, and truly test the feasibility, functionality, performance, and management of Real-time tools
Response: Guidelines are only pertinent when associated with a particular standard or requirements. Furthermore, there are 2 directives in FERC Order 693 relating to tool capability that need to be addressed. The existing projects that would have handled these issues (Project 2006-02 for IRO-002 and Project 2007-03 for TOP-006) have clearly indicated that they expect this SAR to address the issues raised by FERC. Therefore, this SAR needs to move forward or the existing projects need to take back the responsibility for addressing the directives. This SAR is the logical place and method for starting this process and will tie this together. The eventual SDT has the flexibility to ask that any standard or standard revision go through a field test prior to implementation. Any field testing would be appropriate after the requirements have been drafted and prior to implementation.		

Organization	Yes or No	Question 2 Comment
Kansas City Power & Light	No	
Utility Services LLC	No	
Response: The SAR DT is unable to respond since you didn't include any specific reasons for your disagreement. In the future, please provide specifics so that the SAR DT can adequately respond to your concerns.		
Hydro One	Yes	I agree if items such as wide area displays, identificaion of equipment outages (tagging, colours) which are crucial for visualization are being considered in other standards.
Response: The SAR does not tell you 'how' to use the functionality but 'what' an entity needs to do.		
SERC OC Standards Review Group	Yes	See comments to Question 8.
Entergy Services	Yes	Entergy supports the SERC OC comments.
Response: Please see response to comments in question 8.		
WECC Reliability Coordination	Yes	It appears that there may be a dollar and resource impact associated with the new and revised standards, so a phased approach may be required.
Response: The eventual SDT would interpret how any new or revised standard(s) would be implemented and utilize a phased approach if they believe it warranted.		
Pugets Sound Energy	Yes	The SAR indicates it address selected recommendations in the RTBPTF Report. It appears the focus from the report is on 1. Reliability Toolbox and not recommendations listed in 2. Enhanced Operator Situational Awareness or 3. Address Six Major Issues to enhance the effectiveness of real-time tools which we would agree with at this time.
Response: The SAR DT has been handed a scope of action that deals with specific recommendations but not all the recommendations in the RTBPTF Report.		
NERC RTOSDT	Yes	Again, the RTOSDT takes no position on the scope.
Southern Company	Yes	This SAR covers the concerns spelled out in the Real-time Tools Survey Analysis and Recommendations report.

Response: Thank you for your response.		

3. The SAR emphasizes functionality, performance, and management of tools as opposed to naming specific tools. The intent is to describe 'what' needs to be done as opposed to 'how' to do it. Do you agree with this approach? If not, please state specific reasons why not.

Summary Consideration: The majority of commenters agree with the approach of the SAR. Those who disagreed were generally okay with the concept but concerned about drifting into 'how'. The SAR DT has changed the title and wording of the SAR to make the intent even clearer to alleviate the concerns of those who disagreed.

Organization	Yes or No	Question 3 Comment
Northeast Power Coordinating Council	No	NPCC agrees that the SAR needs to emphasize the "what" that needs to be done to ensure the reliable and effective functionality, performance, and management of Real-time tools, not the "how" to do it. General categories of types of tools, such as state estimators, contingency analysis programs, etc. can be mentioned. How the results or outputs from those tools are generated, or the management of those tools outside the operating floor, are outside the scope of a standard. The results and of those tools and how they are used (and ease of use), are the most important issues.
Response: The SAR DT agrees that the SAR emphasizes the 'what' and not the 'how'. The SAR DT has revised the title and wording of the SAR to clarify the intent.		
IRC Standards Review Committee	No	The IRC does agree with the principle that NERC standards should define "What" not "How". However, by defining the characteristics of alarms, of telemetry and of Network Analysis, this SAR will be defining the HOW of an entity alarming, metering and analyzing its system. It seems obvious that analytic tools used to analyze a small co-op would be quite different from the analytic tools needed to analyze a large RTO. The tools needed to analyze a stable/fixed load area would be quite different from a system with highly varying loads. The proposed standards will either create large inefficiencies for the smaller entity, or the standards will create inadequate requirements for the larger entity.
ISO New England Inc.	No	The IRC does agree with the principle that NERC standards should define "What" not "How". However, by defining the characteristics of alarms, of telemetry and of Network Analysis, this SAR will be defining the HOW of an entity alarming, metering and analyzing its system. It seems obvious that analytic tools used to analyze a small co-op would be quite different from the analytic tools needed used to analyze a large RTO. The tools needed to analyze a stable/fixed load area would be quite different from a system with highly varying loads. The proposed standards will either create large inefficiencies for the smaller entity, or the standards will create inadequate requirements for the larger entity.

Organization	Yes or No	Question 3 Comment
IESO	No	We support the principle that NERC standards should define the "What" not the "How". However, by defining the characteristics of alarms, of telemetry and of Network Analysis, this SAR will be defining the HOW of an entity will alarm, meter and analyze its system. The "what", in our view, will be an entity's capability to monitor and analyze the power system and respond to alarmed situations. We do not think that a standard that stipulates the characteristics and performance level of tools is necessary.
Response: The SAR DT has changed the title and wording of the SAR to make the intent clearer. The SDT will have the flexibility to constrain solutions to specific entities based on defined criteria so that one size doesn't fit all.		
American Electric Power	No	While we do agree that "what," not "how," is the correct approach to describe the required real time tools, we believe it should be established in the certification process as described in item #1 above. While it is easy to say we will confine ourselves to "what," it's difficult to prevent establishing criteria that inadvertently leads to a particular "how." Should "how" occur, it limits opportunities for improvements and innovation, and could hamper better results. AEP agrees with this approach of describing "what" needs to be done, as opposed to "how" to do it, as this preferred approach encourages new technology development in achieving the intent of the standard.
Response: Certification is a one time process. New certification criteria do not apply to entities that have already been certified. There is no re-certification process nor are there any plans that the SAR DT is aware of to expand the certification process to include re-certification. Certification only proves that an entity had the functionality at a single point in time. There is no operational history associated with certification; therefore, certification criteria that deal with Real-time operations or data are only evaluated by the certification team to determine if the entity has adequate functionality to go operational. Certification relies on the Compliance Monitoring and Enforcement Program (CMEP) to prove compliance for this functionality on an on-going basis. However, CMEP can only evaluate compliance to requirements defined in the Reliability Standards. Therefore, the SAR is necessary to allow the creation of standard requirements to address the issues raised in the SAR so they will be evaluated by CMEP. Furthermore, there are 2 directives in FERC Order 693 relating to tool capability that need to be addressed. The existing projects that would have handled these issues (Project 2006-02 for IRO-002 and Project 2007-03 for TOP-006) have clearly indicated that they expect this SAR (Project 2009-02) to address the issues raised by FERC. It is difficult to perceive how any additions or changes to the certification process could come up with a solution that would satisfy and sustain a mandatory and enforceable status for those directives. Therefore, this SAR needs to move forward or the existing projects need to take back the responsibility for addressing the directives. The approach taken by the Standards Development Program is not to write new requirements that assess basic capabilities used to achieve performance measured through other requirements within the Reliability Standards. The SAR DT has researched the standards and concluded that other requirements do not presently exist to adequately cover the issues raised in the SAR. This SAR is the logical place and method for starting this process. The SAR DT has changed the wording of the SAR to make the intent clearer. This should alleviate any concerns as to drifting towards a 'how'.		
City of	No	While I can appreciate NERC trying to avoid mentioning specific brand names, there is no point in not saying you have to have a

Organization	Yes or No	Question 3 Comment
Tallahassee		Contingency Analysis Program if that is what you want us to have. The continued interpretation of what NERC wants becomes a guessing game and we don't find out that we guessed wrong until we are audited.
Response: The SAR DT believes that there are multiple ways to achieve the desired results and that emphasizing functionality is the best method to use in the SAR. This point of view seems to be supported by the comments received.		
NorthWestern Energy	No	NorthWestern Energy agrees with this approach but not for the proposal/request of a standard. Guidelines that describe what needs to be done for the functionality, performance, and management of Real-time tools should be established for Reliability Coordinators (RC) first. Once a test and evaluation period is complete, then a new standard should be proposed for Transmission Operators (TOP) and Balancing Authorities (BA) with proper guidelines for implementation. RCs have the highest authority and wide area view of Interconnections, so it seems logical that new guidelines in this area should begin at the RC level first.
Response: Guidelines are only pertinent when associated with a particular standard or requirements. Furthermore, there are 2 directives in FERC Order 693 relating to tool capability that need to be addressed. The existing projects that would have handled these issues (Project 2006-02 for IRO-002 and Project 2007-03 for TOP-006) have clearly indicated that they expect this SAR to address the issues raised by FERC. Therefore, this SAR needs to move forward or the existing projects need to take back the responsibility for addressing the directives. This SAR is the logical place and method for starting this process and will tie this together.		
FirstEnergy	Yes	We agree with this approach and we encourage the SAR and subsequent effort of the SDT to focus on the minimum requirements (tools) needed to provide an Adequate Level of Reliability (ALR). The standard(s) should be careful to avoid prescriptive language that mandates the use of what could be considered cutting edge technologies that would cause inefficient use of limited resources.
MRO NERC Standards Review Subcommittee	Yes	This approach is stated on page 29 of NERCs "Drafting Team Guidelines". The Drafting Team must follow the guideline of establishing the "what" criteria for each requirement.
Response: Thank you for your response.		
American Transmission Company	Yes	This approach should be incorporated into the certification/re-certification process.
Response: Certification is a one time process. New certification criteria do not apply to entities that have already been certified. There is no re-certification process nor are there any plans that the SAR DT is aware of to expand the certification process to include re-certification. Certification only proves that an entity had the functionality at a single point in time. There is no operational history associated with certification; therefore, certification criteria that deal with Real-time operations or		

Organization	Yes or No	Question 3 Comment
data are only evaluated by the certification team to determine if the entity has adequate functionality to go operational. Certification relies on the Compliance Monitoring and Enforcement Program (CMEP) to prove compliance for this functionality on an on-going basis. However, CMEP can only evaluate compliance to requirements defined in the Reliability Standards. Therefore, the SAR is necessary to allow the creation of standard requirements to address the issues raised in the SAR so they will be evaluated by CMEP. Furthermore, there are 2 directives in FERC Order 693 relating to tool capability that need to be addressed. The existing projects that would have handled these issues (Project 2006-02 for IRO-002 and Project 2007-03 for TOP-006) have clearly indicated that they expect this SAR (Project 2009-02) to address the issues raised by FERC. It is difficult to perceive how any additions or changes to the certification process could come up with a solution that would satisfy and sustain a mandatory and enforceable status for those directives. Therefore, this SAR needs to move forward or the existing projects need to take back the responsibility for addressing the directives. The approach taken by the Standards Development Program is not to write new requirements that assess basic capabilities used to achieve performance measured through other requirements within the Reliability Standards. The SAR DT has researched the standards and concluded that other requirements do not presently exist to adequately cover the issues raised in the SAR. This SAR is the logical place and method for starting this process.		
WECC Reliability Coordination	Yes	Although it appears that in the survey results that some items are specifically mandated.
Response: This is not the RTBPTF Report but a SAR and an eventual SDT will be bound by the words of the SAR. Nothing is mandated.		
Duke Energy	Yes	See our comment to question #1 above. We are concerned that if requirements are overly prescriptive, they are describing “how” instead of “what”.
Response: See response to question 1.		
Pugets Sound Energy	Yes	PSE suggests caution in defining "what" needs to be done if it leads to "how much" needs to be installed. An over abundance of telemetry data and alarms can create complexity when responding to an event and must be displayed effectively to be valuable.
Response: The SAR DT has changed the wording of the SAR to make the intent clearer. The SAR is focused on functionality.		
RRI Energy	Yes	Provided that the lack of the how will not cause an issue during an audit.
Response: An auditor can only enforce what is cited in the standard requirements. If the requirements are ‘what’, then the auditor can only enforce ‘what’.		
SERC OC Standards Review	Yes	See comments to Questions 5 & 8.

Organization	Yes or No	Question 3 Comment
Group		
Entergy Services	Yes	Entergy supports the SERC OC comments.
Response: Please see response to comments in questions 5 & 8.		
Public Service Enterprise Group Companies	Yes	The SAR should be limited to the “what” and not include the “how.” There are multiple equally effective ways of accomplishing the “how” and the decision as to which to use should be left to the impacted registered entities.
NERC RTOSDT	Yes	The RTOSDT agrees, however, it seems unlikely to be achievable in this case. Discussions surrounding analytical capabilities seemingly always devolve to specific tools.
Midwest ISO	Yes	The Midwest ISO agrees the SAR should focus on “what” and not “how”.
Utility Services LLC	Yes	When appropriate, standards should never prescribe how.
Exelon; ComEd, PECO and Exelon Generation	Yes	Agree that it is very important that a standard or certification process for validating Real Time Tools does not direct the applicable entities to use specific tools. Exelon endorses the "what", not the "how" approach as emphasized in the SAR.
Ameren	Yes	This is the correct approach. Tools will change over time. Defining the “what” should be the focus. Leave the technical “how” to those developing solutions.
Hydro One	Yes	It is the end result that counts - how you get there will within reason be driven by the standards.
Manitoba Hydro	Yes	Although the SAR does not intend to indicate “how to” perform the specific tasks/requirements, it may be useful to identify tools in a separate document that could be used to achieve the specific task without directing the use of a specific one.
FMPA	Yes	It is very important that we focus on the "what" and not the "how". Smaller systems can easily meet the functionality requirements of an eventual standards without the need for expensive additional software.
Kansas City Power & Light	Yes

Edward Stein (self)	Yes	
Southern Company	Yes	
Response: Thank you for your response.		

4. The SAR focuses on alarming, telemetry, and network analysis. Do you agree that this is the right set of functions? If not, please state specific reasons why not.

Summary Consideration: The majority of respondents agree with the functions listed in the SAR. However, some concerns were raised that caused the SAR DT to change the title and wording of the SAR to make the intent clearer. Addition of other functions was suggested by some entities but there was no consensus on changing the scope in this regard.

Organization	Yes or No	Question 4 Comment
Northeast Power Coordinating Council	No	NPCC agrees that the functions stated are correct, but not all inclusive. The SAR needs to clarify that all of the functions contained in the Real Time Tools Report are not being addressed at this time due to the expansiveness of the RTBPTF report. There should be a fourth required functionality identified as Control. Control would include the application of and methods to ensure control capability is maintained at a control center and remote substations.
Response: The SAR explicitly states "This SAR addresses selected recommendations in the RTBPTF Report as determined by the Real-time Best Practices Standards Study Group: Project 2009-02." The study group organized to review the RTBPTF Report was restricted to those issues identified in the report.		
Public Service Enterprise Group Companies	No	If the scope of this SAR is expanded to include potential revisions to COM-001 and COM-002 to ensure that all three standards are non-duplicative, complementary and consistent, then PSEG concurs that alarming, telemetry and network analysis are the right set of functions.
Response: The SAR DT has expanded the scope of the SAR to include potential revisions to COM-001 but does not agree that COM-002 is pertinent to this SAR.		
MRO NERC Standards Review Subcommittee	No	Each RC, TOP, and BA will have a different set of needs based on System Operator experience. This is why alarming, telemetry and network analysis should be training requirements, not a new standard. When a RC, TOP, and BA follow the systematic approach to training, these items should be part of the company's reliability - related task list.It is also not clear as to how far reaching standards for these functions would be. For example, MRO NSRS would not be in support of anything that would infer the need to install duplicate instruments to provide information to a Reliability Coordinator (as in most cases this data is acquired by the TOP and BA and then passed to the RC).
Response: An entity could have a training program but you could be missing essential functions. The SAR does not mention duplicate instruments. The SAR only speaks to 'what'; 'how' things are done would be left to the individual entity.		
WECC Reliability	No	The survey results focus on additional items not listed above and do include data requirements such as day ahead study data

Organization	Yes or No	Question 4 Comment
Coordination		requirments, path limts requirement and special protection schemes monitoring applicability.
Response: The SAR is not dealing with all 40 recommendations of the report, just the items that are explicitly called out in the SAR.		
FMPA	No	The proposed functions do not seem to address the "visualization" over a wide geographic area aspect of blackout recommendations. "Visualization" probably ought to be added as a function applicable to Reliability Coordinators.
Response: The SAR DT believes that visualization is derived from the functionality that is spelled out in the SAR. Therefore, it is not needed as a separate item in the SAR.		
Xcel Energy	No	It is not clear as to how far reaching standards for these functions would be. For example, we would not be in support of anything that would infer the need to install duplicate instruments to provide information to a Reliability Coordinator (as in most cases this data is acquired by the TOP and BA and then passed to the RC).
Response: The SAR does not mention duplicate instruments. The SAR only speaks to 'what'; 'how' things are done would be left to the individual entity.		
American Electric Power	No	As described in item #2 above, we believe that these areas of focus are already covered in the existing standards (Table I). NERC is actively involved in consolidating standards in the revision process as witnessed in Project 2006-03. Creating new standards unnecessarily would be counter productive to this trend.
Response: Please see the response for question 2.		
City of Tallahassee	No	See response to question 1. Network Analysis does not need to be a requirement for smaller TO's. Until we can provide some way of avoiding the large expense without a measurable increase in reliability, we should not be pushing this function onto the TO. The TO's SHOULD be responsible for providing the data needed to the RC so his model works properly.
Response: The SDT will have the flexibility to constrain solutions to specific entities based on defined criteria so that one size doesn't fit all.		
Ameren	No	The SAR should include all aspects of the "Reliability Toolbox" as defined in the RTBPTF report.
Response: The SAR is not dealing with all recommendations of the report, just the items that are explicitly called out in the SAR.		
RRI Energy	No	The SAR's focus on "alarming, telemetry and network analysis" I believe supports dropping GOP from the applicability. Our EMS contains the alarms and telemetry needed to comply with standards and market rules. What level of network analysis does the SAR contemplate a GOP performing? Further, if a GOP feels that it needs to have unit AVR mode telemetry to insure compliance to VAR-002 then the GOP will add that alarm to its EMS. An additional standard requirement is not needed for the GOP to have

Organization	Yes or No	Question 4 Comment
		the necessary real time tools to support ALR of the BES.
Response: The SAR DT understands that not all elements of the SAR would apply to a Generator Operator. By checking the box for Generator Operator, the SAR DT is providing the eventual SDT with the flexibility to include a Generator Operator as an applicable entity if necessary. If the Generator Operator isn't checked off as an applicable entity in the SAR, the SDT does not have the flexibility to add them back in later if they are needed. However, if the Generator Operator is cited in the SAR and the SDT doesn't feel that they are needed in a standard, they can leave them off the list of applicable entities. For these reasons, the SAR DT feels that Generator Operators should continue to be listed as potential applicable entities in the SAR.		
NorthWestern Energy	No	NorthWestern Energy agrees with the focus on alarming and telemetry for all three of the reliability entities mentioned (Reliability Coordinators, Transmission Operators, and Balancing Authorities). The focus on network analysis should only apply to RCs first and then to TOPs and BAs. Northwestern Energy would also recommend having alarming for telemetry data only. Northwestern energy would not recommend replacing real-time alarming values with state estimated values. Again here NorthWestern Energy believes that the focus on alarming, telemetry, and network analysis should begin with guidelines and criteria before a standard is proposed/requested.
Response: The SAR DT believes that Transmission Operators and Balancing Authorities are just as important to the reliability of the BES as are the Reliability Coordinators and thus should be included in this SAR from the outset. How one utilizes data for alarming would be up to the individual entity and is not specified in the SAR as the SAR emphasizes functionality and 'what' as opposed to 'how'. The SDT has the flexibility to ask that any standard or standard revision go through a field test prior to implementation. That is not a consideration for a SAR.		
Kansas City Power & Light	No	Operational situational awareness is a very complex mix of tools and displays of graphical and tabular information. It will be an extraordinarily difficult effort for a standard to capture that mix. The current standards and requirements that require sufficient monitoring, outage coordination, outage evaluation, mitigation plans for extreme operating conditions, etc. taken all together form a comprehensive assemblage of reliability principles that are sufficient to address the concerns of the August 14 black-out report.
Response: The SAR DT does not agree that the existing standards cover the issues of performance metrics or availability.		
Utility Services LLC	No	
IESO	No	We do not agree with the need for such a standard.
Response: Thank you for your response.		
IRC Standards Review	No	See responses above.

Organization	Yes or No	Question 4 Comment
Committee		
ISO New England Inc.	No	See responses above.
CenterPoint Energy	No	See response to Q1.
American Transmission Company	Yes	Please see our comment to question 1.
Response: Please see response to comments in question 1.		
Oncor Electric Delivery	Yes	Smaller entities operating within the bulk electric system may bear a higher burden than larger ones. The benefits of providing real-time network analysis for these smaller entities may be far less than the costs.
Response: The SDT will have the flexibility to constrain solutions to specific entities based on defined criteria so that one size doesn't fit all.		
Exelon; ComEd, PECO and Exelon Generation	Yes	Exelon suggests historical data (storage and retrieval) should also be considered as an appropriate function. Also, while these may be the right functions for Real Time Tools, a total systems approach should be emphasized as opposed to focusing on "silos" of information and functions, RTU data, hardware, software etc.
Response: This project, if authorized by the Standards Committee, will be restricted to the items identified in the SAR.		
Hydro One	Yes	Network analysis is so broad that many functions can be included in this category i.e. dynamic equipment ratings, short circuit analysis, breaker duty cyclee etc that this SAR can be as broad as required.
Response: The SAR has been clarified to more clearly indicate the intent of the SAR DT.		
NERC RTOSDT	Yes	The RTOSDT takes no position on this issue.
Electric Market Policy	Yes

Response: Thank you for your response.		

5. The SAR details the need for performance metrics for availability, quality, change management, maintenance coordination, and failure notification. Do you agree that this is the correct set of metrics? If not, please state specific reasons why not.

Summary Consideration: The SAR DT has changed the title and wording of the SAR to provide greater clarity. The SAR has been revised to specify that any metrics will be vetted by the industry through the standards comment process.

Organization	Yes or No	Question 5 Comment
Northeast Power Coordinating Council	No	The statement in Question 5 should be worded "The SAR details the need for performance metrics for alarming, telemetry, and network analysis functionalities, with the considerations of availability, quality, change management, maintenance coordination, and failure notification." What is meant by the term "change management"?
Response: In the context of this SAR, change management is the process in which changes are implemented in a controlled manner by following pre-defined procedures.		
SERC OC Standards Review Group	No	The SERC OC Standards Review Group supports placing any requirements related to this SAR in the Certification process. As such, this conversation is premature at this time, and should be held with the industry when the final location of these requirements is decided. It is unclear at this time how performance metrics would be tracked or enforced if the requirements become certification requirements.
Entergy Services	No	Entergy supports the SERC OC comments.
Response: Certification is a one time process. New certification criteria do not apply to entities that have already been certified. There is no re-certification process nor are there any plans that the SAR DT is aware of to expand the certification process to include re-certification. Certification only proves that an entity had the functionality at a single point in time. There is no operational history associated with certification; therefore, certification criteria that deal with Real-time operations or data are only evaluated by the certification team to determine if the entity has adequate functionality to go operational. Certification relies on the Compliance Monitoring and Enforcement Program (CMEP) to prove compliance for this functionality on an on-going basis. However, CMEP can only evaluate compliance to requirements defined in the Reliability Standards. Therefore, the SAR is necessary to allow the creation of standard requirements to address the issues raised in the SAR so they will be evaluated by CMEP. Furthermore, there are 2 directives in FERC Order 693 relating to tool capability that need to be addressed. The existing projects that would have handled these issues (Project 2006-02 for IRO-002 and Project 2007-03 for TOP-006) have clearly indicated that they expect this SAR (Project 2009-02) to address the issues raised by FERC. It is difficult to perceive how any additions or changes to the certification process could come up with a solution that would satisfy and sustain a mandatory and		

Organization	Yes or No	Question 5 Comment
enforceable status for those directives. Therefore, this SAR needs to move forward or the existing projects need to take back the responsibility for addressing the directives. The approach taken by the Standards Development Program is not to write new requirements that assess basic capabilities used to achieve performance measured through other requirements within the Reliability Standards. The SAR DT has researched the standards and concluded that other requirements do not presently exist to adequately cover the issues raised in the SAR. This SAR is the logical place and method for starting this process.		
MRO NERC Standards Review Subcommittee	No	Are the above metrics for the functions of Alarming, Telemetry, and Network analysis? A metrics is simple standard of measure. MRO NSRS understands that a metrics can be used in a measurement of a quantitative action, but how it would be used during “current operations” is not apparent. Perhaps this SAR should be more System Operator training based. If metrics were to be developed, any requirements created to impose metrics should allow for exceptions for extended outages of equipment for uncontrollable reasons. As written in the recommendation report, an outage on a real time tool for as short as a few hours could create significant non-compliance events, while not having any impact to the reliability of the system.
Response: Yes, these metrics are for the identified functions. An entity could have a training program but you could be missing essential functions. The wording of the SAR has been revised to show that any performance metrics would have to be vetted by the industry as part of the standards comment process.		
IRC Standards Review Committee	No	Metrics of tool performance may sound like a great idea, however such standards will unintentionally create a environment where tool characteristics become a goal unto itself, as opposed to an environment where ensuring transmission system reliability is the goal.NERC standards should be written to drive proper behavior and stipulate specific performance level of an entity to perform the tasks associated with the function for which it is registered. Those standards do not excuse that entity because the primary tool the entity uses is not available. Today’s standards impose an implied obligation to have redundant / back-up tools to ensure that system reliability is maintained, regardless of tool’s capability and availability in use. Tool metrics will create needless penalties, and are not drivers for proper behavior to ensure reliability. If a tool does not perform as this proposed SAR mandates, then the entity will be assessed non-compliant EVEN THOUGH the entity is meeting the primary goal of maintaining reliability. Tool unavailability is not the same as transmission performance problems. Bad or malfunctioning tools, in themselves, do not equate to a bad behavior or system performance. The IRC would also note that there are currently requirements to ensure that tools are maintained and properly managed (see CIP-007 and IRO-002 R9). This suffices to ensure that the responsible entity has the needed tool capability to perform its tasks.
ISO New England	No	Metrics of tool performance may sound like a great idea, however such standards will create a environment where tool

Organization	Yes or No	Question 5 Comment
Inc.		characteristics become a goal unto itself, as opposed to an environment where ensuring transmission system reliability is the goal.NERC standards should be written to drive proper behavior and stipulate specific performance level of an entity to perform the tasks associated with the function it registers as. Those standards do not excuse that entity because the primary tool the entity uses is not available. Today's standards impose an implied obligation to have redundant / back-up tools to ensure that system reliability is maintained, regardless of tool's capability and availability in use. Tool metrics will create needless penalties, and are not drivers for proper behavior to ensure reliability. If a tool does not perform as this proposed SAR mandates, then the entity will be assessed non-compliant EVEN THOUGH the entity is meeting the primary goal of maintaining reliability. Tool unavailability is not the same as transmission performance problems. Bad tools do not equate to a bad behavior or system performance. The SRC would also note that there are currently requirements to ensure that tools are maintained and properly managed (see CIP-007 and IRO-002 R9). This suffices to ensure that the responsible entity has the needed tool capability to perform its tasks.
IESO	No	NERC standards should be written to drive proper behavior and stipulate specific performance level of an entity to perform the tasks associated with the function it registers as. Such standards should not excuse that entity for non-compliant because the primary tool the entity uses is not available. Today's standards impose an implied obligation to have redundant / back-up tools to ensure that system reliability is maintained, regardless of tool's capability and availability. Tool metrics will create unnecessary requirements and penalties, and are not drivers for proper behavior to ensure reliability. If a tool does not perform the requirements that this proposed SAR mandates, then the entity will be assessed non-compliant even though the entity may be meeting the primary goal of maintaining reliability. We would also note that there are currently requirements to ensure that tools are maintained and properly managed (see CIP-007 and IRO-002 R9). This suffices to ensure that the responsible entity has the needed tool capability to perform its tasks.
Response: The loss of functionality could result in lack of adequate situational awareness. Metrics are needed to measure the performance and availability of those functionalities required to maintain BES reliability. CIP standards refer to critical assets at a system level while this SAR is meant to apply to the functionality described within the SAR. IRO-002 only applies to the Reliability Coordinator and tools while this SAR is meant to apply to additional entities and functionality.		
Southern Company	No	Availability and quality would be acceptable measureable metrics.Change management, maintenance coordination, and failure notification are processes and would have to be measured through documentation.
Response: The SAR has been changed to address this comment.		
FMPA	No	The proposed metrics are primarily very IT system focused metrics that may not be directly correlated with the reliability of the Bulk Electric System. The metrics ought to be focused more on what is important to reliable operations, such as accuracy of information, timeliness of information, etc. If you think of it, in order to have accurate and timely information, an IT systems will need to be

Organization	Yes or No	Question 5 Comment
		available, maintenance will have to have been coordinated, etc. The metrics proposed lean towards "how" and not "what".
Hydro One	No	One thing not indicated under performance metrics is actual performance i.e. alarm bursts, state estimator solve time or frequency of run, contingency analysis completeion time. If a SE only runs every 30min and takes 10min to solve how effective is it?
Response: The SAR does not mention specific metrics. The SAR has been revised to specify that any metrics will be vetted by the industry through the standards comment process.		
American Transmission Company	No	If this SAR is continued then the team needs to provide more information about the proposed performance metrics. (i.e. Definition(s), Calculation(s), Exclusion(s) and Goal(s)) In addition, the team should gather and provide information that can support the establishment of a minimum performance level. Setting a performance level will require strong technical support.
Oncor Electric Delivery	No	“Quality” should not be included. “Quality” is fundamentally subjective and cannot be measured
Exelon; ComEd, PECO and Exelon Generation	No	Exelon agrees performance metrics are important but we seek clarification concerning how quality, maintenance coordination, failure notification and especially change management are to be measured.
NERC RTOSDT	Yes	The RTOSDT agrees that a set of metrics is useful. Further, the RTOSDT believes that NERC must grapple with the concept that no information system is perfect. That is, requirements that involve information systems should only specify a "designed" level of performance, not the actual level of performance. It is nonproductive to investigate and fine an entity for failing to have two scans of an RTU, for example. The intent of a requirement related to information systems should always allow for reasonable failover times if redundancy is required and should allow for something less than 6 sigma performance, especially considering that communication networks outside of the control of reliability entities may have at best 2 sigma performance.
Alberta Electric System Operator	Yes	Yes, as long as metrics for “availability” is sufficiently defined and would also include "response".
South Carolina Electric and Gas	Yes	While we agree that the performance metrics should be part of the Standard, these metrics must allow for some level of equipment failure, communication failure, etc. and should not be a 100% performance requirement.
Response: The SAR has been revised to specify that any metrics will be vetted by the industry through the standards comment process.		

Organization	Yes or No	Question 5 Comment
CenterPoint Energy	No	See response to Q1.
Kansas City Power & Light	No	See response to question #1.
Response: Please see response to question 1 comments.		
American Electric Power	No	AEP believes that these actions are largely covered in the existing standards, including those shown previously (Table 1) in the related SAR functions format. Repetition of requirements across multiple standards may create ambiguity if alternative requirements or methods are defined from one to the other. It also establishes the possibility of compounding violations for a single infraction. To the extent that new requirements are needed to address operational gaps, these could be made in the next revision of the applicable existing standards.In any case, if this SAR proceeds, it must be limited to the “what” issues of “availability” and “quality”, and NOT on the “How” issues of "change management", "maintenance coordination", and "failure notification."
Response: Please see responses to previous AEP comments.		
Xcel Energy	No	Any requirements created to impose metrics should allow for exceptions for extended outages of equipment for uncontrollable reasons. As written in the recommendation report, an outage on a real time tool for as short as a few hours could create significant non-compliance events, while not having any impact to the reliability of the system.
Response: The SAR has been revised to specify that any metrics will be vetted by the industry through the standards comment process. The SAR is not the recommendation report – an eventual SDT would be bound by the language of the SAR. The loss of functionality could result in lack of adequate situational awareness.		
City of Tallahassee	No	The SAR identifies 2 performance metrics, Availability and Quality. The remaining three functions are not metrics; they will be requirements to ensure the entities have them. The use of metrics for enforcement will become contentious. If I say I am sending data to the RC over my data link, but he says he is not getting it, who gets charged with the non-availability or reduced quality? If the problem is with a third party communication (Sprint, AT&T, etc) why should I get penalized for the “network” failure? There are too many things beyond the control of the entity to make it a “mandatory and enforceable” metric.
Response: The SAR has been changed to address this comment. An entity should be able to prove whether they sent the data and that will determine who is responsible.		

Organization	Yes or No	Question 5 Comment
Contracts with the 3rd party vendors should handle issues such as network failures. Someone has to bear the accountability for failures. The SAR has been revised to specify that any metrics will be vetted by the industry through the standards comment process.		
Duke Energy	No	These are good metrics, but they don't belong in a reliability standard. Performance metrics should be implemented and enforced as part of the certification process.
Response: Certification is a one time process. New certification criteria do not apply to entities that have already been certified. There is no re-certification process nor are there any plans that the SAR DT is aware of to expand the certification process to include re-certification. Certification only proves that an entity had the functionality at a single point in time. There is no operational history associated with certification; therefore, certification criteria that deal with Real-time operations or data are only evaluated by the certification team to determine if the entity has adequate functionality to go operational. Certification relies on the Compliance Monitoring and Enforcement Program (CMEP) to prove compliance for this functionality on an on-going basis. However, CMEP can only evaluate compliance to requirements defined in the Reliability Standards. Therefore, the SAR is necessary to allow the creation of standard requirements to address the issues raised in the SAR so they will be evaluated by CMEP. Furthermore, there are 2 directives in FERC Order 693 relating to tool capability that need to be addressed. The existing projects that would have handled these issues (Project 2006-02 for IRO-002 and Project 2007-03 for TOP-006) have clearly indicated that they expect this SAR (Project 2009-02) to address the issues raised by FERC. It is difficult to perceive how any additions or changes to the certification process could come up with a solution that would satisfy and sustain a mandatory and enforceable status for those directives. Therefore, this SAR needs to move forward or the existing projects need to take back the responsibility for addressing the directives. This SAR is the logical place and method for starting this process.		
NorthWestern Energy	No	Northwestern Energy agrees with the performance metrics; however the whole set will be applicable only for alarming and telemetry purposes. Furthermore, the metrics need to be tested and evaluated before a standard can be requested.
Response: The intent of the SAR is that performance metrics are applicable to all functionality specified in the SAR. The SAR has been revised to specify that any metrics will be vetted by the industry through the standards comment process. The eventual SDT has the flexibility to ask that any standard or standard revision go through a field test prior to implementation. Any field testing would be appropriate after the requirements have been drafted and prior to implementation.		
Pugets Sound Energy	No	Availability and quality appear to be performance metrics. Change management, maintenance coordination, and failure notification do not seem to be performance metrics as stated. These may also overlap significantly with the CIP standards and should be aligned effectively.

Organization	Yes or No	Question 5 Comment
Response: The SAR has been changed to address this comment. CIP standards refer to critical assets at a system level while this SAR is meant to apply to the functionality described within the SAR.		
Utility Services LLC	No	
Response: The SAR DT is unable to respond since you didn't include any specific reasons for your disagreement. In the future, please provide specifics so that the SAR DT can adequately respond to your concerns.		
WECC Reliability Coordination	Yes	The word quality needs to be clearly defined and measurable.
Response: The SAR wording has been revised and 'quality' is no longer used.		
Manitoba Hydro	Yes	Manitoba Hydro agrees that this is the correct set of metrics; however the definition and measures defined in the Standard will have to be very specific and defendable in terms of improving reliability.
Response: The SAR DT agrees.		
Midwest ISO	Yes	We largely agree with the need for the performance metrics; however, we caution the drafting team to avoid duplicating already existing similar requirements. IRO-002 R9 already requires the RC to have approval for tool outages. CIP-007 already requires a change management process.
Response: CIP standards refer to critical assets at a system level while this SAR is meant to apply to the functionality described within the SAR. IRO-002 only applies to the Reliability Coordinator and tools while this SAR is meant to apply to additional entities and functionality.		
Ameren	Yes

Response: Thank you for your response.		

6. The SAR proposes to re-define Real-time. Do you agree that a new definition is needed? If not, please state specific reasons why not. If possible, specific suggested wording for a new definition would be appreciated.

Summary Consideration: Due to the industry comments received, the SAR DT has decided to delete the re-definition of Real-time from the SAR.

Organization	Yes or No	Question 6 Comment
Public Service Enterprise Group Companies	No	If “real-time” is redefined in the NERC glossary, it will be necessary to analyze the impact of this definitional change in each of the over 100 usages of this term throughout the full body of standards. If there is a particular concern about the speed/accuracy of “real-time” for this standard, then the specific requirement should be specified in this standard and not as a general definitional change.
SERC OC Standards Review Group	No	NERC should proceed only with extreme caution when “redefining” a commonly understood industry term. If there is a need to define a new concept that is somewhat close to the meaning of Real-time, NERC should label that concept something other than Real-time. Because the term “Real-time” is commonly understood in the industry, the definition for Real-time in the NERC Glossary could be deleted. As auditing staff attempts to assess compliance with requirements during a future audit, it should not have to determine the vintage of a definition that helps explain the intent of a requirement.
Entergy Services	No	Entergy supports the SERC OC comments.
IRC Standards Review Committee	No	This proposal will more likely cause unintended consequences. The SAR requestor states that the redefinition is needed because of inherent time-delays in data. The outcome of a strict definition could be that all data must be sampled at the same universal time. The result of such a noble idea would be to impose unjustified costs on every entity in North America. These costs will result because not every point can be obtained at the exact same time unless the requesting entity has a huge capability to gather data simultaneously. A likely result of such standards will be unbundling responsibility into smaller entities. That in turn will result in less than wide-area analysis. That in turn will result in a less reliable bulk power system.
ISO New England Inc.	No	This proposal will more likely cause unintended consequences. The SAR requestor states that the redefinition is needed because of inherent time-delays in data. The outcome of a strict definition could be that all data must be sampled at the same universal time. The result of such a noble idea would be to impose unjustified costs on every entity in North America. These costs will result because not every point can be obtained at the exact same time unless the requesting entity has a huge capability to gather data simultaneously. A likely result of such standards will be unbundling responsibility into smaller entities. That in turn will

Organization	Yes or No	Question 6 Comment
		result in less than wide-area analysis. That in turn will result in a less reliable bulk power system.
Southern Company	No	If a NERC Glossary term used in other standards is re-defined than the meaning of those standards has been changed without revision. The IRO standards use real-time as a description of a planning horizon or describing the data being used. Personnel operating the bulk power system understand that real-time data can be several seconds to several minutes old. The team may want to define the limits of near real-time data.
Hydro One	No	It is a good discussion point but it is splitting hairs a bit. Real Time is what you see now whether it took 5 minutes to get all the information or SE to solve. If the concept is to define how long it takes to refresh the data i.e. a 2 second refresh then that will drive home performance.
Con Edison System Operation	No	Changing the definition would be confusing. Adding a new term or making people become familair with using the "real time" term and another term such as "future time" would seem to be logical also.
IESO	No	This proposal will more likely cause unintended consequences. The SAR suggests that a redefinition is needed because of inherent time-delays in data. The outcome of a strict definition could be that all data must be sampled at the same universal time. The result of such a noble idea would be to impose unjustified costs on every entity in North America. These costs will result because not every point can be obtained at the exact same time unless the requesting entity has a huge capability to gather data simultaneously. A likely result of such standards will be smaller entities. That in turn will result in less than wide-area analysis. That in turn will result in a less reliable bulk power system. Real time operation is generally understood to be now and the next several minutes up to an hour. Any attempt to redefine the term Real Time to suit the purpose of tool characteristics or requirements will introduce problems or serious implications to the requirements governing real time operations.
Edward Stein (self)	No	Wordsmithing the definition of real time is a huge waste of (real) time. Everyone knows that real time data is between two and five seconds old (maybe even longer) depending on the scan rate. There has been some type of sabotage reporting rule or requirement for over 30 years because it was the sexy and politically correct thing to do even though there was no way that a System Operator, with his office in the middle of a corn field, knew if the line trip was due to sabotage or not. Even when the troubleman arrived at the scene of the outage, he still may not be able to determine if the tower fell down because it was a sabotage event or a local farmer removing some of the tower's bracing in order to use the bracing to hold up his corn crib.
MRO NERC Standards Review Subcommittee	No	The current definition as listed in the NERC glossary is adequate. Real-Time is an understood concept within the industry.
American Electric Power	No	Real-time is a precisely NERC defined term. In addition the Real-time term is highly integrated in the existing standards. Re-defining the term could have a significant impact on a wide-range of existing standards.

Organization	Yes or No	Question 6 Comment
Midwest ISO	No	There does not appear to be any compelling reason to change the definition. It is likely any changes will only cause confusion.
RRI Energy	No	I was unable from the SAR to understand why their was a need to redefine Real-time.
CenterPoint Energy	No	The current definition is sufficient. Any inherent time delay involved in the acquisition and dissemination of data to system operation personnel is understood. While that delay should be minimized, there are technical and financial limits to what can be done.
ReliabilityFirst Corporation	No	I do not think a new defintion is needed.
Exelon; ComEd, PECO and Exelon Generation	No	Exelon does not endorse a re-definition of Real-time.
Xcel Energy	No	
Utility Services LLC	No	
Alberta Electric System Operator	No	
American Transmission Company		A new definition will likely be needed if this project moves into a standards development phase; otherwise the existing definition may be suitable. (The certification / re-certification may not need to define Real-time but only identify minimum tools required for certification.)
Response: The SAR has been revised and the re-definition of Real-time has been deleted due to industry comments on this topic.		
Northeast Power Coordinating Council	Yes	NPCC agrees that the current definition that exists in the NERC Glossary of Terms where Real-Time is defined as “Present time as opposed to future time” is inadequate and needs to be redefined. Suggested rewording is: Real-time: 1. Existing or presently occurring. 2. In an information gathering or analysis environment, real time data and a time window allowed for its processing.
Response: Other commenters pointed out the far reaching effects of changing this definition. The SAR DT has discussed this matter and decided that a new		

Organization	Yes or No	Question 6 Comment
definition is not required for this SAR. The re-definition of Real-time has been deleted from the SAR.		
FirstEnergy	Yes	We agree with the SAR's recommendation to revisit the definition of Real-time. However, if revised, the SDT should carefully consider any unintended impacts a change in definition may have on other existing reliability standards that reference the existing term.
FMPA	Yes	The definition would go hand in hand with a key metric for the standard that probably ought to be added, timeliness of information. E.g., if a Transmission Owner is using a 10 minute rating for a line and it takes 5 minutes for the operator to even receive information that the line is beyond its normal rating, then the operator really only has about 5 minutes to make a decision and take action to reduce the loading on the line. Obviously, the more time the operator has to make decisions and take action in a deliberate fashion, the more reliable the power system. One key way to do this is to define "real-time" with a reasonable time delay maybe 3 minutes.
Manitoba Hydro	Yes	Present or current time seem to mean the same. Suggested definition: The actual time at which an event occurs.
South Carolina Electric and Gas	Yes	However, it should be noted in the Standard that there is an inherent delay in data acquistion, data processing, and data analysis. As such, things are not measured or calculated in real time per se, but are done as close to real time as practically possible. It should also be noted that caution should be used if this term is re-defined as this is a commonly used and understood industry term.
Pugets Sound Energy	Yes	Suggest aligning with the Real Time Operations Time Horizon for which each requirement is assessed relative to a violation. This would ensure no confusion.
NERC RTOSDT	Yes	The RTOSDT takes no position on this at this time. However, unintended consequences may occur. This needs a lot more explanation to the industry.
Ameren	Yes	Clarification of this term could be beneficial. “Real Time” can indicate significantly different time periods depending on the point of view. With the advent of new technologies such as phasor measurement units with a much higher sample rate, real time takes a very different meaning as compared to the traditional “seconds” based sample rates utilized in most current EMS/SCADA systems.
NorthWestern Energy	Yes	Northwestern Energy believes that a new definition which explains more about what is expected out of “Real Time” is needed. The current definition is vague and broad, a more defined timeframe would provide better operating criteria and guidelines to Reliability Coordinators, Transmission Operators and Balancing Authorities

Organization	Yes or No	Question 6 Comment
NERC RTOSDT	Yes	The RTOSDT takes no position on this at this time. However, unintended consequences may occur. This needs a lot more explanation to the industry.
Oncor Electric Delivery	Yes	There will be an inherent delay in the processing of applications, processing of data and the identification of contingency measures related to real time analysis for as much as 15 minutes. On the other hand, typical telemetry updates of data to the user display are around 2-4 seconds.
Consumers Energy Company	Yes	The existing definition is not useful.
Kansas City Power & Light	Yes	
Duke Energy	Yes	
City of Tallahassee	Yes	
PacifiCorp	Yes	
Bonneville Power Administration	Yes	
WECC Reliability Coordination	Yes	
Response: Other commenters pointed out the far reaching effects of changing this definition. The SAR DT has discussed this matter and decided that a new definition is not required for this SAR. The re-definition of Real-time has been deleted from the SAR.		

7. The SAR includes the Generator Operator (GOP) as a possible applicable entity. Do you agree that a potential Standards Drafting Team should have the freedom to consider the GOP as an applicable entity? If not, please state specific reasons why not.

Summary Consideration: The SAR DT understands that not all elements of the SAR would apply to a Generator Operator. By checking the box for Generator Operator, the SAR DT is providing the eventual SDT with the flexibility to include a Generator Operator as an applicable entity if necessary. If the Generator Operator isn't checked off as an applicable entity in the SAR, the SDT does not have the flexibility to add them back in later if they are needed. However, if the Generator Operator is cited in the SAR and the SDT doesn't feel that they are needed in a standard, they can leave them off the list of applicable entities. For these reasons, the SAR DT feels that Generator Operators should continue to be listed as potential applicable entities in the SAR.

If the eventual SDT decides to include the Generator Operator, they will constrain the applicability to only those items that directly apply. Codes and statutes will be adhered to in any eventual standard.

Organization	Yes or No	Question 7 Comment
Electric Market Policy	No	Most Transmission Operators (TOP) and Reliability Coordinators (RC) typically operate out of one control facility with information that expands beyond that provided by facilities under their direct control. There are protocols for coordinating operations of multiple facilities operated by different entities. Most Generator Operators (GOP) operate out a control room that contains information ONLY on facilities directly under that GOP's control. They are no protocols for coordinated operation of generating facilities. GOPs are to follow directives of the TOP and RC. Also, the federal/state codes/standards of conduct may prohibit dissemination of certain information between the RC/TOP and GOP entities. We strongly believe that placing new compliance requirements in this SAR on all generators is beyond the scope of what GOPs should be functionally doing in almost all generation locations on the bulk electric system and hence advancement of this standard with the inclusion in GOP applicability will actually create unnecessary complexity in operating the bulk electric system.
Ameren	No	It states that there would be a focus on Alarming to alert on events and conditions affecting the state of the BES, Telemetry to provide status and analog values in real time (status of what?), and Network Analysis for simulating impact of what-if events. For Alarming, what action would a GOP take in response to an alarm, that would be independent of what GOP would be directed to do by TO or BA or RC? GOP is already subject to plenty of other NERC Reliability Standards that state that the GOP has to do what the BA/TO/RC tell him/her to do in order to preserve the BES integrity. For Telemetry, regarding status (if assume of Transmission Components) inreal-time operation, doesn't that violate FERC Code of Conduct, since GOP is not supposed to know about Transmission information that may give him/her an advantage in the market? And as for Network Analysis, that has nothing to do with a GOP.

Organization	Yes or No	Question 7 Comment
Response: The SAR DT understands that not all elements of the SAR would apply to a Generator Operator. By checking the box for Generator Operator, the SAR DT is providing the eventual SDT with the flexibility to include a Generator Operator as an applicable entity if necessary. If the Generator Operator isn't checked off as an applicable entity in the SAR, the SDT does not have the flexibility to add them back in later if they are needed. However, if the Generator Operator is cited in the SAR and the SDT doesn't feel that they are needed in a standard, they can leave them off the list of applicable entities. For these reasons, the SAR DT feels that Generator Operators should continue to be listed as potential applicable entities in the SAR. If the eventual SDT decides to include the Generator Operator, they will constrain the applicability to only those items that directly apply. Codes and statutes will be adhered to in any eventual standard.		
Public Service Enterprise Group Companies	No	Generator Operators do not fit within the scope of this standard. They do not have direct involvement in the matters covered by this SAR. Any necessary GOP actions or requirements would be covered in the interconnection or operating agreements between generators and the applicable entities.
SERC OC Standards Review Group	No	If a need later develops to make the GOP applicable, then a SAR could be generated to cover the GOP at that time
Entergy Services	No	Entergy supports the SERC OC comments.
MRO NERC Standards Review Subcommittee	No	A GOP follows dispatch instructions from a BA or prior committed schedule and will be held accountable if those instructions are not followed. There is no need to have GOPs within this SAR.
FMPA	No	Why would a GOP have need for this? Most GOPs are radial to the interconnection point, so a contingency analysis will reveal nothing. The TOPs and RC will already be including the loss of generation or other contingencies in their contingency analysis. The only real involvement with the GOP is their metering and RTUs if the TOPs, BAs and RCs are depending on the GOPs information as data points in the control systems. There could be a requirement that the GOPs provide data to the TOPs / BAs / RCs through metering, RTUs and communication links to the TOPs / BAs / RCs criteria, but that should be the extent of what is required of GOPs, and, if that is a requirement of GOPs, then we would seriously need to consider LSEs and DPs as applicable entities to receive accurate load, losses and power factor information. This sort of requirement, however, probably belongs in the COM standards.
American Electric Power	No	AEP does not believe that it is necessary to include the GOP as an applicable function for this SAR, as data requirements are specified in existing standards. As mentioned in Item #1, using the NERC certification process of functional entities to ensure that the right tool set is in place and operating correctly is preferable to allowing, by administrative registration alone, to begin operating and then, afterwards, try to invoke standards to address operating issues that could have been avoided up-front.

Organization	Yes or No	Question 7 Comment
Oncor Electric Delivery	No	Generator Operators provide alarming and telemetry for their own facilities and only a small amount of this data is typically available to assist in determining the security of the bulk power system. In addition, Generator Operators do not normally perform network analysis.
Exelon; ComEd, PECO and Exelon Generation	No	Exelon sees no value in including the Generator Operator in the standard applicability. Data exchange and communication requirements are covered in other standards such as the COM and IRO standards. Additionally, RTO's, BA's and Transmission Owners and Operators typically specify in Interconnection Guidelines, Operating or Reliability Agreements and Manuals, what data must be shared between the Reliability Entities and the Generator Operators so as to support Real-time operational analysis.
RRI Energy	No	See previous comments.
Dynegy	No	The Generator Operator is not currently subject to this group of Standards. The Generator Operator should not be listed as a possible applicable entity without some technical justificatio from the SAR Drafting team.
South Carolina Electric and Gas	No	
Midwest ISO	No	There is no need to include the GOP. The GOP clearly has no need for network analysis capabilities.
Response: The SAR DT understands that not all elements of the SAR would apply to a Generator Operator. By checking the box for Generator Operator, the SAR DT is providing the eventual SDT with the flexibility to include a Generator Operator as an applicable entity if necessary. If the Generator Operator isn't checked off as an applicable entity in the SAR, the SDT does not have the flexibility to add them back in later if they are needed. However, if the Generator Operator is cited in the SAR and the SDT doesn't feel that they are needed in a standard, they can leave them off the list of applicable entities. For these reasons, the SAR DT feels that Generator Operators should continue to be listed as potential applicable entities in the SAR.		
IESO		This question is unclear because the GOP is an applicable entity for NERC standards. Does a GOP need to analyze the network performance? If that is the question, the answer is NO; a GOP needs only operate a generator, the TOP / RC must conduct network analyses.
IRC Standards Review Committee		This question is unclear because the GOP is an applicable entity for NERC standards. Does a GOP need to do Network Analysis? If that is the question, the answer is NO; a GOP must operate a Generator, the TOP / RC must do the transmission analysis.Equally inappropriate would be to impose a mandate that the analysis tools on nuclear units have the same characteristics as the analysis tools on a CT.
ISO New England		This question is unclear because the GOP is an applicable entity for NERC standards. Does a GOP need to do Network Analysis?

Organization	Yes or No	Question 7 Comment
Inc.		If that is the question, the answer is NO; a GOP must operate a Generator, the TOP / RC must do the transmission analysis.Equally inappropriate would be to impose a mandate that the analysis tools on nuclear units have the same characteristics as the analysis tools on a CT.
Response: If the eventual SDT decides to include the Generator Operator, they will constrain the applicability to only those items that directly apply. Codes and statutes will be adhered to in any eventual standard.		
Pugets Sound Energy	Yes	However, we suggest considering application of any of these standards is relative to the existance of a control center as defined or intended by the CIP standards. This would not impose an unnecessary burdan.
Response: If the eventual SDT decides to include the Generator Operator, they will constrain the applicability to only those items that directly apply.		
FirstEnergy	Yes	An SDT should always have the freedom to consider new or revised applicability in standards projects in an effort to enhance the Adequate Level of Reliability of the BES. However, in the case of this project, applicability to requirements related to real-time operating tools should only be considered for Generator Operators (GOP) with centrally located dispatch or control centers with control over multiple generation plants. The requirements must not apply to GOP located within a control room having responsibility for only a unit(s) located at a single plant location. Also, if the GOP is retained as a reliability function within the scope of this SAR, the SAR's Purpose statement should be revised to include a reference to and discussion regarding the intent of adding the GOP as an applicabe entity.Furthermore, there should be no expectation that a GOP would be performing network analysis of the BES and the standard(s) should be clear that those tools remain with the RC and TOP.
Response: If the eventual SDT decides to include the Generator Operator, they will constrain the applicability to only those items that directly apply.		
NorthWestern Energy	Yes	NorthWestern Energy agrees that a potential Standards Drafting Team should have the freedom to consider the GOP as an applicable entity. However, close consideration should be given to the NERC Functional Model to ensure that the focus of the proposed standard truly applies to a GOP or any NERC Registered Entity. Furthermore, the final decision on this matter should still reside with NERC.
Hydro One	Yes	A lack of situation awarness, alarms and telemetry that ends up with a generator(s) contingency will have an impact on the reliability of an area so it is as important.
Edward Stein (self)	Yes	Although these GOP requirements should be part of the interconnection agreement between the Generator and the Transmission Provider, it may be more straight forward to have these requirements addressed in this SAR.

Organization	Yes or No	Question 7 Comment
NERC RTOSDT	Yes	The RTOSDT can see no reason to preclude the adding of the GOP at the SDT phase of the project.
City of Tallahassee	Yes	Generator data is an important set of data for real time modeling.
ReliabilityFirst Corporation	Yes	
Manitoba Hydro	Yes	
Duke Energy	Yes	
Consumers Energy Company	Yes	
Kansas City Power & Light	Yes	
Northeast Power Coordinating Council	Yes	
Utility Services LLC	Yes	
Alberta Electric System Operator	Yes	
Con Edison System Operation	Yes	
WECC Reliability Coordination	Yes	

Organization	Yes or No	Question 7 Comment
Southern Company	Yes	
PacifiCorp	Yes	
Bonneville Power Administration	Yes	
Response: Thank you for your response.		

8. Do you believe the proposed requirements should reside in a reliability standard or should be addressed as part of the certification process?

Summary Consideration: According to the comments received, the industry was evenly split on this issue.

Certification is a one time process. New certification criteria do not apply to entities that have already been certified. There is no re-certification process nor are there any plans that the SAR DT is aware of to expand the certification process to include re-certification. Certification only proves that an entity had the functionality at a single point in time. There is no operational history associated with certification; therefore, certification criteria that deal with Real-time operations or data are only evaluated by the certification team to determine if the entity has adequate functionality to go operational. Certification relies on the Compliance Monitoring and Enforcement Program (CMEP) to prove compliance for this functionality on an on-going basis. However, CMEP can only evaluate compliance to requirements defined in the Reliability Standards. Therefore, the SAR is necessary to allow the creation of standard requirements to address the issues raised in the SAR so they will be evaluated by CMEP.

Furthermore, there are 2 directives in FERC Order 693 relating to tool capability that need to be addressed. The existing projects that would have handled these issues (Project 2006-02 for IRO-002 and Project 2007-03 for TOP-006) have clearly indicated that they expect this SAR (Project 2009-02) to address the issues raised by FERC. It is difficult to perceive how any additions or changes to the certification process could come up with a solution that would satisfy and sustain a mandatory and enforceable status for those directives. Therefore, this SAR needs to move forward or the existing projects need to take back the responsibility for addressing the directives.

The approach taken by the Standards Development Program is not to write new requirements that assess basic capabilities used to achieve performance measured through other requirements within the Reliability Standards. The SAR DT has researched the standards and concluded that other requirements do not presently exist to adequately cover the issues raised in the SAR.

This SAR is the logical place and method for starting this process.

Organization	Reliability Standard or Certification Process	Question 8 Comment
NERC RTOSDT	Certification Process	Discussions at the RTOSDT have generally yielded consensus that these are basically one-time requirements, at certification time, and which specify the "designed-in" level of performance, while not focusing on the actual performance in absolute terms. That is, any actual performance requirements should be statistically sound. For example, it is patently absurd to believe that BAL-005-0.1b R8, which requires ACE calculation at least every 6 seconds, is actually possible with real computer systems. On a design basis, this means that a hot backup with failover within a couple of minutes is required. On an actual performance basis, this is far better than the up-time

Organization	Reliability Standard or Certification Process	Question 8 Comment
		required of space shuttle computers. Something like 2 sigma or 3 sigma performance for actual results is quite possibly all that is needed for the uptime for these tools.
Electric Market Policy	Certification Process	
SERC OC Standards Review Group	Certification Process	First and foremost, the requirements developed as a part of this SAR must focus on capability, not specific technologies. The BES must not follow the path of the nuclear industry which suffers today from having specific technologies designated in the plant design basis. Technologies are progressing faster than a requirements process can follow. Embedding a specific tool in certification also creates measurement difficulty as the state of the art advances, which further supports our assertion that specifying capability rather than technology is the correct approach.
MRO NERC Standards Review Subcommittee	Certification Process	Please describe what the certification process is? Would this be for entities who wish to be registered as a BA, RC or TOP? Perhaps NERC could formulate a training program concerning these issues and give it to "all" entities to incorporate into their training programs. It would make a bigger impact vice having this SAR (and later proposed standard) be pushed around for many years before the Commission ever see it. If this is an Event recommendation, and it has taken 4 years to get a SAR, we have one slow process. Hire a contractor, put together a program based on the RTBPTF recommendations and allow All NERC Registered entities to train on it.
IRC Standards Review Committee	Certification Process	First of all, we do not agree with creating a standard for tool characteristics or performance levels. If monitoring, alarming and analysis capabilities of an entity need to be specified and complied with, then we'd suggest that the certification process be used with the certification scope and requirements so clearly stipulated that the entity must demonstrate it has acquired such capabilities to perform the assigned tasks. The capability requirements are "one of" assessment. As such, they should be a part of the certification process, not an on going assessment of proper behavior or performance level of an entity which is more suited in a standard.
Southern Company	Certification Process	These requirements need to be included in an entity's certification process that includes periodic re-certification. This would require entities to certify that they have the tools needed to perform these functions and mechanisms in place to continue to perform the functions.
American Transmission Company	Certification Process	and re-certification process

Organization	Reliability Standard or Certification Process	Question 8 Comment
CenterPoint Energy	Certification Process	See response to Q1.
American Electric Power	Certification Process	It is AEP's belief that that reliability issues that this SAR intends to address are not resulting from a void in the reliability standards, but instead in the current NERC functional entities certification processes. A participant should have, upfront, at least the tool set to operate at an adequate level. The certification process is the appropriate forum for checking the systems. Furthermore, the NERC functional entities certification process could provide periodic checks to maintain certification by ensuring that the tool set remains in place. The upfront verification becomes a must as one considers that potentially thousands of non-traditional generation facilities may be interconnected in the near term.
ReliabilityFirst Corporation	Certification Process	
Duke Energy	Certification Process	We believe that the high level requirements for functionality should be in the reliability standards, and that the certification process should contain performance metrics and procedures related to change management, maintenance coordination and failure notification. See response to question #1.
Entergy Services	Certification Process	Entergy supports the SERC OC comments.
Exelon; ComEd, PECO and Exelon Generation	Certification Process	Exelon believes the Certification Process as specified in the ROP, Organization Registration and Certification Manual, Appendix 5, would be the best way to verify that entities performing the reliability functions are adequately equipped to do so.
E. On U.S.	Certification Process	Certified entities have been determined as capable of meeting the all applicable requirements. A new standard setting forth requirements for the tools employed by registered entities to meet existing requirements is redundant. Moreover, having NERC establish either functional or technical specifications for real-time systems will stifle innovation and unnecessarily lead many entities, who are currently meeting existing requirements, to invest resources in altering and not necessarily improving their existing real-time tools. It is better to leave the development of functional and technical specifications of rapidly changing technology to buyers and responding vendors. A failure on the part of registered entities to employ adequate real-time systems will in all likelihood lead to non-compliance with one or more existing requirements. It is nonsensical to describe a system that enables its owner/operator to meet BES reliability requirements as in any way insufficient.

Organization	Reliability Standard or Certification Process	Question 8 Comment
RRI Energy	Certification Process	
ISO New England Inc.	Certification Process	First of all, we do not agree with creating a standard for tool characteristics or performance levels. If monitoring, alarming and analysis capabilities of an entity need to be specified and complied with, then we'd suggest that the certification process be used with the certification scope and requirements so clearly stipulated that the entity must demonstrate it has acquired such capabilities to perform the assigned tasks. The capability requirements are "one of" assessment. As such, they should be a part of the certification process, not an on going assessment of proper behavior or performance level of an entity which are is more suited in a standard.
New Brunswick System Operator	Certification Process	
IESO	Certification Process	First of all, we do not agree with creating a standard for tool characteristics or performance levels. If monitoring, alarming and analysis capabilities of an entity need to be specified and complied with, then we'd suggest that the certification process be used with the certification scope and requirements so clearly stipulated that the entity must demonstrate it has acquired such capabilities to perform the assigned tasks. The capability requirements are "one of" assessment. As such, they should be a part of the certification process, not an on going assessment of proper behavior or performance level of an entity which are more suited in a standard.
Northeast Power Coordinating Council	Reliability Standard	From the NERC Reliability Standards Development Procedure, "Reliability Standard" means a requirement to provide for reliable operation of the bulk power system??. The ideas proposed in this SAR meet that definition, and belong in a reliability standard. NPCC believes that the certification of a function is only a snapshot in time. With technology continuously changing, there needs to be a process that will continuously capture these changes. NPCC is of the opinion that the NERC Standards are living documents and are the best mechanism available to the industry for capturing these changes by the continuous updating of the standard's requirements included within.
Public Service Enterprise Group Companies	Reliability Standard	
Bonneville Power Administration	Reliability Standard	
FirstEnergy	Reliability Standard	

Organization	Reliability Standard or Certification Process	Question 8 Comment
WECC Reliability Coordination	Reliability Standard	
FMPA	Reliability Standard	
Edward Stein (self)	Reliability Standard	I am not sure what is meant by the certification process. I thought that the certification process was a one time deal. If the certification process is conducted annually, you may be able to not have this as a reliability standard. However if an entity loses their certification what happens to then and more important what happens to reliability.
Hydro One	Reliability Standard	
Manitoba Hydro	Reliability Standard	
Consumers Energy Company	Reliability Standard	If these requirements would reside in a certification process, they would be scrutinized only once ? during the certification process, and there would be no measurability of their ongoing presence, particularly with the demise of the Readiness Evaluation Program.
Con Edison System Operation	Reliability Standard	Reliability Standard. Not familiar with the Certication Process.
Alberta Electric System Operator	Reliability Standard	
NorthWestern Energy	Reliability Standard	Northwestern Energy would recommend putting it as a Reliability Standard only after it has been tested and proven to be effective, then the requirements can be recognized as a Reliability Standard.
Pugets Sound Energy	Reliability Standard	
Midwest ISO	Reliability Standard	The Midwest ISO believes the drafting team may need to develop both Reliability and Certification standards. Unfortunately, both options could not be selected.
Response: Thank you for your responses. Please see the summary consideration for question 8 for the SAR DT response.		

Organization	Reliability Standard or Certification Process	Question 8 Comment
MRO NERC Standards Review Subcommittee	Business Practice	Please describe what the certification process is? Would this be for entities who wish to be registered as a BA, RC or TOP? Perhaps NERC could formulate a training program concerning these issues and give it to "all" entities to incorporate into their training programs. It would make a bigger impact vice having this SAR (and later proposed standard) be pushed around for many years before the Commission ever see it. If this is an Event recommendation, and it has taken 4 years to get a SAR, we have one slow process. Hire a contractor, put together a program based on the RTBPTF recommendations and allow All NERC Registered entities to train on it.
Response: MRO appears to have submitted 2 identical comments – one for certification and 1 for business practices. The SAR DT is assuming that certification is the true response as that is in line with the question posed.		
NorthWestern Energy	Business Practice	Northwestern Energy would recommend implementing this only for RCs to test the feasibility and functionality of the established guidelines on a trial period. If the guidelines prove to be effective then it can be implemented for TOPs and BAs with detailed operational guidelines.
Response: The eventual SDT has the flexibility to ask that any standard or standard revision go through a field test prior to implementation. The eventual SDT could structure the field test to include a particular functional entity or all potentially affected functional entities.		
Utility Services LLC		neither
Kansas City Power & Light		Neither.
City of Tallahassee		While I still disagree with a need for it to be a standard, IF it is moved to the Certification process, how will you monitor it on an ongoing basis? How will you ensure the currently registered entities have the tools?
Ameren		Whether the eventual approach is determined to be new or updated Reliability Standards or changes to the Certification Process the decision should be left up to the SAR drafting team.
South Carolina Electric and Gas		The difference between a reliability standard and certification process needs to be clarified by NERC before this question can be answered.

Organization	Reliability Standard or Certification Process	Question 8 Comment
Response: Thank you for your responses. Please see the summary consideration for question 8 for the SAR DT response.		

9. If you are aware of the need for a regional variance or business practice that we should consider with this SAR, please identify it here.

Summary Consideration: No regional variances or specific business practices have been identified at this time.

Organization	Regional Variance or Business Practice	Question 9 Comment
Public Service Enterprise Group Companies		While PSEG is not aware of the specific need for a regional variance or business practice, the SAR should specify that the drafting team should consider and give deference to the long-standing requirements of RTOs and ISOs (as RC, BA, and TOP) that have maintained exemplary high levels of reliability in their areas. These RTOs and ISOs have a primary obligation to maintain reliability, and through extensive experience have mandated what real time tools are necessary to this end in their areas. For instance, PJM Manual 1 Control Center and Data Exchange Requirements provides examples of many existing requirements for real time tools, including telemetry, alarms, assurance of date integrity, etc. The drafting team should be encouraged to make use of these existing resources and ensure that the new standard does not conflict with what has proven in practice to work well.
NERC RTOSDT		N/A
Northeast Power Coordinating Council		It is to too early in the process to identify whether there will be a need for a regional variance or business practice to consider with this SAR. NPCC believes that it is premature to either determine or conclude that an impact will exist in the future.
SERC OC Standards Review Group		Neither is applicable. The reliability of the BES is only as good as the weakest link, therefore, no variances should be allowed.
FirstEnergy		We are not aware of any.
IRC Standards Review Committee		None
WECC Reliability Coordination		none at this time

Organization	Regional Variance or Business Practice	Question 9 Comment
FMPA		Not aware of any.
American Transmission Company		Not aware of anything that applies.
Edward Stein (self)		There shouldn't be any.
American Electric Power		There should not be differences in the required tool sets, based on regional differences, if the requirements stay at the “what” level.
Duke Energy		None
Con Edison System Operation		No comment.
Entergy Services		Entergy supports the SERC OC comments.
Exelon; ComEd, PECO and Exelon Generation		Not aware of the need for either.
Ameren		No comments
New Brunswick System Operator		No comment
IESO		No
Kansas City Power & Light		None.
Response: Thank you for your response.		

10. If you have any other comments on this SAR that you have not already provided in response to the prior questions, please provide them here.

Summary Consideration: The SAR has been revised to specify that any metrics will be vetted by the industry through the standards comment process. The SAR emphasizes functionality and not tools. The SAR deals only with 'what' and not 'how'.

<table>
<tr><th>Organization</th><th>Question 10 Comment</th></tr>
<tr><td>NERC RTOSDT</td><td>FERC Order 693, paragraphs 1659 to 1665, mandate the addition of a requirement in the TOP standards for a minimum set of analytical tools for carrying out TOP reliability functions and that relay closing phase angle data be presented to operations staff: Tools and capabilities are a very broad, yet specialized topic that demands industry input of a more focused nature than that possible in current Project 2007-03 (Real-time Operations) upon which the RTOSDT is working. The RTOSDT believes that the Subject Matter Experts (SMEs) that will be gathered in support of this SAR will be better qualified to address this issue, and to elicit industry input, than the operational SMEs supporting Project 2007-03. The RTOSDT is basing its response to FERC for this matter on this item being vetted and supported by Project 2009-02 as appropriate.</td></tr>
<tr><td colspan="2">Response: The SAR DT appreciates your support and will continue to work to get the SAR approved which will address the issues raised in your comment. However, the SAR emphasizes functionality as opposed to specific tools. This SAR does not handle data so the comment on relay closing phase angle data is not being considered by the SAR DT and should be handled within your Project 2007-03.</td></tr>
<tr><td>Northeast Power Coordinating Council</td><td>NPCC believes that this SAR serves as only a beginning for addressing Real Time Tools and should not be construed as all encompassing. What is the intention for addressing the input devices for these tools (i.e.--current transformers, potential devices, transducers)?</td></tr>
<tr><td colspan="2">Response: The SAR DT agrees that this SAR should not be considered as all encompassing. It is not the intent of this SAR to address input devices.</td></tr>
<tr><td>Bonneville Power Administration</td><td>The Final report from the given link is missing the detailed data sections (everything after the introductions page 36).This requires minimum standards for tools - this is GOOD to have and the tools should be used.

There should be a recognition of the effort to keep some of the tools working.

Some of the requirements are overly prescriptive - not necessary with respect to external Interchange data.

Not enough discrimination between primary entity EMS communication and ICCP exchange with external entities, which are mostly indirect reliability issues.</td></tr>
</table>

Organization	Question 10 Comment
	There should be allowance for maintenance of the equipment: primary and secondary. The ICCP is sometimes handled over communications paths not under maintenance control of the TOP/BA. Sometimes equipment may break in unusual ways and take longer to diagnose and repair than the proposed criteria allowances would allow. Diagnosing the state estimator failure takes more time than the proposed criteria allows. The criteria is unrealistic in not recognizing that, as well as the orders of magnitude for a number of additional telemetered points required to reduce it. It's good to have frequent solutions, but it's not necessary to "measure it" and to penalize if it doesn't while diagnosing the trouble. This requires an increase in 24/7 staff to manage to the proposed criteria, but still takes time to diagnose/correct failed solutions. The contingency criteria is dependent on the state estimator, so there could be double jeopardy on proposed violations.
Response: The RTBPTF Report is available on the NERC web site. **(http://www.nerc.com/filez/rtbptf.html)** Maintainability is included as a part of the SAR. The SAR is not the RTBPTF Report. It is a standalone document. There are no requirements at this time; they would be developed by the eventual SDT. At the SAR level, the SAR DT does not feel that there should be any discrimination. The eventual SDT should have the freedom to discriminate or not to discriminate as needed. The eventual SDT would have the capability to decide on allowances for maintenance. Someone is always responsible. This is normally handled in contracts. The eventual SDT would have the capability to decide on equipment repair criteria. There is no criterion at this time. This is a standalone SAR and is not the RTBPTF Report. The eventual SDT is bound by the language of the SAR and not what was in the Report. The SAR has been revised to specify that any eventual metrics will be vetted by the industry through the standards comment process. Furthermore, the SAR does not mention any tools but emphasizes functionality.	
FirstEnergy	1. This SAR should be careful to avoid development of redundant requirements that describe the tasks performed by responsible entities that rely upon the real-time tools. There are a number of existing standards with requirements already aimed at addressing alarming, telemetry, and network analysis within the BAL, COM, IRO, and TOP family of standards. To the extent the drafting team considers putting end-result expectations within new real-time tools standard(s) as proposed by this SAR, these existing requirements should also be reviewed to consider moving them to the new standard(s). Alternatively, in lieu of creating new standard(s), the existing standards mentioned above could be considered for revision to describe the minimum technical expectations and management of the real-time tools as proposed by this SAR. 2. This SAR appears to be sharply focused on addressing aspects of alarming, telemetry and network analysis. The SAR DT should consider the May 5, 2009 report provided by the Chair of the NERC Operating Committee (OC), Gayle Mayo, titled "Operating Committee

Organization	Question 10 Comment
	Report to Board of Trustees Technology Committee: Management of NERC Reliability Tools". The OC's report describes real-time tools that NERC manages that are relied upon by registered entities and the potential conflict of NERC managing the tools while also having responsibility for enforcing compliance enabled by the tools. The interim proposed solution recommended to establish a joint industry/NERC management group as an independent arm of NERC reporting to the NERC BoT. To the extent any of the reliability tools described in the OC's report have bearing on the focus of this SAR, it may be necessary to include requirements within the proposed standard(s) to adequately cover the OC's vision and responsibility of the proposed independent real-time tools management group. Additionally, the SAR DT should consider if applicability changes are needed within the proposed standard(s) to address the OC's proposal.
Response: 1. The SAR has been revised to allow for the possibility of revising existing standards. 2. The SAR can't deal with proposed changes such as mentioned here. It can only deal with what is in place at this time. Any future changes to management of tools at NERC would need to be handled when a final determination is made.	
MRO NERC Standards Review Subcommittee	Use of industry groups such as the Transmission Owners and Operators Forum, and EPRI should be considered in development of best practices, guidelines, and tools for use in real time operations.
Xcel Energy	Use of industry groups such as the Transmission Owners and Operators Forum, and EPRI should be considered in development of best practices and tools for use in real time operations.
Response: The Transmission Owners and Operators Forum (TOOF) is a private group with confidential documents. TOOF can always submit comments as a group for consideration in the standards development process. EPRI reports are generally private documents for members only. The SDT would consider any inputs available to them.	
IRC Standards Review Committee	There are numerous existing requirements for the RC, TOP, and BA to perform analysis and studies. Having these studies performed with what works best for the individual entity is important for reliability, not how they performed the study and analysis. The goal of a solid NERC Standard should be focused on the outcome.
ISO New England Inc.	There are numerous existing requirements for the RC, TOP, and BA to perform analysis and studies. Having these studies performed with what works best for the individual entity is important for reliability, not how they performed the study and analysis. The goal of a solid NERC Standard should be focused on the outcome.
IESO	There already exist a number of standard requirements for the RC, TOP, and BA to conduct analyses and studies. Having these studies performed with what works best for the individual entity is essential for reliability, not how they performed the study and analysis.
Response: The SAR DT agrees and this is why the SAR deals only with 'what' and not 'how'.	

Organization	Question 10 Comment
WECC Reliability Coordination	We have an overall concern that an implementation process needs to be coordinated to minimize the impact to organizations that do not have the current resources or dollars to immediately implement the proposed changes. Also, it appears the SAR requires specific procedures rather than guidelines for event mitigtion, which does not provide the operator or RC leaway to assess all the variabiles in the interconnection. The role and responsibility for each requirement also needs to be clearly defined.
Response: The standards development process mandates that an Implementation Plan be filed as part of any standard development. The eventual SDT would decide on the exact implementation timeframes. The SAR does not mention event mitigation. The title and wording of the SAR has been revised to provide greater clarity as to the intent of the SAR DT. The eventual SDT would define roles and responsibilities consistent with the approved Functional Model.	
FMPA	Please do not confuse the roles of TOPs, BAs and RCs. A BA should not be required to have a contingency analysis tool of transmission lines since that is not their function. A TOP should not be required to monitor supply and demand balance since that is not their function. Clearly delineate what is required of each entity.
Alberta Electric System Operator	Should consideration of applicability to the network analysis requirements be given to those entities that have a minimal impact on the BES?
Response: The eventual SDT would decide what entities are applicable for specific requirements.	
City of Tallahassee	- I must reiterate that a fully functional Network Analysis tool (Contingency Analysis) is a “Best Practice” and not a requirement for many TO’s and BA’s. I know of a case where the TO is not allowed to vote on Standard development because they do not own enough miles of transmission lines, but they would have to have a CA program by this SAR. - The following comments are directly related to the Real-Time Tools Survey Analysis and Recommendations (Final Report) but do apply to the SAR. - Too wide of a “wide area view” may be detrimental to many TO/BA’s also. If the RC is watching over the entire RC area, and the TO/BA is watching over a smaller portion with a large portion equivalized, and the RC’s model goes down because of bad telemetry in another part of the RC area, the TO/BA’s model may still be functional because it is not reliant upon the bad data for proper operation. - On page 27 of the Executive Summary, the RTBPTF identifies the need to address the definition of the Bulk Electric System. This should be done before any additional standards requiring the use of the definition are allowed to proceed. There is still not a good understanding of what it needs to be to ensure that it is reliable. Lets get this hurdle crossed before we make more references to it. - On page 17, Situational Awareness Practices: The first sentence “The task force concludes that documented conservative operations practices are a key element of situational awareness practices and thus includes conservative operations plans in its recommendations.” This recommendation appears contrary to the desires of FERC to operate closer to the edge to allow maximum trade to occur based on the ATC standards undergoing revision/review. We should not have competing standards. - On

Organization	Question 10 Comment
	page 25, Awareness of Load-Shed Capability: This "awareness" does no good if the operator does not pull the trigger. THIS is the major cause of the August 14, 2003 blackout and a recurrent theme of recent blackouts. The "word on the street" (from Compliance) is that if you have to shed load (an event), you will be investigated for compliance violations because you must have done something wrong to get to that condition. What message is that sending to the operators? - On page 29, Issue #6: Adequate Funding for Staffing for Real-Time Tools and Support Should be Ensured. This area could not be analyzed by the RTBPTF. However, it did not preclude them from making numerous recommendations to enact the Real-Time tools. I do not like creating standards or requirements without any idea of how it will financially impact entities. This WILL cost a significant amount of money to enact. While many entities (as evidenced by the participation in the survey") are already engaged in pursuing these standards, or want to, the financial burden created by making it mandatory and enforceable will have deleterious effect on reliability. The money is going to come from somewhere. Be it from rate increases or diversion of funds from other projects, delaying the construction needed to fix what is going to be shown on the CA program. The managers of the Reliability Entities are fully aware of the importance of supporting NERC Standards.
Response: The SAR emphasizes functionality, not specific tools. As far as the SAR DT knows, any registered entity is allowed to join a ballot pool. This is not the RTBPTF Report. This is a standalone SAR. The time to comment on the RTBPTF Report is long past. The eventual SDT will not be bound in any way to the RTBPTF Report but to the SAR wording.	
Duke Energy	The drafting team should be very careful not to replicate requirements in multiple standards. For example TOP-008-1 Requirement R4 currently states: "The Transmission Operator shall have sufficient information and analysis tools to determine the cause(s) of SOL violations. This analysis shall be conducted in all operating timeframes. The Transmission Operator shall use the results of these analyses to immediately mitigate the SOL violation."
Response: The SDT has a charge in their delegated responsibilities to avoid duplication of requirements.	
NorthWestern Energy	As mentioned in the Real-Time Tools Survey Analysis and Recommendations Final Report (dated March 13, 2009), "RTBPTF believes that mandatory requirements for real-time tools for reactive reserve monitoring would be highly desirable; however, before such recommendations can be formulated, NERC must define technically justified and feasible-to-implement requirements for determining the appropriate amount and location of acceptable reactive reserves and clarifying how reliability coordinators should monitor these reserves." NorthWestern Energy believes that the same should hold true for alarms, telemetry, and network analysis. First guidelines, in these areas, should be established by NERC; then once implemented and proven effective by Reliability Coordinators these guidelines can be passed down to Transmission Operators and Balancing Authorities.
Response: Guidelines are not enforceable. The SAR has been revised to specify that any metrics will be vetted by the industry through the standards comment process.	
Midwest ISO	The Midwest ISO believes this SAR and resulting standard should address what is required in terms of backup tools or more conservative

Organization	Question 10 Comment
	operations when a tool is unavailable because no tool has 100% availability.
Response: The SAR has been revised to specify that any metrics will be vetted by the industry through the standards comment process. The SAR emphasizes functionality and not tools.

NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION

Standard Authorization Request Form

Title of Proposed Standard: Project 2009-02: Real-time Reliability Monitoring and Analysis Capabilities	
Original Request Date: June 4, 2009	
Revised Date: January 15, 2010	

SAR Requester Information	**SAR Type** (*Check a box for each one that applies.*)	
Name: Jack Kerr	X	New Standard(s)
Primary Contact: Dominion Virginia Power	X	Revision to existing Standard
Telephone: 1.804.273.3393 Fax: 1.804.273.2405	☐	Withdrawal of existing Standard
E-mail: jack.kerr@dom.com	☐	Urgent Action

Purpose (Describe what the standard action will achieve in support of bulk power system reliability.) The new or revised standard(s) will establish requirements for the functionality, performance, and change management of Real-time capabilities for Reliability Coordinators, Transmission Operators, Generator Operators, and Balancing Authorities for use by their System Operators in support of reliable System operations.

Industry Need (Provide a justification for the development or revision of the standard, including an assessment of the reliability and market interface impacts of implementing or not implementing the standard action.)

According to the *Final Report on the August 14, 2003 Blackout in the United States and Canada: Causes and Recommendations,* dated April 2004, a principal cause of the August 14 blackout was a lack of situational awareness, which was in turn the result of inadequate reliability tools. In addition, the failure of control computers and alarm systems, incomplete tool sets, and the failure to supply network analysis tools with correct System data on August 14 contributed directly to this lack of situational awareness. Also, the need for improved visualization capabilities over a wide geographic area has been a recurrent theme in blackout investigations.

Recommendation 22 of the Blackout Report states "Evaluate and adopt better real-time tools for operators and reliability coordinators." NERC's Operating Committee formed the Real-time Tools Best Practices Task Force (RTBPTF) to evaluate real-time tools and their usage within the industry. The Task Force produced a report "*Real-Time Tools Survey*

Analysis and Recommendations", dated March 13, 2008 that included recommendations for the functionality, performance, and management of Real-time tools.

There are 2 directives in FERC Order 693 relating to minimum tool capabilities that need to be addressed. One directive pertains to IRO-002 and is described in paragraphs 905 & 906 of Order 693. The second directive pertains to TOP-006 and is described in paragraph 1660. These directives clearly indicate the desire for a minimum set of capabilities as opposed to specific tools. The existing projects that would have handled these issues (Project 2006-02 for IRO-002 and Project 2007-03 for TOP-006) have clearly indicated that they expect this SAR (Project 2009-02) to address the issues raised by FERC.

This SAR addresses selected recommendations in the RTBPTF Report as determined by the Real-time Best Practices Standards Study Group: Project 2009-02 and addresses the directives in Order 693 referenced above.

Brief Description (Provide a paragraph that describes the scope of this standard action.)

The scope of the SAR is to establish requirements for the monitoring and analysis capabilities provided to System Operators and used to support Real-time System Operations. The SAR addresses availability parameters, performance metrics, and procedures for failure notification, maintenance coordination, and change management. The intent is to describe 'what' needs to be done but not 'how' to do it.

Detailed Description (Provide a description of the proposed project with sufficient details for the standard drafting team to execute the SAR.)

Develop or revise standard(s) to describe the capability characteristics, such as availability parameters, performance metrics, and procedures for failure notification, maintenance coordination, and change management (vetted by the industry through the Reliability Standards comment process)of functionality for:

- Monitoring power System data in Real-time.
- Exchanging power System data in Real-time.
- Emitting Real-time visible and audible signals to alert System Operators to events and conditions affecting the state of the Bulk Electric System (BES). This functionality shall include an independent process monitor (e.g., watchdog).
- Determining the current state of the BES.
- Evaluating the impact of 'what if' events on the current or future state of the BES.

Reliability Functions

The Standard will Apply to the Following Functions *(Check box for each one that applies.)*		
X	Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area view.
X	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports Interconnection frequency in real time.
☐	Interchange Authority	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced interchange schedules between Balancing Authority Areas.
☐	Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area.
☐	Resource Planner	Develops a >one year plan for the resource adequacy of its specific loads within a Planning Coordinator area.
☐	Transmission Planner	Develops a >one year plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator area.
☐	Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).
☐	Transmission Owner	Owns and maintains transmission facilities.
X	Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
☐	Distribution Provider	Delivers electrical energy to the End-use customer.
☐	Generator Owner	Owns and maintains generation facilities.
X	Generator Operator	Operates generation unit(s) to provide real and reactive power.
☐	Purchasing-Selling Entity	Purchases or sells energy, capacity, and necessary reliability-related services as required.
☐	Market Operator	Interface point for reliability functions with commercial functions.
☐	Load-Serving Entity	Secures energy and transmission service (and reliability-related services) to serve the End-use Customer.

Reliability and Market Interface Principles

Applicable Reliability Principles *(Check box for all that apply.)*	
X	1. Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
X	2. The frequency and voltage of interconnected bulk power systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
X	3. Information necessary for the planning and operation of interconnected bulk power systems shall be made available to those entities responsible for planning and operating the systems reliably.
☐	4. Plans for emergency operation and system restoration of interconnected bulk power systems shall be developed, coordinated, maintained and implemented.
X	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk power systems.
☐	6. Personnel responsible for planning and operating interconnected bulk power systems shall be trained, qualified, and have the responsibility and authority to implement actions.
X	7. The security of the interconnected bulk power systems shall be assessed, monitored and maintained on a wide area basis.
☐	8. Bulk power systems shall be protected from malicious physical or cyber attacks.

Does the proposed Standard comply with all of the following Market Interface Principles? *(Select 'yes' or 'no' from the drop-down box.)*
1. A reliability standard shall not give any market participant an unfair competitive advantage. Yes
2. A reliability standard shall neither mandate nor prohibit any specific market structure. Yes
3. A reliability standard shall not preclude market solutions to achieving compliance with that standard. Yes
4. A reliability standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards. Yes
